MACMILLAN & CO., Ltd., LONDON.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, PADDINGTON, W. LECTURER ON CHEMISTRY.

Applications for the above Post are invited on or before WEDNESDAY JULY 6, 1904.
Salary £150 per annum (with some extra fees).
Particulars as to duties on application.

H. A. CALEY, M.D., F.R.C.P., Dean.

LONDON COUNTY ASYLUM, HANWELL, W.

The Sub-Committee for the control and management of the above-named Asylum are prepared to receive offers for the Purchase of TAR and AMMONIACAL LIQUOR for the twelve months ending JUNE 30, 1905.

Terms, cash on removal. Forms of Tender, with estimated quantities for sale, may be obtained on application to the Resident Engineer at the Asylum.

Tenders must be sent in sealed covers, endorsed "Tender for Tar and Liquor, Hanwell Asylum," to the undersigned by or before 10 o'clock a.m. on SATURDAY, JULY 2, 1904.

The Sub-Committee do not bind themselves to accept the highest or any Tender.

R. W. PARTRIDGE,
Clerk of the Asylums Committee.

London Asylums Committee Office,
6, Waterloo Place, S.W.,
June 15, 1904.

BOROUGH OF SWANSEA TECHNICAL COLLEGE.

LECTURER IN METALLURGY.

Applications are invited for the above Lectureship. Salary £200 per annum, rising by annual increments of £10 to £250.

The Lecturer will be expected to enter upon his duties in September.

Applications, with one set of copies of testimonials, should reach the undersigned not later than THURSDAY, JUNE 30th.

Further particulars can be obtained from the SECRETARY at the College.

J. TREVOR OWEN, M.A., Principal.

UNIVERSITY COLLEGE of WALES, ABERYSTWYTH.

ASSISTANT LECTURER and DEMONSTRATOR IN
CHEMISTRY.

The Council invite applications for the Post of ASSISTANT LECTURER and SENIOR DEMONSTRATOR in CHEMISTRY.

Applications, together with copies of testimonials, should reach the undersigned, from whom further particulars may be obtained, not later than SATURDAY, JULY 9, 1904.

T. MORTIMER GREEN, Registrar.

June, 1904.

UNIVERSITY OF BIRMINGHAM.

The Council invites applications for the following Appointments:-

ASSISTANT LECTURER in MATHEMATICS.

ASSISTANT LECTURER and DEMONSTRATOR in PHYSICS.

ASSISTANT LECTURER and DEMONSTRATOR in CHEMISTRY.

The stipend in each case will be £150 per annum.

The Candidates selected will be required to enter on their duties on October 3rd next.

Further particulars may be obtained from the undersigned, to whom Applications, accompanied by six copies of testimonials, should be sent not later than AUGUST 1st, 1904.

GEO. H. MORLEY, Secretary.

BRYAN CORCORAN LIM.

MILLSTONE BUILDERS.

31, MARK LANE, LONDON.

RADIUM ON SALE AND LET ON HIRE.—Write for terms.

The following can be had by return of post.

Pitchblende, direct from Joachimsthal, very radio-active, from 1/- to 30/- per piece.

Itacolomite, or flexible sandstone, 10/- to 25/- per piece (very rare).

Kunzite, 1/- per gramme. Selected, clear, 2/-

Spartelite (see NATURE, 31/3/04, fol. 523), 2/- and upwards.

Chlorophane, 2/- and upwards Barium Platino Cyanide in large Crystals in course of manufacture. (ORDERS BOOKED).

Zinc Sulphide. Phosphorescing a beautiful Green, 2/6 per tube.

" " " Yellow, 2/6 "

Calcium Sulphide " " Violet, 1/- "

Radio-active Residue from which Radium is made; very scarce, 2/- tube.

Polonium Sulphide, in tubes of one gramme, 21/-

" on Bismuth Rod or Disc, ... 25/-

" on Copper " " " 25/-

Radio-active Screens (Willenite), 6d. per sq. inch. Plat. Bar.

" " (Zinc Sulph.), 9d. per sq. inch.

" " " (Zinc Sulph.), 10 x 10 cm. 7/6.

Professional Men, Universities, Schools, &c., allowed special terms

Our newly invented Thorium Inhalers may be had on hire.

ARMBRECHT, NELSON & CO., 71 & 73 DUKE ST., GROSVENOR SQ., LONDON, W.

Telephone: GERRARD 492.

N.B.—We have to-day received a consignment of the New Zealand Vegetable Caterpillar; it is from 2 to 3 inches long, with a stem showing fructification growing out of its head. Scientific name of the insect is *Heliphus virescens*; the name of the fungus is *Sphaeria Robertiana*. Specimens may be had from 10/6 to 21/-, according to quality and size.

TERMS CASH WITH ORDER.

Goods may be returned if not approved of, when money will be refunded.

Perfect Order amongst your Scientific Papers, Research Records, &c., IS SECURED BY THE "STOLZENBERG" SYSTEM OF FILING.

The "Unit" of the System is a simple Flat File, made in six distinct colours, for classifying under Subjects, &c.

Used by SIR WILLIAM CROOKES, LORD KELVIN, Royal Commission on Tuberculosis, Baden Aniline Works (50,000), and by thousands of private persons as well as Business Concerns.

Satisfaction guaranteed; otherwise goods taken back and money returned.

Sample Set, consisting of 12 best Files, 4to and fcap., with strong nickel-plated Perforator, and Patent Lifter, packed in leather-board box, 10/6 post free.

THE STOLZENBERG PATENT FILE CO.,
50, Bishopsgate St. Without, London, E.C.

VOL. LXXXIX., No. 2326.

THE

SPECTRUM OF THE RADIIUM EMANATION.*

By Sir WILLIAM RAMSAY, K.C.B., F.R.S.,

and
Prof. J. NORMAN COLLIE, F.R.S.

ATTEMPTS have been made since July, 1903, to see and map the spectrum of the emanation from radium, for at that date the conversion of the emanation into helium was observed by Ramsay and Soddy, and during the first discharge of the induction current through the emanation, it was believed that a peculiar spectrum was noticed; indeed, three lines were persistent, and were mentioned in the communication on the subject in the *Proceedings*.

But such attempts have uniformly failed; at the first moment of the discharge, indeed, a brilliant spectrum has twice been observed, which soon became confused and indistinct. It faded before it was possible to map it, and owing to the presence of impurities, generally carbon monoxide, nitrogen, or hydrogen, the special spectrum was obscured. All that could be said was that it appeared to present some brilliantly green lines.

These experiments, however, have not been fruitless; they have led to better knowledge of the precautions which it is necessary to take to eliminate impurities. The arrangement of the apparatus, too, has been simplified, and the manipulation made easier. As it is possible that others may wish to repeat the experiments, and may perhaps have even better success in mapping the spectrum, we think it well to enter into the details of the manipulation somewhat minutely, and to give a woodcut of the apparatus employed.

The stock of radium bromide (about 100 m.grms.) dissolved in about 10 c.c. of water in two small bulbs was attached by sealing to a small Töpler's pump. Between the pump and the bulb there was a stop-cock, greased of course, to ensure freedom from leakage, but in order to prevent the long contact of the emanation with the stop-cock, and its possible contamination with carbon dioxide, the mercury from the pump was caused to flow past the stop-cock by raising the reservoir of the pump and closing the exit tube at its lower end; the mercury slowly leaked past the valve of the pump, passed the tap (which was then shut), and so confined the space above the radium bromide by means of mercury. As radium bromide yields electrolytic gas, containing an excess of hydrogen, the pressure gradually rose; the mercury in contact with this gas remained perfectly bright, and showed no tendency to adhere to the glass; the presence of ozone thus appears to be excluded, but this excess of hydrogen will form the subject of a future communication.

The emanation was allowed to accumulate for fourteen days. The pump was exhausted until no trace of a bubble passed down the capillary exit tube. But as even then a trace of air must have remained in the barrel, the tap leading to the bulbs containing the radium bromide was turned rapidly, so as to admit a trace of the electrolytic gas into the pump and "wash it out." This gas was rejected. The remaining electrolytic gas with the emanation was collected in a tube which had previously been heated to redness, and then twice washed out with pure oxygen. The mercury in the collecting tube was then boiled, and the bubble of gas removed. It was hoped thereby to have eliminated every trace of nitrogen. The gas was then introduced into the gas-burette, shown in the figure, through

the inverted syphon. All the mercury was freshly filtered and pure. The apparatus, too, was freshly constructed and heated to redness to burn out traces of dust. The gas-burette had been washed out with alkali and with nitric acid, and then with a stream of distilled water; it was dried by drawing through it a stream of dust-free air. Some slightly moist caustic potash was melted on to the glass, near the sparking wires; this was intended to absorb any trace of carbon dioxide which might have chanced to be formed during the explosion of the electrolytic gas by the burning of dust. The rubber tube was cemented on to the burette; the burette was washed out twice with oxygen, and by lowering the reservoir several times the upper end was made a torricellian vacuum; it was left thus for some time, so as to ensure the removal of adhering nitrogen from the walls of the tube.

The electrolytic gas was then introduced, and exploded. As the explosion-burette was graduated, the total volume of the gas, as well as that of the residual hydrogen, was read. There were 16.43 c.c. of gas; the residual hydrogen measured 1.01 c.c. at normal temperature and pressure, and thus amounted to 6.18 per cent of the total. The volume of this gas was increased by lowering the pressure so that it was in contact with the fused potash. It was left for more than an hour; the potash, of course, was wet with the water formed by the explosion.

The capillary tubes above the stop-cock of the gas-burette, which had been twice washed out with oxygen, were pumped as empty as possible, until the vacuum-tube showed only the yellow and green lines of the mercury spectrum and the faintest trace of a hydrogen spectrum. A strong current was passed between the electrodes so as to heat them and expel occluded oxygen. After this process had been repeated as long as was thought safe, until, as remarked, the hydrogen spectrum was extremely faint, the tap to the pump was closed. The hydrogen containing the emanation was then admitted from the explosion-burette; it was dried by passage through the narrow tube A filled with phosphoric anhydride, and it entered the bulb C,

* A Paper read before the Royal Society, May 19, 1904.

and the vacuum-tube D. This vacuum-tube was made of lead-glass, with electrodes of aluminium. It was 2.5 c.m. long, with a capillary of about 1 c.m. in length. The aluminium electrodes were closely surrounded with glass, fused round them, so as to limit the capacity of the tube as much as possible; it was probably under one-twentieth of a c.c.

Liquid air was next poured into the jacket surrounding the bulb C, and the reservoir was raised and lowered half a dozen times, so as to convey all the gas into contact with the cooled bulb. The mercury was then raised to the level *a*, and the tap to the pump opened; and while the jacket was kept replenished with liquid air the hydrogen was pumped off until its spectrum had almost entirely disappeared, the red line being hardly visible. The tap to the pump was then closed, the level of the mercury was raised to *b*, and the liquid air allowed to evaporate. The bulb was so bright that it was easy to read the time on a watch. The mercury was then raised to the level *c*, and the current passed. The spectrum was very brilliant, consisting of very bright lines, the spaces between them being perfectly dark; it had a striking resemblance in general character to the spectra of the gases of the argon group.

A direct-vision spectroscopic, made to special design by Heele, with an illuminated scale for reading, had immediately before been standardised by noting the position of the leading lines of helium and hydrogen. They were found to lie exactly on a scale which had previously been constructed. The new lines were read as rapidly as possible, an operation which required about half a minute. During a second reading many of the lines had faded, and the secondary spectrum of hydrogen began to appear, and rapidly grew stronger. It was identified by throwing into a field a hydrogen spectrum through the small prism; and it soon became so powerful as to mask the spectrum of the emanation completely. In order to attempt to recover it, the mercury was again drawn down to *a*, and liquid air again poured into the jacket; the emanation again condensed, and the tap to the pump was opened, and the hydrogen removed by the pump until its spectrum was again hardly visible. On repeating the series of operations already described, the spectrum of the emanation was seen a second time, but it was so transient that only the position of some of the lines could be confirmed.

Next day, only the spectrum of hydrogen was visible; its secondary spectrum was strong. The day after, the same was the case; but interposing a jar and spark-gap brought out two lines which had previously been mapped; they were very feeble.

In the table which follows, all the strong lines which were read are given; the degree of coincidence of those which are of known wave-length shows the approach to accuracy obtained; the error is probably less than five Angstrom units.

Wave-length.	Remarks.
6567	Hydrogen C; true wave length, 6563; observed each time.
6307	Observed only at first; evanescent.
5975	" " "
5955	" " "
5805	Observed each time; persistent.
5790	Mercury; true wave-length, 5790
5768	" " " 5769
5725	Observed only at first; evanescent.
5595	Observed each time; persistent and strong.
5465	Mercury; true wave-length, 5461.
5105	Not observed at first; appeared after some seconds; persisted, and was visible during the second examination.
4985	Observed each time; persistent and strong.
4865	Hydrogen F; true wave-length, 4861.
4690	Observed only at first.
4650	Not observed when the emanation was examined again.
4630	Ditto.
4360	Mercury; true wave-length 4359.

When the spectrum was examined two days later, besides the hydrogen and mercury lines, there were seen:—5595, feeble; 5105, feeble; 4985, very feeble; this was with a jar and spark-gap interposed; the ordinary discharge showed only the primary and secondary spectra of hydrogen, and that of mercury.

Eleven days later, the emanation from the same stock of radium bromide was collected, and treated in exactly the same manner. This time, however, an excess of conscientiousness made us continue to extract gas with the pump from the bulb C containing the frozen emanation, surrounded by liquid air, for too long a time. Every two or three strokes of the pump collected a minute bubble, occupying about the tenth of a millimetre in length of the very narrow fall tube of the pump, which was really a fine-bore capillary. The yield of gas appeared to be continuous; and when these bubbles were examined in the dark they were brilliantly luminous. This gas was really the emanation, which possesses a feeble vapour pressure even at the temperature of liquid air. Needless to say, on attempting to examine the spectrum, little was seen, for the pressure of gas in the vacuum-tube was too low.

The tube was therefore washed out with the gas which had been pumped off, and the process was repeated. The minute bubbles which passed down the capillary fall-tube of the pump were examined, and pumping was stopped when they showed a very faint luminosity in the dark. On compressing the emanation into the spectrum-tube, the spectrum was again brilliant, and measurements were made. It was found possible to read the lines several times, for although the spectrum faded in less than a minute, it appeared to recover on ceasing to pass the current. But this recovery soon failed, and, as before, nothing could be detected after five minutes but the primary and secondary spectra of hydrogen. Now the tube was practically vacuum before warming the bulb containing the emanation; no current would pass; but it is, of course, possible that the gas carrying the emanation had not been perfectly dried in passing through the tube B, containing phosphoric anhydride; any water-vapour would have condensed in the cooled bulb C, and would only slowly have vapourised into the vacuum-tube. On arriving there, it would give the hydrogen spectrum. Another possibility is that it may have come out of the electrodes; for it has been frequently noticed in glowing out a vacuum-tube with aluminium electrodes, that even after all trace of hydrogen has been removed by passing the discharge so as to heat the electrodes, and by pumping, the hydrogen spectrum has re-appeared on admitting a trace of one of the gases of the argon group, and passing the discharge for a longer time; but the intensity of the spectrum which replaced that of the emanation may perhaps warrant the supposition that hydrogen as well as helium is one of the products of the disintegration of the emanation. This, however, is very doubtful, and judgment may be suspended until more satisfactory evidence is forthcoming.

The lines read were:—

Wave-length.	Remarks.
6359	Not observed before; faint.
5975	Observed before; faint.
5955	" " "
5890	Not observed before; faint.
5854	" " "
5725	Observed before; fairly strong.
5686	Not observed before; faint
5595	Observed before; strong and persistent.
5580	Not observed before; faint.
5430	" " "
5393	" " "
5105	Bright; persistent; observed before.
4985	" " "
4966	Not observed before; bright, but transitory.
4640	Transitory; possibly 4650 and 4630, as were seen before as distinct lines.

The line 4966 was particularly brilliant at first; but it soon assumed secondary importance. Some lines which had previously been observed were not seen; they are 6307, 5805, 5137, and 4690. An attempt was made to obtain the spectrum with a jar and spark-gap; but only hydrogen and mercury were to be seen. The resistance soon became very high, and there was danger of piercing the vacuum-tube.

Previous attempts in conjunction with Mr. Soddy gave lines with wave-length 5725 (jar), 5595 (no jar), 5105 (no jar), 4985 (no jar); the line 5585 was observed three times, and 5105 twice previously. The lines 6145 and 5675 mentioned in our last paper (April, 1904) were not seen unless the latter is identical with 5580. It may perhaps be mentioned that the line 5595 was seen by Pickering in the spectrum of lightning, and was not identified with a line in the spectrum of any known gas; it is said to have been a very strong line, of intensity 30 (*Astrophysical Journal*, 1901, vol. xiv., p. 368).

There can be no doubt that the lines given are the chief lines in the visible spectrum of the emanation; as for the pressure, the volume of emanation was about $1/30,000$ th of a c.c., and the capacity of the vacuum-tube, say, $1/20$ th; this would make the pressure about $1/10$ th of a millimetre. It may have been twice as much, for the numbers given are merely estimates.

It may be remembered that, at the Chemical Congress held in Paris in 1900, it was suggested that no element should receive a name until its spectrum had been mapped. Of course, the converse does not follow that, after the spectrum of an element has been mapped, it should receive a name. The "emanation from radium," however, is a cumbersome expression, and sufficient evidence has now been accumulated that it is an element, accepting that word in the usual sense. It is true that it is only a transient element, and ought in justice to be called a compound; but of what? It stands on a wholly different plane to any known compound in the amount of heat with which it parts during its spontaneous change, and in the peculiar electrical phenomena which accompany its transformation. It is a gas; it follows Boyle's law; as Rutherford and Soddy have shown, it resembles the gases of the argon series in its indifference to chemical reagents, for it not merely withstands the prolonged action of magnesium-lime, at a red heat, but also, as Ramsay and Soddy have proved, prolonged sparking with oxygen in presence of caustic potash. Its molecular weight has been found to be nearly 200, and, if it is monatomic, that number would also express its approximate atomic weight. Now, it appears advisable to devise a name which should recall its source, and, at the same time, by its termination, express the radical difference which undoubtedly exists between it and other elements. As it is derived from radium, why not name it simply "exradio"? Should it be found that the emanation, which is supposed to be evolved from thorium, is really due to that element, and not to some other element mixed with thorium in exceedingly small amount, a similar name could be given, namely, "exthorio." If the existence of actinium as a definite element is established, its emanation would appropriately be named "exactinio." It is unlikely that others will be discovered, but, if they are, the same principle of nomenclature might be applied.

It should be stated, in conclusion, that Mr. Soddy collaborated in the experiments preliminary to this successful mapping of the spectrum; had he not been obliged to leave England, he would, no doubt, have shared whatever credit may attach to this work.

A VOLUMETRIC METHOD FOR THE ESTIMATION OF MERCURY FULMINATE.

By HENRY W. BROWNSDON, B.Sc., Ph.D.

THE use of sodium thiosulphate solution as an agent for decomposing fulminate of mercury was first brought to my notice by Mr. George Smith, manager of Nobel's Fulminate Factory at Polmont, and with a view to its adoption in this laboratory I have had the opportunity of making an inquiry into the nature of the reaction. My work in this direction is, however, still incomplete, and I now only wish to mention an analytical application which has resulted as a side issue.

When fulminate of mercury is decomposed by excess of sodium thiosulphate solution, the resulting solution reacts alkaline, and the determination of the amount of alkali thus formed affords an easy and quick volumetric method for the estimation of mercury fulminate.

Method.—The only solution required is one of sulphuric acid approximately N. 10. This is standardised as follows: 0.04 to 0.05 gm. of pure mercury fulminate—prepared by dissolving the ordinary commercial product (1 mol.) in pure potassium cyanide (1 mol.) solution, precipitating the mercury fulminate from the solution of the double salt by means of dilute nitric acid, washing several times by decantation, and finally on the filter-paper till quite free from acid, and then drying at 80 to 90°—is weighed out into a 100 c.c. flask containing about 50 c.c. water; 1 gm. of pure sodium thiosulphate is then added, the flask well shaken till all the fulminate has dissolved, and then made up to the 100 c.c. mark. Portions of 25 c.c. are withdrawn by means of a 25 c.c. pipette, and titrated with acid after addition of one drop methyl orange. It is well to allow the acid to drop from the burette drop by drop, shaking the liquid to be titrated all the time, so that no portion of the liquid becomes locally acid.

The above is repeated on three separate weighings, and the mean taken. The value of 1 c.c. H_2SO_4 in grms. of fulminate is thus obtained.

As applied to the determination of mercury fulminate in cap or detonator compositions, one precaution is necessary, viz., that the amount of fulminate in the weighed out portion of composition should not exceed 0.05 gm., otherwise the results will tend to be low on account of the alkali set free reacting with the finely divided antimony sulphide. For a cap composition containing 15 to 20 per cent fulminate, a weighing of 0.25 gm. is suitable, whilst for a detonator composition containing 35 to 40 per cent fulminate a weighing of 0.12 gm. is sufficient.

The above amount of either cap or detonator composition is weighed out into a 100 c.c. flask containing about 50 c.c. water, 1 gm. of pure sodium thiosulphate added, and the contents well agitated till one is sure all the fulminate has been decomposed (one and a-half to two minutes). The flask is then filled up to the 100 c.c. mark, the contents mixed, and filtered through a dry folded filter-paper into a dry flask. The first runnings are returned through the filter-paper till the filtrate is clear. Portions of 25 c.c. are then titrated as above. To ensure accuracy, a rough preliminary experiment is made, and then two subsequent determinations on two separate weighings, taking the mean of the two latter for the result.

The solutions must not be allowed to stand, but must be titrated as soon as possible after the addition of the thiosulphate, since after a time secondary reactions set in which neutralise some of the alkali giving low results.

Following are a few typical results obtained by applying this method to compositions containing a known weight of fulminate.

By careful working it is possible to estimate the weight of fulminate to within ± 0.0001 gm., an error which is less than 0.1 per cent when calculated out for the percentage of fulminate in the composition. I am continuing this work, and hope shortly to give a fuller account of the reaction

Technological and Scientific Dictionary.—Part III. of this Dictionary has just been issued by the publishers, George Newnes, Ltd. We have previously referred to the merits of this work, of which the present number comprises those subjects coming between C O P (Copper losses, *Elect. Eng.*), and E L E (Electric lighting), the pages running from p. 129 to p. 192.

Weight of fulminate taken.	Weight of Sb_2S_3 .	Weight of KClO_3 .	H_2SO_4 (1 c.c. = 0.00832 grm. fulminate).		Weight of fulminate found.
			First titration.	Second titration.	
Grm.	Grm.	Grm.	C.c.	C.c.	Grm.
0.0328	0.05	0.05	1.00	0.98	0.0329
0.0483	0.05	0.05	1.45	1.45	0.0482
0.0462	0.05	0.05	1.40	1.38	0.0462
0.0425	0.10	0.10	1.25	1.30	0.0424
0.0458	0.10	0.10	1.35	1.40	0.0457

along with its bearing on the composition of the fulminates, a point on which the decomposition by thiosulphate and by sodium sulphide seems to throw much light.

I have much pleasure in acknowledging here the kindness of the directors of the Kings Norton Metal Company, Limited, who have placed facilities at my disposal for carrying out this work.

A NEW MAGNESIA CUPEL.

THOSE of our readers who employ magnesia in preference to the bone-ash cupels which have for so long held the field, will be interested in an ingenious improvement which has recently been made in the Morganite cupels introduced by the Morgan Crucible Company, of Battersea.

Although the numerous advantages possessed by magnesia cupels as compared with those of bone-ash are now generally recognised, the slightly slower absorption of the litharge by the former tends to permit a portion of the litharge to soak down through the bottom before it can diffuse into the body of the cupel. Hence, before the cupels are fully saturated, a portion of the litharge is lost, and the muffle may become corroded by the litharge. The former is usually of little consequence, and the latter may be obviated by the practice which many assayers adopt, of keeping a layer of bone-ash, magnesia, or other absorbent in the muffle, but both are practically abolished by use of the new cupel.

The improvement, as shown in the accompanying sketch, consists merely in making the cupel with a cup-shaped depression in the bottom; in fact, in making it double ended. The litharge soaks through exactly as in

ordinary cupels, but as the middle portion is not in contact with the muffle floor, it has time to diffuse into the body of the cupel before it accumulates sufficiently to actually escape at the bottom.

This simple device has been found to answer all expectations. It permits of the cupellation of a larger quantity of lead per cupel without loss of litharge, and it is stated by the inventors that cupellation progresses more rapidly in these than in the old form of cupel.

As we presume that these cupels will not cost more than the old form, it may be worth while for our readers to try them and ascertain how far their experience bears out the statements of the inventors as to the results which they have obtained in practice.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING MAY 31ST, 1904.

By SIR WILLIAM CROOKES, F.R.S.,
and
PROFESSOR DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, June 8th, 1904.

SIR,—We submit herewith, at the request of the Directors, the results of our analyses of the 204 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the London Water Companies taking their supply from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from May 1st to May 31st inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 204 samples examined by us during the month, all were clear, bright, and well filtered.

There has been a large excess of rain during the month of May. The actual rainfall measured at Oxford during the month was 3.20 inches, and the average fall is 1.75 inches; thus we have an excess of 1.45 inches, which, if added to the previous excess of 0.98 inch, makes a total of 2.43 inches, or 27.9 per cent above the average for thirty-five years.

Our bacteriological examinations of 370 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 364 others from special wells, standpipes, &c., making 734 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 25 samples) ..	116
New River, filtered (mean of 74 samples) ..	4
Thames, unfiltered (mean of 25 samples) ..	4120
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 196 samples) ..	15
Ditto ditto highest	181
Ditto ditto lowest	0
River Lea, unfiltered (mean of 25 samples) ..	225
River Lea, from the East London Water Company's clear-water wells (mean of 25 samples) ..	19

Of the 295 daily samples taken from the general filter wells of the Metropolitan Water Companies, twenty-two samples, or 7.4 per cent, were sterile. Five samples, or 1.6 per cent, contained more than 100 microbes, and of these, two samples contained more than 150 microbes per c.c. The five excess samples contained an average of 143 microbes per c.c. In April five excess samples contained an average of 123 microbes per c.c.

From the above figures it will be seen that the high condition of purity observed during April has been well maintained during the month of May, in spite of the great increase of rainfall.

We are, Sir,

Your obedient Servants,

WILLIAM CROOKES.
JAMES DEWAR.

INTERNATIONAL ATOMIC WEIGHTS.*

By JOJI SAKURAI and K. IKEDA.

Science College, Imperial University,
Tokyo, Japan, May 10, 1904.

To the Editor of the *Chemical News*.

DEAR SIR,—I am sending to you by this mail a copy of the reprints of a letter addressed by my colleague Prof. Ikeda and myself to Professor F. W. Clarke on the subject of International Atomic Weights. Although the letter, which forms a part of our report to the Tokyo Chemical Society on International Atomic Weights, has been printed in the *Journal* of that Society, I shall be obliged if you can find space for its publication in your valuable journal, knowing that hundreds of the readers of the *CHEMICAL NEWS* take interest in the subject, and that the *Journal of the Tokyo Chemical Society*, which is printed in Japanese, is quite closed to the scientific world.—I am, your obedient Servant,

JOJI SAKURAI.

The following letter was addressed by us to Professor F. W. Clarke on the subject of International Atomic Weights:—

Tokyo, Japan, March 28th, 1904.

Professor F. W. CLARKE, Chairman of the Sub-committee on International Atomic Weights.

DEAR SIR,—Whilst we wish to tender our sincere thanks to you and your worthy colleagues for the laborious task of yearly reviewing and compiling the table of atomic weights for international use, we feel at the same time bound to make some observations upon the course you have adopted in prosecuting the work entrusted to you.

The first and most important point is in reference to the introduction of the double standard. We can appreciate the delicate position which you occupy with respect to this much-controverted question, and we can also understand why you chose to leave the matter to take its own course without giving decision in one way or the other. But, as you must know, the larger committee on International Atomic Weights, from which the sub-committee has been formed, had decided, by a great majority of votes, to use *exclusively* those atomic weights which are based on the oxygen standard. The introduction of the double standard is therefore utterly against the above decision, and also in direct opposition to the very motive with which the International Atomic Weights Committee has been organised; moreover, the matter has thereby become worse than ever, for there are now two sets of atomic weights which are apparently equally authorised.

But, apart from the question of the previous history which the formation of the Sub-committee possesses, and which, as it appears to us, you have wholly disregarded, we beg to call your attention to the following circumstances:—

In looking over your tables of atomic weights for 1903 and 1904, we observe that, in the numbers under $O = 16$, only so many figures are given that the last figure may also be taken as correct. That you deem the adoption of this rule, which had been adhered to by the German Committee, desirable is evident from the remark you have made with respect to $H = 1.008$ in your Report for 1903, but when we examine the atomic weights under $H = 1$ we find curious contradictions. The atomic weight of oxygen is given with only four figures—that is, $O = 15.88$ —from which we may conclude that you regard the ratio $O : H$ has been only so far determined with certainty, and not further, and we are consequently at a loss to understand how the atomic weights of iodine, lead, and silver have been evaluated to five figures, as given. Professor Morley's ratio, $O : H = 15.879$, has apparently been employed for the purpose; but then, in accordance with the principle which

made you alter $H = 1.01$ to $H = 1.008$, the atomic weight of oxygen should stand as $O = 15.879$, and not $O = 15.88$, as in your tables. This, it appears to us, illustrates in the most conspicuous manner the shortcomings of the hydrogen standard, which have already been pointed out by various chemists.

Again, on going through your tables, one is tempted to entertain the absurd notion that the atomic weights according to the hydrogen standard could be ascertained with greater accuracy than those based on the oxygen standard, for there are as many as eighteen elements whose atomic weights have more figures under $H = 1$ than under $O = 16$, while there is only one element treated in the opposite manner. Of these eighteen elements thus favourably (?) treated under $H = 1$, the majority are rare elements, whose atomic weights are avowedly less accurate than the others. What is more remarkable still is the fact that one finds phosphorus among the number—an element whose atomic weight, according to your Report, "has been peculiarly neglected." It is clear that you do not have much confidence even in the value $P = 31.0$ ($O = 16$). What sort of reliance can, then, be placed in the last figure of the value $P = 30.77$ given under $H = 1$? Are these contradictions mere consequences of re-calculation of the atomic weights under $H = 1$ from those under $O = 16$? Or are there some other reasons for the adoption of these values?

However it might have been, the lack of uniformity in the two series is lamentable. This is only one of the unhappy consequences of retaining both standards. It might perhaps be urged that the uniformity in the treatment of figures can be ensured by taking ordinary critical care in re-calculation; but the fact that such re-calculation, which, moreover, involves the uncertainty of the ratio $O : H$, is at all necessary, is a great drawback of the hydrogen standard.

As Professor Ostwald strongly protested against the adoption of the hydrogen standard directly after the appearance of your first Report, we have been waiting for the publication of your second Report in the hope of seeing it dropped. But our hopes have been denied, and we feel ourselves obliged to address this letter to you.

There is another matter which, though of less importance, cannot be allowed to pass unnoticed, namely, the alteration of the symbols Be for beryllium and Nb for niobium into Gl (glucium) and Cb (columbium) respectively, which has been introduced into your tables. That atomic symbols ought to be as much international as atomic weights has been well recognised in the use, for example, of the symbol K for potassium. There is nothing which prevents the use of one name for an element in one country and another name in another, but surely atomic symbols should not be allowed to suffer similar discrepancies. The symbols Be and Nb have been and are most generally employed all over the world; if Gl and Cb had any claim to be considered as candidates, the choice ought to have been made according to the broadest international usage.

Lastly, we would like to call your attention to the unsatisfactory state of the relation which exists between the originally formed larger committee on International Atomic Weights and the Sub-committee of which you are the worthy Chairman—or, rather, non-existence apparently of any relation whatever between the two. Members of the larger committee do not receive any report from you, nor are they told through what periodicals your report will be made known to them. The matter of history has, it appears to us, been again disregarded here.

Trusting that the points represented above may receive your due consideration, and also that we may be allowed to publish this letter,—We are, Dear Sir, your obedient Servants,

K. IKEDA,
JOJI SAKURAI, } Members of the Committee
on International Atomic
Weights, representing the
Tokyo Chemical Society.

* From the *Journal of the Tokyo Chemical Society*, April, 1904.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, June 10th, 1904.

Dr. R. T. GLAZEBROOK, President, in the Chair.

PROF. H. L. CALLENDAR gave a demonstration of the "Projection of the Indicator Diagrams of a Petrol Motor."

The lantern-slides illustrated the working of the motor under various conditions, and were prepared to elucidate the nature of some of the defects which occur in practice. The motor itself was exhibited in action, with the indicator attached, and the actual diagrams were projected on the screen showing the changes of form as they occur when the conditions of running are changed. The motor employed was a Clement-Garrard cycle-motor, with 60 m.m. bore and 70 m.m. stroke. The inlet valve is automatic, and is provided with an arrangement for varying the tension of the spring for experimental purposes when the engine is running. The indicator used was a Hospitalier-Carpentier manograph, with certain modifications which are necessary for high-speed work. It is connected directly to the cylinder by a short steel tube in place of the long fine copper tube usually employed. The pressure acts on a thin steel disc, the movements of which are communicated to a small pivoted mirror, which is tilted upwards through an angle proportional to the pressure acting on the disc. The movement of the mirror is observed or recorded by a ray of light reflected on to a screen or photographic plate. In order to record the pressure at each point of the stroke in the form of a continuous curve or diagram, the mirror is simultaneously tilted from side to side by a little crank revolving in time with the fly-wheel, so that the spot of light reflected from the mirror moves horizontally in time with the motion of the piston in the cylinder. Owing to the high speed the spot of light is seen as a continuous curve, which is readily measured or photographed. The engine works on the four-stroke cycle of operations—suction, compression, explosion, and exhaust—and runs at speeds varying from 2000 to 2500 revolutions per minute.

Prof. Callendar exhibited a series of lantern-slides showing how the characteristics of the diagram depend upon the point of the stroke at which the gases are ignited. He also demonstrated experimentally how the pressure retardation, which occurs when using a long fine copper tube to connect a high-frequency engine to a manograph, could be compensated by retarding the position of the spot of light relative to the piston by an amount equal to the retardation of the pressure at any given speed. Leakage is a fruitful source of loss of power, but it was shown that it could easily be detected by an examination of the indicator diagrams. A leak shows itself at a loop at the end of the compression-stroke if the spark is retarded, coupled with a rapid fall of pressure during expansion. The effect of overheating of the engine can be well shown by comparing two diagrams taken under similar conditions with the cylinder cold in one case, but hot in the other. The hot cylinder shows the higher compression-pressure and the smaller explosion-pressure, so that the power is diminished for both reasons.

Diagrams were shown to illustrate the effects of back pressure, due to insufficient exhaust lift or to a throttled silencer. The loss of power on this account is not very serious unless the throttling is excessive.

Prof. J. A. FLEMING read a paper entitled "A Model Illustrating the Propagation of an Alternating Current along a Telephone Cable, and a Simple Theory of the same."

Although the mathematical theory of the propagation of alternating currents along lineal conductors having capacity, inductance, resistance, and leakage has been developed by many writers in great fulness, the conclusions

reached by them have not always been readily assimilated by practical engineers, and in some cases unsound theories have been put forward regarding the conditions limiting telephonic speech along wires. The present paper contains an account of a model (exhibited at the meeting) which has been constructed by the author, for the purpose of explaining in a simple manner the physical meaning of the mathematical expressions which are reached in discussing the propagation of alternating currents along a telephone or telegraph cable. The first part of the paper is concerned with a presentation of the elementary theory of the phenomena expressed in terms of complex quantities, which forms a more suitable mode of investigation than the use of ordinary trigonometrical analysis, as the time-element is thereby eliminated. Beginning with the fundamental differential equations for the distribution of potential and current in an element of such a cable when traversed by any current, these are then thrown into the form appropriate when considering simple harmonic currents, and a solution given for the potential and current distribution in the case of a semi-infinite cable, having a simple periodic E.M.F. applied at the end. This solution is of the form $V = Ee^{-\alpha x}(\cos \beta x - i \sin \beta x)$, and it indicates that the potential, V , at any point in the semi-infinite cable has a maximum value which is less than that at the origin, (E), in an assigned ratio, and shifted backwards by an assigned angle in phase. A geometrical interpretation was then given of the above equations, leading to a graphic representation of the distribution of potential in the cable at any moment, and the model shown illustrated the meaning of the above equation and the graphic interpretation of it. The model consists of a steel axis, on which are keyed a number of wooden discs grooved on the edge. These are set on the shaft eccentrically, and the eccentricity of the wheels diminishes in geometrical progression. Each eccentric is shifted backwards in phase compared with its preceding neighbour by an equal angle, and these eccentricities and phase-angles can be varied. Each eccentric wheel is embraced by a long string, the ends of which are attached to metal blocks which can slide up and down on a steel wire. These strings are all of equal length. When the axis carrying the wheels revolves, each block moves up and down with a nearly simple harmonic motion, but the amplitude of that motion decreases from block to block, and, moreover, the phase of the motion of each block is delayed behind that of its next preceding neighbour by an equal amount. Hence, when the axis is turned round, the blocks, of which there are 48, are arranged in a periodic curve of decreasing amplitude, and move up and down in a manner which imitates the propagation of a wave of alternating current or potential along a cable. The paper then proceeds with a discussion of the theory, and a very simple proof is given of Mr. Heaviside's condition for the distortionless propagation of a wave of electric current. The criterion of distortion is then applied in the case of one long submarine cable, and it is shown how far removed such a cable is from being a distortionless cable. The remedies which have been proposed are then discussed, and it is shown that it is hopeless to expect any real advantage merely by bringing the iron armour closer to the cable-conductor, but that a large reward awaits any inventor who can bestow upon a long submarine cable inductance up to 300 or 400 henries per naut, without at the same time increasing much the usual capacity of 0.3 m.f.s. per knot. Allusion is made to Prof. Pupin's investigations concerning the insertion of inductance-coils at intervals along the telephone lines, and the suggestion is made that there is no difficulty in applying this plan to subterranean telephone trunk-lines, and that considerable improvement in the transmission of telephonic speech could thereby probably be effected.

Mr. T. H. BLAKESLEY congratulated the author upon the interesting result contained in his paper, that under a certain critical relationship, among the properties of the cable relatively distortionless waves might take place whatever the frequency. But he thought some other of the

consequences of this relationship might be more simply exhibited in the forms for potential and current,—

$$V = E e^{-\alpha x} \cos(\delta x - pt), \quad I = \frac{E e^{-\alpha x}}{q} \cos(\delta x - pt + m)$$

where—

$$q^2 = \frac{R}{K} \left(\frac{1 + \left(\frac{L}{R}\right)^2}{1 + \left(\frac{C}{K}\right)^2} \right) \quad \text{and} \quad \tan 2m = \frac{(LK - RC)\delta}{RK + LC\delta^2}$$

q is of the nature of resistance, and m is the angle of lag of the current behind the potential, and is constant for all points of the cable. This lag-angle disappears when $LK - RC = 0$, but from the expression for q^2 it is clear that this quantity will be independent of the frequency if $L/R = C/K$, which is again the same condition. Thus the real degradation of current would be the same for all tones, and the conjunction of current and potential, for all points, would be secured by this condition. It would not, however, be easy in practice to fulfil this condition. There was, however, something to be said for keeping both L and K small, as in fact they are in practice. For, looking at the expression for q^2 , it will be seen that it diminishes as the frequency rises if $CR > LK$, and this is true of cables in practice. Hence, though $e^{-\alpha x}$ grows less with rising frequency the resistance q also becomes less, so that the degradation of current is not so great as that implied in the mere increase of α with frequency. Mr. Blakesley pointed out that in operating upon equations 13 and 14 to obtain equations 20 and 21, the quantity $\sqrt{(R^2 + \delta^2 L^2)(K^2 + \delta^2 C^2)}$ could be written in two ways:— $\sqrt{(KR + \delta^2 LC)^2 + \delta^2 (LK - CR)^2}$. The author had chosen the top signs, but interesting results could be obtained by choosing the bottom signs and contemplating the equality of KR and $\delta^2 LC$.

The CHAIRMAN read a letter from Mr. Jacob pointing out that the dielectric resistance of the 1880 Anglo-American Cable, considered in the paper, is much higher, as it lies in the sea, than the figure quoted by the author, which was obtained at 75° F. and atmospheric pressure after 1 min. electrification. The electrification or absorption of the dielectric, however, masked all the effects of the high insulation value. An inductance of 300 or 400 henries per naut was beyond possibility; the inductance should not be of a higher order than one henry per naut.

Dr. FLEMING, in reply, said that the relation between the electrical constants of the cable which gave distortionless transmission was discovered and announced twenty years or more ago by Mr. Oliver Heaviside. All that he (Dr. Fleming) had attempted to do was to simplify and illustrate the proofs of this condition. The employment of complex quantities in the discussion of alternating-current problems led to a considerable simplification of the analysis. As in practice we were only concerned with the maximum or root-mean-square values of the potential and current, the introduction of the time-variable into the equations led to complicated expressions, the physical meaning of which was not readily apparent to most students. All the usual algebraic expressions for current and potential at any point could, however, be readily obtained from the vector equations he had given. As regards the practical realisation of Heaviside's distortionless conditions for submarine cables, the figures given in the paper were merely intended to indicate the remoteness of its possibility. The correction furnished by Mr. Jacob for the insulation resistance of the dielectric when the cable was immersed did not affect the general conclusions, as if the insulation resistance was greater, the departure from the distortionless conditions would be then still greater. He recognised that the "absorption" of the dielectric introduced a factor not taken into account in the mathematical theory. As regards the practical superior limit of inductance which might be given to a cable, no one could say what invention might not bring forth. He was glad

to hear that an inductance of 1 henry per naut might improve matters sensibly, because he had devised a plan by which an approximation to this might be reached. Mr. Jacob only confirmed the statement in his paper in expressing the opinion that an inductance of 300 to 400 henries per naut was impracticable.

Mr. M. E. J. GHEURY then exhibited a Gyroscopic Collimator. The instrument is used in conjunction with an ordinary sextant, the observation being taken as with the sea horizon by bringing the image of an observed body into a field of vision, in which a horizontal grating of a special kind allows the observer to ascertain the direction of the true horizon. The essential feature of the collimator is a gyrostat equivalent to a long pendulum, the period of vibration of which is very much greater than the periods of the various motions of the ship upon which it is used.

THE FARADAY SOCIETY.

An Ordinary Meeting of the Faraday Society was held on Thursday, June 9th, at the Institution of Electrical Engineers. The President, Dr. J. W. SWAN, was in the Chair.

M. ADOLPHE MINET presented the first part of a paper on "*The Electric Furnace, its Origin, Transformations, and Applications.*"

The paper discusses the growth of the furnace from the historical point of view, and then proposes a new classification, which is worked out in minute detail in the form of a table. A full bibliography of the electric furnace completes this section of the paper.

This discussion was postponed until the autumn, when the author will complete his study and fully illustrate his subject.

Dr. F. M. PERKIN described a form of Porous Diaphragm that he has found convenient for laboratory use. It consists of two perforated concentric porcelain cylinders packed in between with brown paper, asbestos, or other material, depending on the use to which the diaphragm is to be put.

Mr. G. T. BILEY read a paper on "*The Hard and Soft States in Metals.*"

The wide range of the phenomena which are directly or indirectly associated with the hard and soft states in metals indicates that a knowledge of these states is of fundamental importance. An exclusively crystalline theory of metal structure, even when stretched to its widest limits is insufficient fully to explain these phenomena. But the crystalline is not the only form of solid aggregate; the movement of the molecules in the liquid state may be so suddenly arrested that they have no time to fall into the regular formation of the crystalline state, so that the solid which results is amorphous, not crystalline. A suddenly congealed liquid may be likened to an instantaneous photograph of the rapidly moving molecules of the liquid state.

The views here advanced are based on the author's earlier observations on surface flow in crystalline solids. The evidence afforded by the micro-structure has been supplemented by observations on the other properties of metals in the hard and soft states, and the view is now advanced that these states are perfectly distinct phases. This is shown by the mechanical, electrical, optical, and thermo-chemical properties as well as by the micro-structure. The soft phase, C, is crystalline, and the hard phase, A, is amorphous.

The transformation of A into C is effected by heat, and takes place at a definite transition-temperature. On either side of the transition-point the various properties are characteristic and distinct; for instance, an E.M.F. of 120 micro-volts may be developed in a thermo-junction of silver in the two phases. The E.M.F. falls to zero after the junction has been heated to 260° for a few seconds. Silver

leaf, which is opaque and highly reflecting below the transition temperature, becomes transparent and very much less reflecting if kept for a time at a temperature a little above that point.

The transformation from hard to soft is thermally irreversible, but is readily effected mechanically. This reverse transformation—soft to hard—takes place when the metal is deformed by over-strain, however slight. It takes place through an intermediate mobile phase in which the molecules have a freedom analogous to that in the liquid phase. This freedom is produced by motion directly imparted to the molecules during the slipping of one portion of the material over another. The state of the mobile phase is somewhat analogous to that of an undercooled liquid. This transformation, C—M—A, while it occurs at every moving surface, does so, as a rule, in extremely thin layers. The layers of the hard phase which result supply a rigid casing for the unaltered crystalline elements, and thereby give a granular and cellular structure to metal which has been overstrained by having any kind of work done on it. The co-existence of the two phases in this way accounts for the variety of structure which may be developed in malleable and ductile metals.

Dr. T. M. LOWRY said that the temperature which Mr. Beilby called the transition-point was not a true *transition-point*, such as exists, for example, in sulphur at $96^{\circ}\text{C}.$, at which the rhombic passes into the monoclinic phase, but really the *stability-limit*; that is, the temperature at which the mobility of the molecules enables a change which has been trying to take place all along to do so at a visible velocity.

Mr. J. C. M. GARNETT suggested that the different results obtained in the two methods—by transmitted and reflected light—of measuring the optical constants might be explained on Mr. Beilby's hypothesis of an A and C phase.

Dr. C. M. DESCH thought that the existence of a thin transparent film on the surfaces of polished metals might explain the Kerr effect.

THE ROYAL SOCIETY.

CONVERSAZIONE AT BURLINGTON HOUSE.

ON Wednesday evening last, June 22nd, a most successful *Conversazione* was held at the Royal Society's Rooms at Burlington House, the occasion being known as "Ladies Night," and the guests were received by Sir William and Lady Huggins.

A certain number of the exhibits were shown at the last *Soirée*, on May 13, and have been already noticed in these columns.

Among the most interesting of those to be seen on Wednesday evening last we may mention a very ingenious instrument, exhibited by Mr. W. DUDELL, called the Thermo-galvanometer, an instrument for measuring very small alternating currents. The instrument is intended for the measurement of very small rapidly-varying currents, such as telephonic currents and the currents produced in the receiving vertical wire in wireless telegraphy. Signals were sent from a transmitter at the end of the main library (Room V.); the very small current produced in the vertical wire at the receiving station was measured with the thermo-galvanometer, and the great increase in the current due to tuning the receiving circuit was demonstrated. Some experiments with telephonic currents were shown. The sensibility of the instrument is such that either direct or alternating currents from a few micro-amperes upwards can be measured. The deflection is practically proportional to the mean squared value of the current flowing.

Mr. W. HIBBERT showed a new Magnetic Balance, constructed as follows:—The beam of a balance is made of a magnetised steel rod 27 c.m. long. The "centres" of the poles are 25 c.m. apart. The repellent pole of a second

magnet being placed over one end of the beam causes this to descend, and the force of repulsion is balanced by a weight sliding on the other half of the beam. The absolute value of a pole in C.G.S. units can be ascertained in a very few minutes, without reference to the terrestrial or other field. The instrument can also be used for finding the approximate value of an electric current.

A simple method for printing without the use of inks was shown by Mr. FRANCIS SHERIDAN called the *Physiotype*. It is specially adapted to finger printing and the reproduction of designs from animal and vegetable life. The subject to be reproduced is pressed on paper, and an invisible impression is developed with a coloured powder into a dark and permanent print.

The Cilioscrite, exhibited by Dr. W. E. DIXON and Mr. O. INCHLEY, is a machine to record the movements of cilia and the effect of physical conditions and chemical reagents upon them. The apparatus consists of an upright silver rod free to revolve on its vertical axis. A light aluminium wheel is fixed to the upper end of this and a short ebonite spindle a few centimetres lower, all having the same vertical axis. The ciliated mucous membrane from the frog's pharynx is wrapped round the spindle. Hooks are fixed into the ends of the membrane and connected to a silk thread which passes over a pulley to a weight. The cilia turn the spindle, and a record of their activity is obtained by a time marker recording seconds on a blackened paper attached to the aluminium wheel.

Mr. C. E. S. PHILLIPS showed an Automatic Vacuum Pump of novel construction. The apparatus consists of a modified Toepeler pump, so arranged that it works automatically through the operation of electrically controlled devices, for the purpose of producing extremely high rarefactions. The pump will reduce the gas pressure within a vessel of 200 c.c. capacity from that of the atmosphere to 0.002 m.m. in fifteen minutes. By the action of the mercury in completing the circuit of a relay a solenoid is excited which operates a four-way slide valve, and this, in its turn, connects the lower chamber of the Toepeler pump with either the atmosphere or a mechanical pump, depending upon whether the mercury touches the lower contacts or those in the air trap on the left hand side of the apparatus. Particular attention is drawn to the adjustable device for causing the mercury to pause before ascending into the upper chamber.

Mrs. AYTON showed some striking experiments on the Origin and Growth of Ripple Marks. The experiments illustrate the way in which the sand ripples are formed on the sea shore. If sand be spread quite evenly on the bottom of a trough, and water above the sand be oscillated so as to produce stationary waves, a small ridge is formed where the horizontal velocity of the water is greatest, next a ridge is started on each side of the first, which grows; then two more ridges are started, the former growing, and so on until the whole surface of the sand is ripple-marked. Each ripple now slowly moves towards the place of greatest horizontal velocity, while fresh ripples from near the places of least horizontal velocity. Pairs of ripples then coalesce here and there, and finally the greater part of the sand is assembled in a ripple-marked heap at the places of greatest horizontal velocity, this final result being attained, for example, in about twenty-five minutes in the case of the six foot trough exhibited, when the stationary wave is twice the length of the trough. The vortices which are produced in the lee of each ridge during a part of each swing of the water are shown by means of pepper, and the way in which these vortices build up the ridges is exhibited.

During the evening the following demonstrations were given, with Lantern illustrations:—

Lantern Slides, illustrative of—(1) Operations at the Simplon Tunnel; (2) The Victoria Falls and Gorge of the River Zambesi, and proposed Bridge, by Mr. FRANCIS FOX.

The Charge of Negative Electricity fired off by Radium, by the Hon. R. J. STRUTT.

Colour Photographs of Living Insects, by Mr. F. ENOCK, F.L.S. This last lecturette was of great interest. By no other means than that of colour photography would it be possible to reproduce the natural colours of living insects and their environment. The protective colouration and markings, as well as the natural pose of the insect, are all brought out in a marvellous manner. Insignificant markings, when seen from different points of view, are shown to be of the highest importance for the protection of the insect.

NOTICES OF BOOKS

Radio-activity. By E. RUTHERFORD, D.Sc., F.R.S., F.R.S.C., Macdonald Professor of Physics, McGill University, Montreal. London; C. J. Clay and Sons.

In this book, dedicated to "J. J. Thompson as a tribute of respect and admiration," the author has endeavoured to give a complete account from a physical standpoint of the properties possessed by the naturally radio-active bodies. As our knowledge of radio-activity has been obtained chiefly from information gained by research into the electric properties of gases, this latter subject is rather fully discussed, and a valuable chapter is included giving the various forms of apparatus used, and the methods for the measurement of radio-activity generally in use. The book constitutes a complete summary of the work that has been done upon this very interesting subject, and although some readers may not be prepared to accept at once all the speculations and hypotheses set forth, it is both interesting and valuable to have a clear statement of the grounds upon which have been based some of the most startling conclusions of recent times.

The ionisation theory of gases and the part it has played in furnishing a satisfactory explanation of the passage of electricity through vacuum tubes is discussed in Chapter II., where also the measurement of radio-activity by the determination of the "saturation current" is fully described, as are also C. T. R. Wilson's experiments on the condensation of water upon nuclei, and the use they have been put to by Prof. J. J. Thompson in his recent researches, forming as they do links supporting the series of interesting speculations that are now woven round the phenomena of radio-activity.

In Chapter III., "Methods of Measurement," the action of the rays upon a photographic plate, though valuable as a means of investigating the curvature of the path of the rays where deflected in a magnetic field and similar phenomena, is open to many restrictions as a means of general investigation, and the electric methods for the measurement of the "saturation current" is to be preferred. Various forms of electrosopes are described; one very useful form used by M. and Mme. Curie in their earlier researches is illustrated in full; with this instrument comparative tests of the radio-activity of various materials can be rapidly made, but it is not suited for absolute measurement. A modified form of electroscope has recently been devised by Mr. C. T. R. Wilson that is likely to be very useful. It consists of a small rectangular brass box containing at one of its ends a brass plate insulated and maintained at a constant potential of 200 volts; through the opposite side of the box a wire carrying a very narrow gold-leaf is fixed, insulated by a sulphur bead; normally the gold-leaf is attracted to the charged plate, and the box is tilted to the angle of maximum sensitiveness, about 30°. The other end of the wire carrying the gold-leaf is connected to the insulated system whose rise or fall of potential is to be measured; a movement of 200 scale-divisions was obtained by a rise in potential of only one volt above the case.

The construction and method of using electrometers is very thoroughly set out, and the chapter concludes with a description of M. Curie's quartz piezo-electric, an instru-

ment little known on this side of the Channel, but one that is particularly adapted to the measurement of saturation currents.

Chapter IV. plunges boldly into the nature of the radiations; α -, β -, and γ -rays are each discussed separately in great detail; a description is given of Mr. Strutt's ingenious apparatus for demonstrating that a radium compound acquires a positive charge if contained in an envelope sufficiently thick to absorb the α -rays, but thin enough to allow most of the β -rays to escape, and also an account of Sir William Crookes's spintharoscope for rendering visible the impacts of the α -rays.

Chapters V. and VI., deal with the rate of emission of energy and the properties of radiation; the effect of radium in causing a spark to pass an alternative spark gap and its effect upon selenium are mentioned, as are also its action upon liquids and some of its chemical properties. Several chapters are devoted to the fundamental experiments that make the foundation of the disintegration theory. It is well that the author's views on this important subject have been clearly set out, and this section of the work deserves very careful study by any who may have been startled by the boldness of the views recently propagated. The physiological action of radium rays and their action upon certain microbes is of interest, being fraught with great possibilities. Sir William and Lady Huggins made the discovery that the light from a phosphorescent radium compound in air shows the line spectrum of nitrogen which can be photographed if sufficiently long exposure is given; this shows that radium at ordinary temperatures is able to set up radiations that are otherwise only produced by the electrical discharge under special conditions. Chapter X. deals with the law of decay and recovery of radio-activity in emanating substances; the theory of radio-active change is elaborated on pages 323-331, including the author's diagrams illustrating the course of alteration in uranium, thorium, and radium, and a full account is given of the experiments of Prof. Sir W. Ramsay and Mr. Soddy upon the production of helium from radium and radium emanation.

The book may be truly said to contain all that is known about the radio-active elements, as well as setting out clearly the very interesting though perhaps revolutionary theories that have been devised to account for their remarkable properties, and it is likely for some time to come to be regarded as the standard work upon the subject.

The Extra Pharmacopœia of Martindale and Westcott.

Revised by W. HARRISON MARTINDALE, Ph.D., F.C.S., and W. WYNN WESTCOTT, M.B., D.P.H. Eleventh Edition. London: H. K. Lewis. 1904. Pp. 809.

SINCE the publication of the tenth edition of the "Extra Pharmacopœia" three years ago, William Martindale, the originator of the book, has passed away, and the revision of the work was entrusted to his son, W. Harrison Martindale, and Dr. W. Wynn Westcott.

In this edition many of the older drugs, chemicals, and preparations have been omitted, thus enabling the revisors to add more than three hundred new remedies, drugs, &c. The size and weight of the volume have been decreased, though it contains 112 pages more than the last edition, by using finer paper, without impairing the clearness of the type.

One important addition is the section on Radiology, in which are introduced for the first time notes on radium, Röntgen rays, high-frequency currents, the Finson lamp, and radiant heat in their important applications to therapeutics. Similar fresh monographs appear on amygdala, colchicum, lecitith, ptomaines, &c., and the section on Mineral Waters contains information of about 150 mineral waters in various parts of the world. The water analysis notes and bacteriological notes have been revised and corrected up to date, and notes on the examination of stomach contents appear for the first time. The index has been revised and re-arranged, internal remedies being

printed in Roman type, while those for local or external use are in italics.

Subject-list of Works on Electricity, Magnetism, and Electro-technics in the Library of the Patent Office.
London: Darling and Son, Ltd. 1904. Pp. 286.

THIS subject-list is No. 14 of the Patent Office Library series, and comprises 2374 works, representing 3792 volumes. The catalogue entries relating to these works number 2918, and are distributed under 307 headings and sub-headings. As an example of the system adopted, if a searcher requires information on Electro-plating of gold and silver, for example, the subject of Electro-plating will be found in the general alphabet under that heading. Further information will be obtained by referring to the key in which the headings are shown in class order. Here he will find the headings "Electro-plating," "Electro-deposition," "Electro-chemistry, Technology of," &c., which should next be consulted.

Immune Sera; Hæmolysins, Cytotoxins, and Precipitins.
By Prof. A. WASSERMANN, M.D. Authorised Translation by CHARLES BOLDUAN, M.D. First Edition.
London: Chapman and Hall, Limited. New York: John Wiley and Sons. 1904. Pp. 77.

THE subject of immunity and the reactions which take place when the blood of one animal is injected into the body of another are matters of interest, and are now becoming also of great importance.

At first these experiments, like so many others, were of scientific interest only, but they have been followed up and observed with such minute care that the results have been found applicable to many clinical questions, as well as to certain other problems of every-day life.

In this book we find described in the clearest manner the results of a large number of experiments by which the author hopes to introduce to his readers the essentials of the subject.

The bulk of the experiments herein described have to do with the injection of the blood or serum of one animal into the body of another, and the first important fact noticed in this connection was the following:—That if horses were injected with red blood cells of rabbits, the serum thereafter obtained from the horses would have acquired an appreciable toxicity for rabbits, and it was found further that this toxic action was really a dissolving power acquired by the horse serum for the red corpuscles of the rabbit. From these early observations the author and others have built up what is practically a new branch of biological science, and which is, moreover, leading up to important results bearing on artificial immunity from infectious diseases.

After it had been found that injection of an animal with red blood cells of another animal was followed by the production of definite specific reaction substances, investigators experimented to see whether this was also the case if other animal cells were used, and it was found that a series of reaction substances resulted, entirely analogous to the hæmolysins obtained from the red blood cells; these sera have been called cytotoxins, and are specific for the cells used for injection.

Another class of bodies are called precipitins, and they develop in the serum by treating an animal with albuminous bodies of another animal, and precipitate these albumins when the sera of the two animals are mixed. This power has been found to be very extensive, but it is not entirely specific; for instance, the serum of rabbits injected with chicken serum is a precipitin, not only for chicken serum but also for that of pigeons; while the serum of rabbits treated with that of guinea-pigs is a precipitin also for the serum of monkeys. The author, however, has elaborated a method for distinguishing the albumins from one another, and particularly to distinguish those derived from man from those of other animals. The reaction is

specific except that the serum of an animal treated with human serum reacts also with the serum of monkeys, but not with that of any other animals so far investigated. The book is one of great interest, and we recommend it cordially.

OBITUARY.

THOMAS BAYLEY.

WE regret to announce the death, on June 7th last, from cardiac failure, of Mr. Thomas Bayley.

Mr. Bayley was the compiler of the well-known "Chemists' Pocket-book," by which work he was best known. He was, however, devoted to original research, which he pursued with unflinching ardour in such time as was available to him from his work as a manufacturing and consulting chemist. His work lay chiefly in the domain of the Periodic Law, and he published several papers in the *CHEMICAL NEWS*, *Journal of the Chemical Society*, *Philosophical Magazine*, and *Journal of the American Chemical Society*. Several new and important relations were laid bare in the course of these investigations, especially one deduced graphically from the At. Vol.-At. Wt. diagram. The result is a power of really accurate prediction of the properties of unknown elements, which has been verified in several important cases.

Mr. Bayley was also the author of "A Pocket-book for Pharmacists," and of "The Assay and Analysis of Iron and Steel, Iron Ores, and Fuel"—a work now out of print, but still in demand. H. S. H.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 21, May 24, 1904.

γ -Diphenylanthracene and Symmetric γ -Diphenylanthracene Dihydride.—A. Haller and A. Guyot.—The authors prepare γ -diphenylanthracene in a pure state, and various derivatives of this body.

Direct Hydrogenation of Homologues of Aniline.—Paul Sabatier and J. B. Senderens.—For the amines of the first group (methyl- or ethylanilines) hydrogenation can be effected by means of nickel between 160° and 180°, and takes place quite regularly. The production of condensed amines, which takes place in the case of aniline, is impossible for the tertiary amines. The only secondary reaction being the production of a little formic amine and benzene, transformed itself into cyclohexane. Ethylaniline, $C_6H_5NHC_2H_5$, gives cyclohexylethylamine, $C_6H_{11}NHC_2H_5$; Diethylaniline, $C_6H_5N(C_2H_5)_2$, giving cyclohexyldiethylamine, $C_6H_{11}N(C_2H_5)_2$; and dimethylaniline, $C_6H_5N(CH_3)_2$, giving cyclohexyldimethylaniline, $C_6H_{11}N(CH_3)_2$.

Thermic Ionisation of Saline Vapours.—G. Moreau.—When saline vapours are raised to a high temperature—say, 1000°—they become conductors, and remain conducting down to ordinary temperatures. The conductivity depends on the nature of the salt and its chemical constitution. The author's experiments on this subject show—
(1) For a solution of constant concentration of a salt, A, the current, i , at first proportional to the voltage of the current, tends towards a limit, I , when this increases; (2) for the same salt the current limit I is proportional to

the concentration of the solution if this is very dilute (1 gm. per 1000), and varies more slowly; it tends towards a limit, J , attained more rapidly the less conducting the vapour; (3) of all the salts examined, those of potassium are more conducting than others, and their conductivity limit, I , depends on the radical acid; KI , KCl , KBr , and KNO_3 are three or four times more conducting than the other potassium salts; (4) for the same salt, A , the conductivity is only apparent if the porcelain tube is incandescent, and this increases rapidly with the temperature.

Cryoscopic Examination of Solutions in Antimony Sulphide.—MM. Guinchant and Chretien.—The authors investigate the subject of cryoscopy at very high temperatures. By the use of thermo-electric couples, the temperature of the medium can be accurately determined. The experiments were made with silver sulphide, values being obtained for the weight of this sulphide dissolved in 100 grms. of antimony sulphide, and for the lowering of the solidification-point of antimony sulphide in consequence. Experiments were also made with lead, nickel, and antimony sulphide.

Estimation of Atmospheric Formaldehyde.—H. Henriet.—The author describes the experiment by which he estimates the amount of formaldehyde in atmospheric air. The proportion he ascertains to be from 1/100,000 to 5/100,000 of the weight of the air.

Method of Identifying the Fatty Acids.—René Locquin.—M. Bouveault a short time ago described a method of identifying alcohols by preparing their pyruvic ethers and combining these with semicarbazide. Crystalline compounds are thus easily obtained. The author evolves a similar method of identifying the fatty acids. All these acids form with acetol or oxyacetone, $CH_3-CO-CH_2OH$, ketonic ethers susceptible of giving also semicarbazones, which constitute the characteristic derivatives of the acids to which they correspond. He proves that the semicarbazones thus obtained easily crystallise, are easy to purify, and have very defined fusing-points.

Transformation of Azoic Compounds with Ortho-substituted Alcohol Function into Indazolic Derivatives.—P. Freundler.—The author showed that benzene- α - α -benzyl alcohol yields phenylindazole when it is distilled or heated at 100° with dilute sulphuric acid. This reaction is absolutely general, and is effected each time that the azoic group is situated in the ortho-position with respect to a CH_2OH function:—

Limit of the Union of Diazobenzene and Phenol.—Leo Vignon.—By the direct action of one molecule of diazobenzene chloride on one molecule of phenol the author obtains paraoxyazobenzene. Two molecules of diazobenzene chloride acting on one molecule of phenol give an almost theoretical yield of phenolbisdiazobenzene. The formation of this latter body represents the limit of the union. In no case has phenoltridiazobenzene been obtained.

MISCELLANEOUS.

Action of Peroxide of Nitrogen on the Isonitrosomalonic Ethers.—L. Bouveault and A. Wahl.—If peroxide of nitrogen in excess is made to act on 50 grms. of isonitrosomalonic acid ethyl cooled in ice, at first the peroxide is dissolved, with the production of a brownish green colouration. In a short time bubbles of gas are formed throughout the mass. The temperature must be kept down, and after an hour or two the reaction is complete

and the liquid is decolorised. The product is then submitted to fractional distillation *in vacuo*, and two principal fractions are obtained; one boiling at $95-110^\circ$ under 12 to 15 m.m., the other at $110-130^\circ$. The aqueous solution of the first one gives crystals of hydrate of mesoxalate of ethyl. The second fraction is treated with ammoniacal water, and the yellow solution shaken up with ether, decanted, and decomposed with a dilute acid. The precipitated oil is purified and dissolved in absolute alcohol, and an excess of ammoniacal alcohol added. After some time a salt is deposited; this is re-crystallised in alcohol, when yellow flakes are formed, consisting of the ammoniacal salt of the nitromalonate of ethyl.—*Bull. Soc. Chim., Series 3, XXIX., Nos. 18-19.*

Production of Pure Iodine, and the Preparation of Titrated Solutions of Iodine and Sodid Hyposulphite.—L. de Koninck.—The author reviews the different known methods for procuring pure iodine for the preparation of titrated solutions. He recommends the action, by the dry way, of bichromate of potassium on iodide of potassium, feeling assured that the impurities usually contained in these two salts are generally without influence on the final product; further, it is very easy to purify these salts. The iodine is prepared by this method, by heating a very intimate mixture of one part of iodide with three-fourths of bichromate. By collecting the iodine in a tared matras or glass bulb, it is possible to prepare a titrated solution directly and rapidly.—*Bull. Assoc. Belge Chim., vol. xvii., p. 15.*

Electrolytic Estimation of Thallium (Anodic Precipitation of the Oxide).—E. Haberg.—Excellent results can be obtained by electrolysis a sulphuric solution of thallium; 0.2 to 1 gm. of the sulphate are dissolved in a platinum crucible in 80 to 100 c.c. of water; add 2 to 6 c.c. of normal sulphuric acid and 5 to 10 c.c. of acetone, electrolyse with a current varying from 1.7 to 0.3 volts at the end of the operation. The platinum crucible serves as the anode; the cathode is formed of a disc of platinum. The intensity of the current should not be more than 0.02 to 0.05 amperes at the outside; the temperature should be maintained between 50 and 55° ; the volume of the liquid should remain constant. The precipitated oxide is washed in water, twice with alcohol, once with ether, and dried for twenty minutes at $160-165^\circ$. The addition of an alkaline sulphate facilitates the electrolysis by increasing the conductivity of the solution, but in this case we must carefully wash the precipitated oxide or else we should obtain too high a figure.—*Zeit. Anorg. Chem., vol. xxxv., p. 347.*

A New Method for the Estimation of Selenium.—A. Gutbier and E. Rohn.—The authors have applied to the estimation of selenium, the method mentioned by one of them for the estimation of tellurium (*Zeit. Anorg. Chem., vol. xxxii., p. 295*). The selenium should be in the form of selenious acid, for, contrary to what has been observed with tellurium, the aqueous solutions of selenic acid are only slowly and incompletely reduced by hypophosphorous acid. In the presence of concentrated hydrochloric acid we obtain only a small quantity on selenium dissolved in the colloidal state, without any precipitate being observed. The aqueous solutions of selenious acid are precipitated slowly in the cold, and rapidly when heated. The selenium obtained is quite comparable with the tellurium produced under the same conditions. By prolonging the heating the reduction goes as far as seleniuretted hydrogen. For the quantitative determination of selenium the operations should be carried out in alkaline solution. Instead of 71.19 of selenium the authors found 71.22, 70.99, 71.08, and 71.25.—*Zeit. Anorg. Chem., vol. xxxiv., p. 448.*

The Estimation of Iron in the presence of Zirconium, by Rivot's Method.—K. Daniel and H. Leberle.—Rivot's method for the separation of two oxides of which one only is reducible by hydrogen, does not apply to the separation of oxide of iron and zirconium. The reduction of the iron only takes place in anything like a complete

manner in the presence of a very small quantity of ZrO_2 . With 1 equivalent of Zr for 50 of iron, the figure found for the iron is 0.1822 instead of 0.1830. The error increases rapidly with the percentage of zirconium. In a mixture of equal parts of iron and zirconium, the authors found 0.0882 of iron instead of 0.0933. In the experiments of Gutbier and Hüller, who recently described this method (*Zeit. Anorg. Chem.*, vol. xxiii., p. 92), and appeared to have arrived at very concordant results, the figures found are a consequence of the incomplete drying of the oxides employed. The authors have, in fact, made certain that the oxides of iron and of zirconium dried at 105° , as in these last-named chemists' experiments, retain notable quantities of water. The loss of weight observed results, therefore, from (1) the actual reduction of a portion of Fe_2O_3 , and (2), from the dehydration of the hydrated oxides ($Fe_2O_3 \cdot xH_2O$).—*Zeit. Anorg. Chem.*, vol. xxxiv., p. 393.

NOTES AND QUERIES.

BOROUGH OF SWANSEA TECHNICAL COLLEGE.

LECTURER IN METALLURGY.

Applications are invited for the above Lectureship. Salary £200 per annum, rising by annual increments of £10 to £250.

The Lecturer will be expected to enter upon his duties in September. Applications, with one set of copies of testimonials, should reach the undersigned not later than THURSDAY, JUNE 30th.

Further particulars can be obtained from the SECRETARY at the College.

J. TREVOR OWEN, M.A., Principal.

UNIVERSITY COLLEGE of WALES, ABERYSTWYTH.

ASSISTANT LECTURER AND DEMONSTRATOR IN
CHEMISTRY.

The Council invite applications for the Post of ASSISTANT LECTURER and SENIOR DEMONSTRATOR in CHEMISTRY.

Applications, with copies of testimonials, should reach the undersigned, from whom further particulars may be obtained, not later than SATURDAY, JULY 9, 1904.

T. MORTIMER GREEN, Registrar.

June, 1904

UNIVERSITY OF BIRMINGHAM.

The Council invites applications for the following Appointments:—

ASSISTANT LECTURER in MATHEMATICS.

ASSISTANT LECTURER and DEMONSTRATOR in PHYSICS.

ASSISTANT LECTURER and DEMONSTRATOR in CHEMISTRY.

The stipend in each case will be £150 per annum.

The Candidates selected will be required to enter on their duties on October 3rd next.

Further particulars may be obtained from the undersigned, to whom Applications, accompanied by six copies of testimonials, should be sent not later than AUGUST 1st, 1904.

GEO. H. MORLEY, Secretary.

EDINBURGH AND EAST OF SCOTLAND COLLEGE OF AGRICULTURE.

AGRICULTURAL CHEMISTRY.

The Governors of the College will proceed at an early date to the Appointment of a Lecturer on the above subject.—Applications, accompanied by 45 copies of testimonials, should be addressed, not later than JULY 30th, to the SECRETARY, 13, George Square, Edinburgh, from whom further particulars may be obtained.

No. 2327.—JULY 1, 1904.

ON THE ACTION OF RADIIUM EMANATIONS ON DIAMOND.*

By Sir WILLIAM CROOKES, F.R.S.

WHEN diamonds are exposed to the impact of radiant matter in a high vacuum they phosphoresce of different hues, and assume a dark colour, becoming almost black when the bombardment is long continued (*Phil. Trans.*, 1879, Part II., p. 658, par. 625).

Some diamonds blacken in the course of a few minutes, while others require an hour or more to discolour.† This blackening is only superficial, and although no ordinary means of cleaning will remove the discolouration, it goes at once when the stone is polished with diamond powder. The fact that the black stain is not affected by ordinary oxidising reagents would seem to show that it is not due to a layer of amorphous carbon; but it might be graphite, which is much more resistant to oxidation. Becquerel has shown that graphite is converted into graphitic oxide by long digestion in a warm mixture of potassium chlorate and strong nitric acid, while diamond—even in a very finely powdered state—is absolutely unaffected by the mixture (*Ann. de Chim. et de Phys.*, [4], xix., p. 392).

Some forms of graphite dissolve in strong nitric acid; others require a mixture of highly concentrated nitric and potassium chlorate to dissolve them, and even with this intense oxidising agent some graphites resist longer than others. M. Moissan has shown that the power of resistance to nitric acid and potassium chlorate is in proportion to the temperature at which the graphite has been formed, and with reasonable certainty we can estimate this temperature by the resistance of the graphite to this reagent.

Judging from the long time required to remove the superficial darkening from diamond, the graphite is as resistant as that formed at the temperature of the electric arc.

On one occasion when I had blackened the surfaces of diamonds by molecular bombardment *in vacuo* M. Moissan was present, and took some away with him for further examination. He subsequently reported the results in the *Comptes Rendus* (vol. cxiv., No. 13). He heated the diamond to 60° in an oxidising mixture of potassium chlorate and fuming nitric acid prepared from monohydrated sulphuric acid and potassium nitrate fused and quite free from moisture. The action on the black layer is very slow. There is produced graphitic oxide, which at an increased temperature yields pyrographitic acid, easily destroyed by nitric acid. Hence the variety of carbon

which coated the diamond was graphite. The transformation of diamond into graphite requires the high temperature of the electric arc. The higher the temperature to which graphite is raised the greater is its resistance to oxidation. M. Moissan concludes that the temperature reached by the surface of the diamond in my radiant matter tubes is probably about 3600°.

The β -rays from radium having like properties to the cathode stream in a radiant matter tube, it was of interest to ascertain if they would exert a like influence on diamond. Two Bingara diamonds, A and B, weighing respectively 0.960 and 1.020 grains, were selected as near as the eye could judge of the same size and colour—very pale yellow, technically known as "off colour." Diamond A was put in a drawer far removed from radium or any radio-active body. Diamond B was kept close to a quartz tube containing about 15 m.-grms. of pure radium bromide sealed *in vacuo*. It phosphoresced brightly and continued to glow the whole time of the experiment.

After a fortnight the two diamonds were put side by side and compared. I could see no appreciable difference in colour between them. Diamond B was now replaced close to the quartz tube of radium, and they were kept in contact for six weeks. At the end of that time examination again showed scarcely any difference between the two. The one which had been near the radium might be a little the darker of the two, but the difference was too slight to enable me to speak positively.

Diamond B was now put inside a tube with radium bromide, the salt touching it on all sides, as it was thought possible that a screen of quartz might interfere with the passage of emanations which would act on the diamond. The comparison diamond was kept removed from the emanations as before. The experiment was continued for seventy-eight days, when the two diamonds were again examined. There was now a decided difference in colour between them; diamond A was of its original pale yellow "off colour," and diamond B was of a darker appearance and of a bluish green tint, with no yellow colour apparent.

It thus appears that the property which radium emanations possess of darkening transparent bodies which they impinge upon—a property very marked in the case of glass, and less with quartz—also holds good in the case of diamond.

Diamond B was now heated to 50° C. in a mixture of strongest nitric acid and potassium chlorate for ten days, the mixture being renewed each day. At the end of this time the diamond had lost its dull surface colour, and was as bright and transparent as the other stone, but its tint had changed from yellow to a pale blue-green.

The radium emanations have therefore a double action on the diamond. The β -rays (electrons) effect a superficial darkening, converting the surface into graphite in a manner similar to, but less strongly than, the more intense electrons in the cathode stream. But the alteration of the body

* A Paper read before the Royal Society, June 16th, 1904.

† At a lecture before the Royal Institution on June 11, 1897, I exposed a flat macule crystal of diamond to radiant matter bombardment before the audience for about five minutes, a strip of metal covering part of the stone. On removing the diamond from the vacuum tube and projecting its image on the screen with the electric lantern, the image of the darkening was very apparent.

colour of the stone by emanations which are obstructed by the thinnest film of solid matter, even by a piece of thin paper, is not so easy to understand. A superficial action might be expected, but not one penetrating through the whole thickness of the diamond. I believe the alteration of colour is a secondary effect; in presence of radium the diamond is extremely phosphorescent, and it continues to shine during the whole time of the experiment. This constant state of vibration in which the diamond was kept for many weeks may have caused an internal change revealing itself in a change of colour. Indeed, it is not difficult to suppose that a chemical as well as a physical action may result. If the yellow colour is due to iron in the ferric state a reduction to the ferrous state would quite account for the change of colour to a pale blue-green.

This alteration of colour may be of commercial importance. If "off colour" stones can be lightened their value will increase, while if the prolonged action of radium is to communicate to them a decided colour they would be worth much more as "fancy" stones.

[Added June 16, 1904.—After the ten days' heating in the above acid mixture the two diamonds were put together in a glass tube and carried about for twenty-five days, sometimes loose and sometimes in the tube. They were then laid near together on a sensitive film in total darkness for twenty-four hours. On developing, diamond B had impressed a strong image on the film, but only a very faint mark could be seen where the other diamond had been.

The experiment was then repeated for confirmation, allowing the diamonds to remain in contact with the sensitive surface for only five hours. On development, a good image of diamond B was seen, but not so black as in the former case.

The fact that diamond B was strongly radio-active after it had been away from the radium for thirty-five days—for ten of which it was being heated in a mixture powerful enough to dissolve off its outer skin of graphite—seems to me proof that radio-activity is by no means a simple phenomenon. It not merely consists in the adhesion of electrons or emanations given off by radium to the surface of an adjacent body, but the property is one involving deep-seated layers below the surface, and, like the alteration of tint, is probably closely connected with the intense phosphorescence the stone had been experiencing during its seventy-eight days' burial in radium bromide].

The British Journal of Photography.—The proprietors of this valuable journal have recently published a "Jubilee Number" to mark the fiftieth year of its publication, though it has not always been known by the title it now bears. It was first started on January the 14th, 1854, as the *Liverpool Photographic Journal*, and after going through many evolutionary changes it assumed its permanent title of *The British Journal of Photography* on January 1st, 1860, at which time it was in the able hands of Mr. Henry Greenwood, who retained control until his death in 1884. This "Jubilee Number" contains thirty special articles on the most popular and prominent phases of modern photography, written by competent specialists, besides an illustrated history of the journal since its foundation. In this history we find a list of the editors, among whom are many well-known men who have since made their mark in the world of science. Among these we may mention James Alexander Forrest, 1854-1856; George Shadbolt, 1857-1864; George Dawson, Samuel Highley, Sir William Crookes, James Martin, John Traill Taylor, W. R. Bolton, and last but not least, Thomas Bedding, who at present fills the editorial chair in such an able manner. Such an event as the publication of this "Jubilee Number" is unique in the annals of photography, and marks an important epoch in the science. We heartily congratulate our contemporary on the success it has already achieved, and trust that it will continue to flourish in the future as it has done in the past.

TECHNICAL RESEARCH AND THE COLLEGE SYSTEM.

II.

By W. P. DREAPER, F.I.C., &c.

IN connection with my recent proposals for a systematic scheme of technical research in our scientific colleges, the question naturally presents itself, Is the training given to the students of such a nature that it will enable them to undertake the experimental work necessary for such a scheme in an intelligent way? If they are not capable of entering in their last year upon any suggested research, then it follows that they are equally incapable of entering the industrial world as anything more than routine men.

Some time ago, Prof. H. E. Armstrong complained rather bitterly that the material sent up from the schools was of an inferior nature, and that this was a very serious difficulty in the way of technical training. No one outside the schoolmaster circle will seriously deny the truth of this statement. There can be no doubt that the students sent up from the schools are seriously deficient in the power of thinking for themselves. As possible curates their qualifications may be supreme. As thinkers and workers combined their preliminary training is, as has been stated, a national scandal and in itself enough to throw doubt upon our whole scholastic system with its pedantry and empiricism.

Important as this question may be, I only wish to mention it in passing as playing some part in the subject before us. My object is to draw attention to the importance of giving a more human element to the teaching of the exact sciences by connecting the facts with the processes by which they were established, and these in their turn with the men who worked them out; for is not the ultimate place for the technical student in the experiment world? He must be trained on such lines that he will first of all be taught to think for himself. In order that this may be the prime idea in his educational course, it is contended that the whole character of his training should be more personal in its nature than it is to-day.

If the text-books of to-day are examined it will be found in the majority of cases that they are calculated to fill the student's mind with a set of relatively immaterial facts. There seems to be a tendency in the more advanced ones, perhaps on account of examination requirements, to stuff them with secondary matter which properly belongs to some standard book of reference, and to lose sight of the importance of keeping main ideas absolutely to the front as connecting chains of thought.

The modern text-book tends to become more diffused in its nature. The authors seem unable to carry the burden of their accumulated facts with interest to themselves or instruction to their readers. This is unfortunately liable to stereotype the course of a college by limiting it to the lines and ideas of a certain collector of facts, be he one of the college staff or not.

The whole routine of the college should within necessary limits be of as personal nature as possible, in order that the student may feel—may I say it?—at home in his work, or rather in the work of the greatest experimenters of the age.

May I give a very simple instance of what I mean, taking the preparation of oxygen as an example? Here Priestley's name and influence should reign supreme. The lecture should start with an account of his experience with the then unknown. Step by step his work should be followed from the personal side as well as the experimental. The influence of the man experimenting should be present. His actions, which will be of a similar nature to those of the student in his subsequent life's work, should occupy a prominent position in the record-impression on the student's mind.

It is surely not too much to say that all the knowledge which is available is of this personal nature. Here a touch from one hand, and there a gentle moulding from another.

Systems and lines of thought must have their day. They will merge into the light of our more extended experience, but a student's knowledge will never become useless or quite out of date if it is based on the personal experience of those men who have contributed their quota to the discoveries of the age. It will be easier for the worker to change his ideas, if needs be, if his mind is imbued by the processes by which those ideas were formed; with the enthusiasm this will create, he will be better able to keep abreast of the times.

After all, our knowledge is nothing more than the collected experience of those who have stepped in advance of the crowd. Our knowledge is so strictly personal that it may not extend outside ourselves. It may be ridiculously trivial when compared with the absolute. Be this as it may, the personal side of the question is sacred to the memory of those who have extended our lines of thought, and the students of to-day will be the better workers of to-morrow if this side is uppermost instead of being suppressed under a load of bare facts.

This training would surround the student, even in his early days, with an influence that would lead him to wish to do something more than mix solutions in a test-tube. He would somehow get hold of the idea that here Priestley stepped in, did so and so, and obtained such a result; or at this point Darwin suffused the whole of biology with his thought. Evolution is one of the few cases where perhaps the influence of the man is supreme. To this may be attributed the extraordinary advance in this subject since the publication of his work; or we may at least divide it equally with the attraction of the subject itself.

When the student reaches his "work period" with thoughts like these, he will drive through many difficulties. Is it too much to say that the nation that first learns this lesson will be the nation to lead? The suppression of the personal in science is not an advantage, it is a serious defect.

To pass on to the professor's influence. In the majority of cases this is of too impersonal a nature. The students freeze in the light of a Polar star. Many English students know as little about their professors as a lay reader about his bishop. This should not be. The old cry for "facts" must give way to the more important cry of "personality."

It is clear from the confession of its students that that wonderful school of which Liebig was the master derived a great deal of its power from the personality of its leader. Yet many of our professors never indicate by word or deed that they have ever been students, any more than a certain famous minister in fiction ever indicated in the pulpit that he had lived. Yet every student's eye is rivetted on his instructor, but in many cases the latter has burnt his boats behind him, and the students stand on the other side of the water. A well-known manufacturer and chemist recently said at Burlington House, "Save us from the professors," but the student's only wish is to know what kind of a man he really is and the secret of his success.

Yet all the social considerations are against this in this country, and it seems to be an unwritten law that a lecturer shall say as little as possible about his own work at the lecture table.

In after years our thoughts undoubtedly turn more from the personal to either facts or things. If to the former, our life's work is already nearly over.

This great personal influence, important as it is, is lost sight of in many of our scientific colleges and departments, but it is this factor that will enable students to obtain the "hang" of any research they may have to take part in under any such scheme as I outlined in my previous article.

In order that the future workers may have the power to grapple with the problems before them, they must be acquainted with the difficulties and successes of others, working as they must work. This side of their training is often conspicuous by its absence. The successes of the past are crystallised to-day into dry facts; the difficulties not considered. How then shall the young workers meet

their own difficulties, and not be discouraged? For out of the difficulties of the technical worker must chiefly spring his original work; and the student of to-day is the technical worker of to-morrow. With him may rest the future of our industrial position.

ON THE CHARACTERISATION OF LEAD:

AN ANSWER TO HERR CLEMENS WINKLER.

By K. A. HOIMANN.

In the article (*Berichte*, 1904, xxxvii., 1657) on "Radio-activity and Matter," which has recently appeared, Herr Clemens Winkler casts doubts on the accuracy of the equivalent weight determinations which I performed with the active lead sulphate obtained from pitchblende, because my preparations were dried only at 400° to 420°, and "experience has proved that at such a low temperature it is not possible" to expel completely the free sulphuric acid which adheres to it, so that thus the strikingly high percentage of sulphuric acid (41.35 per cent instead of 31.71 per cent for ordinary lead sulphate), which I found, cannot forthwith be accepted as indicating the presence of a metal of lower equivalent weight. In answer to this I should like to say that, according to my control experiments previously performed, pure ordinary lead nitrate on evaporation with a moderate excess of pure sulphuric acid, even at about 300°, gives the theoretical quantity of sulphate, and thus retains no free acid, but is of the normal composition. But because the objection mentioned above was raised by a chemist who is an authority in the region of analytical chemistry, and because the point in question is of the greatest importance for the gravimetric determination of lead, I repeated my experiments, and thus confirmed my earlier results.

I used lead nitrate which was prepared from electrolytically separated lead dioxide, and had been purified by repeated re-crystallisation.

The separate specimens were dried *in vacuo* (cf. Leo Backeland, *Fourm. Amer. Chem. Soc.*, xxvi., 391), and after heating to 100° for one hour their weight was constant. They were then dissolved in water, and converted into sulphate by evaporation with a moderate excess of pure dilute sulphuric acid at 270°, and the sulphate was heated (1) for 1.5 hours at 320°, (2) then for five hours at 355°, (3) then for 1.5 hours at 390°, and (4) for ten minutes at incipient red heat.

- i. 0.2564 grm. nitrate should theoretically* give 0.2347 grm. sulphate. The weighings gave—(1) 0.2349, (2) 0.2346, (3) 0.2344, (4) 0.2346 grm. sulphate.
- ii. 0.5556 grm. nitrate should theoretically give 0.5086 grm. sulphate. The weighings gave—(1) 0.5091, (2) 0.5085, (3) 0.5084, (4) 0.5087 grm. sulphate.
- iii. 0.2655 grm. nitrate should theoretically give 0.2430 grm. sulphate. The weighings gave—(1) 0.2433, (2) 0.2432, (3) 0.2431, (4) 0.2431 grm. sulphate.
- iv. 0.1926 grm. nitrate should theoretically give 0.1763 grm. sulphate. The weighings gave—(1) 0.1768, (2) 0.1760, (3) 0.1758, (4) 0.1762 grm. sulphate.

Hence it follows that on evaporation of pure lead nitrate with excess of sulphuric acid, even at temperatures below 400°, it is completely converted into normal sulphate. Thus the excess of sulphuric acid found according to my analysis in the radio-lead sulphate dried at 400° to 420° cannot be due to adhering free acid, but proves the presence of a substance different from ordinary lead, and I hope shortly to report definitely on its qualitative and quantitative behaviour.—*Berichte*, 1904, xxxvii., 2197.

* O=16 according to the International Atomic Weight Table

THE
DECOMPOSITION OF THE ALKALINE-EARTHY
CARBONATES BY CHLORIDE OF
AMMONIUM IN THE PRESENCE OF WATER.

By H. CANTONI and G. GOGUELIA.

A. *Action of Chloride of Ammonium on Carbonate of Barium in the presence of Water at Boiling-point.*

WHEN we add powdered carbonate of barium to a solution of chloride of ammonium of medium concentration, and heat to boiling for a certain time, a part or the whole of the carbonate of barium—according to the conditions under which the operation is carried out—passes into solution in the state of chloride of barium.

The filtered solution, which should contain only chloride of barium, and, according to H. Schreib, carbonate of ammonium, does not become cloudy on cooling. Further, we have not detected any traces of fixed carbonic anhydride. All the carbonic acid escapes according to the following equations:—

To make quite certain that the whole of the carbonic acid displaced from the carbonate of barium escapes, and does not unite with the ammonia in any proportion, we have estimated the CO_2 given off during the decomposition.

The carbonic acid found corresponds exactly with the amount of carbonate of barium passing into the state of soluble chloride.

The flask in which the double decomposition was made is fitted with a vertical condenser, so that the concentration of the solution of chloride of ammonium may be constant during the whole time of the operation. At the top of the condenser is fixed a washing bulb containing sulphuric acid. Following this bulb, which serves to retain the ammonia, are U-tubes containing chloride of calcium to dry the gas. Finally, a Liebig potash tube containing a solution of caustic potash (1 part of KOH, 2 parts of water) serves to retain quantitatively the carbonic anhydride.

A current of air, previously freed from its carbonic acid, circulates through the apparatus and drives all the CO_2 into the tube arranged for its estimation.

We have made several trials to determine the conditions of this decomposition by varying both the time of boiling and the concentration of the solution of chloride of ammonium.

H. Schreib, in a paper published in 1889, determined the decomposition of carbonate of lime by chloride of ammonium, but these experiments were not carried out on solutions of varying concentrations of NH_4Cl .

By taking $\frac{1}{10}$ th of a gram-molecule of carbonate of barium, and $\frac{2}{5}$ th of a gram-molecule of chloride of ammonium dissolved in 500 c.c. of water, and heating to boiling for one hour thirty minutes, we obtained from several gravimetric estimations of the filtered solution 1.5455 grms. of carbonate of barium which had passed into the state of soluble chloride.

It will be seen that instead of having the quantity of carbonate of barium solubilised, corresponding to the chloride of ammonium used, we have only $\frac{1}{10}$ th.

We have repeated this experiment under the same conditions, but increasing the time of boiling. When boiled for twenty-four hours the amount of BaCO_3 decomposed was 2.1375 grms.; that is, $\frac{3}{10}$ ths of the amount equivalent to the chloride of ammonium used.

In another experiment, we heated to boiling for forty-eight hours, and we found 2.4732 grms. of BaCO_3 decomposed; that is, half the amount of carbonate of barium corresponding to that of the chloride of ammonium used.

In another series of experiments we increased successively the concentration of the solution of chloride of ammonium. With 42.8 grms. of NH_4Cl , or sixteen times the amount

previously used, and after heating to boiling for one hour thirty minutes, 7.946 grms. of BaCO_3 were decomposed. The constant quantity of carbonate of barium in these two series of experiments was 9.87 grms.

B. *Determination of the Time necessary for the complete Decomposition of the Carbonate of Barium.*

To get an estimate of the time necessary for the complete transformation of the carbonate into chloride by the prolonged action of chloride of ammonium in the presence of water, and at boiling temperature, we made two series of experiments; one with different quantities of chloride of ammonium in a constant quantity of water in the presence of an invariable weight of carbonate of barium, and at boiling temperature; the other with 1 gram-molecule of BaCO_3 and twice the amount of NH_4Cl in 500 c.c. of water, boiling for different times. We give the results of these different experiments.

When we heat powdered carbonate of barium to boiling with a solution of chloride of ammonium of known strength for a given time in a round bottomed flask of Jena glass of 100 c.c. capacity, fitted with a vertical condenser, all the carbonate of barium present is decomposed, and changed into the state of chloride of barium. The liquid in the flask has a milky appearance at the commencement of the operation on account of the presence of the insoluble carbonate of barium; it becomes perfectly limpid, and does not contain a trace of BaCO_3 after having been boiled for a suitable time.

197.4 grms. of chloride of ammonium in 500 c.c. of water decomposed 9.87 grms. of carbonate of barium almost instantly; at the moment of boiling the liquor became perfectly limpid.

With the molecular weight of NH_4Cl , that is 53.5 grms. in 500 c.c. of water, three quarters of an hour were required to decompose 9.87 grms. of barium.

We were obliged to heat for sixteen hours to decompose 9.87 grms. of BaCO_3 with a solution of 21.4 grms. of NH_4Cl in 500 c.c. of water. These figures suffice to show how BaCO_3 is decomposed by solutions of NH_4Cl at boiling temperature. All these experiments were made with the same carbonate of barium, pulverised to the same grade. H. Schreib has shown distinctly the different actions of chloride of ammonium on the different carbonates of lime, and also the importance the state of the carbonate used has on these determinations.

C. *Action of Chloride of Ammonium on the Carbonates of Barium, Calcium, and Strontium in the presence of Water at the ordinary Temperature.*

Carbonate of Barium.—When we add powdered carbonate of barium to a solution of chloride of ammonium of medium strength at the ordinary temperature, we observe that after a fairly long time a portion of the carbonate of barium is decomposed.

We have made several experiments at the ordinary temperature during a similar time, but with solutions of chloride of ammonium of different mean strengths.

When we used a solution of 1 gram-molecule strength of chloride of ammonium, that is 53.5 grms. in 1000 c.c. of water, and an excess of powdered carbonate of barium, and kept it for ninety-eight days at the ordinary temperature, say 15°, 0.919325 gram. of BaCO_3 was decomposed.

When operating under exactly the same conditions as regards time and temperature, but with a 10 per cent solution of chloride of ammonium, 1.255651 grms. of BaCO_3 were decomposed.

We found that 1.5 grms. of BaCO_3 were decomposed when operating in the same way, but with a solution of chloride of ammonium containing 200 grms. of NH_4Cl per litre; that is 20 per cent.

Carbonate of Calcium.—The results obtained with carbonate of calcium are different from those obtained with carbonate of barium; they are much lower.

By operating with a 5.35 per cent solution of NH_4Cl for

ninety-eight days at the ordinary temperature (15°) in the presence of an excess of CaCO_3 , 0.42252 grm. was transferred to CaCl_2 .

With a 10 per cent solution of chloride of ammonium, we obtained 0.60144 grm. and 0.6480 grm. with a 20 per cent solution, the time and temperature being constant.

Carbonate of Strontium.—Of the three alkaline earthy carbonates, carbonate of strontium is the most difficult to decompose by means of aqueous solutions of chloride of ammonium.

After leaving a 5.35 per cent solution of NH_4Cl for ninety-eight days in the presence of an excess of carbonate of strontium at the ordinary temperature (15°), 0.17944 grm. of the carbonate was decomposed.

By working under exactly the same conditions, but with a 10 per cent solution of chloride of ammonium, 0.25936 grm. was decomposed.

With a 20 per cent solution of chloride of ammonium, we found 0.35808 grm. of SrCO_3 was decomposed.

All the experiments at the ordinary temperature were carried out in specially made hermetically sealed vessels. The temperature was kept constant within the closest limits possible for ninety-eight days.

In the following table we give the results obtained in the cold with the different carbonates so that they may be compared easily.

Table showing the Decomposition of the Alkaline-earthly Carbonates by Cold Aqueous Solutions of NH_4Cl .

Per cent of NH_4Cl solution.	Temperature.	Time in days.	Grams. of carbonate decomposed.		
			BaCO_3 .	CaCO_3 .	SrCO_3 .
5.35	15°	98	0.91745	0.42252	0.17944
5.35	15°	98	0.92120	0.42436	0.17830
10	15°	98	1.255122	0.60144	0.25936
10	15°	98	1.256180	0.61732	0.2606
20	15°	98	1.50000	0.64800	0.35808
20	15°	98	1.49640	0.64320	0.35890

The above experiments lasted from January 27 to May 4, 1903.

In his paper in 1889, H. Schreib declared that carbonate of lime was not decomposed by chloride of ammonium in cold aqueous solution. Doubtless he did not prolong his experiments sufficiently, as we see that with a 20 per cent solution of NH_4Cl , for example, we have 0.648 grm. of CaCO_3 decomposed. (An excess of CaCO_3 in 1 litre of a 20 per cent solution of NH_4Cl at 15° for ninety-eight days).

Our experiments show further the difficulty there is to free the alkalis from the alkaline-earthly metals in the analysis of silicates. (Estimation of the alkalis). After having decomposed the silicate by HFl and H_2SO_4 , we precipitate the sulphuric acid with BaCl_2 , then treat with NH_3 to precipitate the iron, alumina, and part of the magnesia; then with carbonate of ammonium we precipitate the lime from the silicate and the excess of BaCl_2 . Now we have BaCO_3 , CaCO_3 , NH_4Cl , KCl , and NaCl left; by slightly raising the temperature a large part of the carbonates are made soluble. It is for this reason that great care and several successive calcinations are needed to free the alkalis from the alkaline-earthly metals.

The attack of these different carbonates by the alkaline chlorides leads us to expect that this phenomenon of decomposition ought to be repeated with the oxalates, phosphates, sulphates, &c., of the alkaline earths.

Finally, it may be observed that the attack of carbonate of strontium by chloride of ammonium, and probably by other salts as well, causes the estimation of strontium as carbonate to be inexact, except under exceptional circumstances; therefore, when we have to estimate the alkaline-earthly metals in a solution containing saline substances, and especially alkaline chlorides, it would be more prudent to adopt a volumetric method, or some indirect process.—*Bull. Soc. Chim., Series 3, vol. xxxi., No. 6.*

ON ALUMINIUM POWDER AND THE OXIDATION OF ALUMINIUM.

By E. KOHN-ABREST.

ALUMINIUM does not seem to have been studied sufficiently up to the present time from the point of view of its chemical affinities.

It is certain that under ordinary circumstances pure aluminium does not undergo any appreciable changes. It is, however, the no less true that the oxidability of this metal is extreme.

An old experiment of Jahn's (*Berichte*, 1875) shows that contact with a trace of mercury is sufficient to cause an abundant and magnificent efflorescence, due to the oxidation of the aluminium. Le Bon has examined this reaction in greater detail, and we will return to it later on.

Deville, Dumas, Ditte, Moissan, Riche, Hugouencq, Balland, and numerous other chemists having examined this metal, have observed the ease with which it becomes oxidised in the presence of small quantities of iron and silicon. These are, in fact, the principal impurities of aluminium. Actual nodules of alumina are formed under certain conditions at the places where the metal is no longer homogeneous.

The progress of the industry has enabled me to prepare metals sufficiently pure for the attack caused by water, chlorides, the alkalis, and various foods to be relatively weak.

But if we examine the chemical affinities of the relatively pure metals, from the theoretical point of view, when they are in the form of powder, the refractibility of the aluminium is far from remaining the same.

Aluminium Powder.

Aluminium powder is prepared commercially by submitting the hot pure metal to certain mechanical treatment. Most of these powders contain a variable proportion of fatty matters.

When we treat aluminium powder, freed from fat by means of ether, with hydrochloric acid it is almost completely dissolved. The insoluble residue, according to some authors, consists of carbon, silicon, and traces of aluminium, and does not exceed 0.6 per cent of the total mass.

The estimation of the aluminium in hydrochloric solution, by precipitation with ammonia, does not give more than 94 per cent of aluminium and iron together. The difference, at least to a great extent, is due to oxygen. We have proved this in several different manners.

Methods for the Rapid Estimation of Metallic Aluminium in the Form of Powder.

1. *By the Weight of Hydrogen given off during the Attack by Hydrochloric Acid.*—In a flask of 500 c.c. capacity, fitted with a stopper carrying a funnel with a tap, and communicating on the one hand with an apparatus for making pure carbonic acid gas, and on the other with drying tubes of sulphuric acid in pumice stone, and a tube containing oxide of copper heated to dull red, we place 0.5 to 1.0 grm. of the weighed substance wrapped up in a cigarette paper.

Add a little water, and close the apparatus. After having washed out the air by means of a current of carbonic acid, there only remains to proceed with the attack with hydrochloric acid of one-third strength poured in through the funnel. During the attack, which is made very rapid by heating on the water-bath, the current of carbonic acid is stopped as much as possible; it also serves to wash out the hydrogen at the end of the operation.

The hydrogen reduces the oxide of copper, and the water formed is collected in a tared sulphuric acid and pumice stone tube. Taking the atomic weight of aluminium at 27, we find that 1 grm. of aluminium gives 1 grm. of water. By means of a three-way cock placed in the circuit we can re-oxidise the copper in air, and dry the tube if necessary.

The Tared Tube.—The tube should be tared while full of carbonic acid and weighed with the two ends closed. A second pumice and acid tube should be placed in series to prevent the access of atmospheric moisture to the tared tube. One particular sample gave us in four operations, 91.0, 91.28, 91.3, and 91.67 per cent. When once this apparatus is set up rapid results can be obtained.

2. *Estimation by the Reduction of Ferric Sulphate.*—A. Wahl has described a beautiful and rapid method for the estimation of zinc powder, based on the reduction of ferric sulphate by this powder. We have endeavoured to apply the principle of this method to aluminium. The reaction should be as follows: $3\text{Fe}_2(\text{SO}_4)_3 + 2\text{Al} = \text{Al}_2(\text{SO}_4)_3 + 6\text{FeSO}_4$, from which we find that one part of iron corresponds to 0.1607 of aluminium.

Application.—Into a narrow necked flask we weigh out 5 decigrams of the metallic powder. After the addition of 20 grms., that is to say, a large excess of ferric sulphate without action on permanganate, we add about 50 c.c. of water. The flask is closed by means of a stopper having two tubes suitably arranged for a current of carbonic acid to bubble through the mass during the whole of the operation. As the reduction only takes place when hot, the flask is placed on the water-bath. At the end of an hour, the aluminium powder has disappeared, and the ferric sulphate is completely dissolved. After cooling rapidly in the current of carbonic acid, the solution is completed and made acid by the addition of 20 c.c. of concentrated sulphuric acid. There only remains to dilute to 250 c.c., and to estimate the ferrous salt on a known portion of the liquid by means of a titrated solution of permanganate of potassium.

With a solution of permanganate containing 3.163 grms. per litre, for example, 1 c.c. corresponds to 0.00062968 of aluminium. It is better, however, to work with more concentrated solutions of permanganate. Our experiments have given us a mean of 91.4 per cent of aluminium, a result which concords with the other method. We have already stated that impurities are present in the sample; these are particularly silicon and iron. It is possible to make certain that it is only the iron which is the cause of error. We may, in fact, assume that it exists in the metallic state, and consequently gives rise to a disengagement of hydrogen during the first process of the estimation, and to a reduction of permanganate in the second. It is quite otherwise in so far as the silicon is concerned in aluminium powder. Some observations are here necessary on this subject.

The state in which the Silicon exists in Powdered Aluminium.

Silicon is a body which is capable of existing in three separate states: the amorphous, the crystalline, and the graphitoid. The amorphous form, according to Deville (*Ann. Chim. Phys.*, [3], vol. xlix., p. 68), is oxidisable in warm air, and is only soluble in hydrofluoric acid. The two other very stable forms are equally unattacked by any other acids than the mixture of hydrofluoric and nitric acids (Deville).

In the aluminium powder treated with hot dilute hydrochloric acid we observe a very slight insoluble residue. It is quite possible that this residue may contain graphitoid silicon. We know that by electrolysis the sodico-aluminic chloride Sainte-Claire Deville observed the existence of graphitoid silicon in the metal. This silicon comes from the electrodes of siliceous carbon, which, on contact with the hot aluminium, introduces silicon into the aluminium.

But this small amount of graphitoid silicon insoluble in acids does not represent the whole of the silicon present. In fact, when we evaporate the filtered hydrochloric solution to dryness, and leave the residue for a sufficient time in the oven at about 170° in a platinum crucible, the silica is rendered insoluble. In our experiments this amount was equal to 0.608 of silicon. This is quite sufficient to show that there is silicon in the aluminium powder. We may remark here that Deville states that silicised aluminium

becomes inflamed when heated, and burns with remarkable brilliancy, with the formation of silicon and silicate of alumina. To sum up, the silicon present in aluminium powder is only to a slight extent in the form of insoluble silicon, but principally as silica. These observations should be borne in mind in making the analyses.

Direct Detection of Alumina in Aluminium Powder.

The difference between the percentage of aluminium precipitated and estimated in the form of alumina in a liquid free from silica, and the percentage of the metal obtained by one of the two processes, gives, within the errors due to iron, sodium, &c., the quantity of pure oxidised aluminium which is present in the powder. The following is one of these analyses:—

	Per cent.
Aluminium and iron	91.20
Alumina	5.80
Silica	1.30
Graphitic and insoluble silicon (not estimated) ..	0.40
Carbon	0.23
Moisture and loss (by difference)	1.07
Total	100.00

But we have endeavoured to apply direct methods; in other words, to separate the alumina and the silica from the remainder of the powder, and for this purpose we have undertaken various experiments.

Before dealing with this point let us observe that M. Moissan has described (*Comptes Rendus*, vol. cxxi., p. 794) a method for the estimation of the original alumina. He passed a current of chlorine over the substance placed in a tared boat, and heated to reddish-white heat in a porcelain tube. The metallic aluminium is volatilised in the state of chloride, and the fixed residue when weighed gives the alumina.

We have endeavoured to make the alumina insoluble by submitting the aluminium powder to a prolonged heating above 200°. It appeared to us advisable to first examine methodically the oxidation of this substance at different temperatures.

Wohler observed (*Ann. der Chem. u. Pharm.*, vol. xciii., p. 249) that aluminium heated in oxygen burned vigorously. We have repeated this experiment with our powder, and we found that at a bright red heat it takes fire and burns with brilliancy, giving rise to the formation of a mass of oxide, covering globules of the fused unoxidised metal; the proportion of metal oxidised under these conditions is about 50 per cent. However, the fact is well known, and has been observed on many occasions. The same action does not take place when the metal is in strips. M. Matignon in his work on aluminothermics (*Revue Generale des Sciences*, November 15, 1903) shows that in this case the metal melts under a very thin layer of alumina, which protects it from further oxidation; we have also observed this fact.

Now what happens to aluminium powder heated in air to temperatures below its fusion-point? Is it unchanged to the point generally thought to be the case with aluminium, even in the presence of certain quantities of iron and silicon? This does not appear to be quite the case according to our experiments. The following are a few of the results we obtained:—

Aluminium Powder kept in the Oven at 100° for a Week.—No increase in weight.

Aluminium Powder kept in the Oven at about 175° for a Week.—There were slight but variable increases in weight according to the experiment; in one there was no increase; thus the results are uncertain.

Under these circumstances, as we have been able to prove, it is only possible to insolubilise alumina with great difficulty. We have succeeded partially by leaving a sealed tube containing the metallic powder and another tube with chloride of calcium in the oven for a long time. The process is not practicable, however.

Aluminium Powder heated in the Air to about 400.— Very rapid oxidation. A method for its estimation can be devised from this.

Experiment.—Heat the aluminium powder in an ordinary current of air for twelve hours in a tared boat.

Weight of substance... 0.3217 grm.
Increase due to heating in air... 0.0263 "

If we attribute this increase to oxygen, it represents 0.058 grm. of alumina. If we take up the aluminium powder with hydrochloric acid, after weighing, an abundant residue remains consisting of alumina and insolubilised silica. This residue in this experiment was washed, dried, and weighed; after calcination it gave 0.814 of alumina and silica together.

The difference between the total alumina and the alumina due to oxidation is the original alumina (and silica) in the material. In this case it was 7.7 per cent. So that the analysis of the powder gives:—

Metallic Al and Fe... 91.2
Silica and alumina... 7.7

This insolubilisation of the alumina can also be brought about in hydrogen under certain circumstances. We shall return to this point in another part of our research.

Oxidation of Aluminium Powder in the Cold.—The work done since Wöhler and Deville, establishes the corrosive action of a number of compounds on impure aluminium. We will add a few new observations on this subject.

It is known that when we put aluminium in contact with a solution of chloride of aluminium a sub-chloride is formed. In the same manner Berzelius observed the existence of a subsulphate by putting hydrated alumina and sulphate of alumina together.

We are of the opinion that under certain conditions, such as follows, a sub-oxide of aluminium is formed; aluminium may react directly on hydrated alumina in the following manner:—

1. When, by means of ammoniacal precipitation, we obtain alumina, and when we add powdered aluminium to the liquid thus containing dilute ammonia and ammonia chloride, after a little time we observe that the metal completely disappears in the gelatinous mass. The latter becomes perfectly white. When dried in vacuo after filtration and washing, the powder obtained does not show a single metallic particle when examined under the microscope.

2. Powdered aluminium put in contact with hydrate of alumina, in water, only shows this action to a partial extent after twenty-four hours.

3. Powdered aluminium in contact with alumina in a distinctly ammoniacal solution, but not containing a sensible amount of hydrochlorate of ammonia, produces the same phenomenon as described above in par. 1.

4. Powdered aluminium in the presence of hydrated alumina, in a dilute solution of hydrochlorate of ammonia, without free ammonia, only undergoes partial transformation in the same interval of time.

5. Aluminium powder placed in ammoniacal water, without hydrated alumina, is only slightly attacked.

6. Finally, powdered aluminium placed in a neutral solution of hydrochlorate of ammonia only undergoes slow and partial transformation.

It results from the above observations, that aluminium powder is oxidised on contact with alumina; this oxidation is particularly rapid and is also complete in ammoniacal liquor. We are continuing this research.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 5.

Society of Arts Silver Medal.—The Council of the Society of Arts have awarded Mr. Thomas Tyrer the Society's Silver Medal for his paper on "The Need of Duty-Free Spirit for Industrial Purposes," and the presentation of the Medal will take place at the opening meeting of the Society's session in November next.

THE BECKMANN REARRANGEMENT: TRANSFORMATION OF ACETOPHENOXIME INTO ACETANILIDE AND ITS VELOCITY.*

By Prof. C. A. LOBRY DE BRUYN and C. H. SLUITER.

AMONG the many intramolecular rearrangements known in organic chemistry, the one associated with the name of Beckmann belongs to one of the most important series on account of the extent of its region and its scientific significance. As is well known, it consists in the transformation of the oximes, under the influence of a certain number of reagents, into the isomeric acid amides; for instance, $R_2C=NOH \rightarrow RCONHR$. Its extent is obvious if we remember that all ketones and aldehydes are capable of yielding oximes, and that a large number of these, particularly of the ketoximes, can undergo the re-arrangement. Its scientific importance is chiefly due to the fact that its application to the stereoisomeric ketoximes has been the means of determining the configuration of those stereoisomers, in this manner:—

The rearrangement generally takes place under the influence of different reagents, such as sulphuric acid, hydrochloric acid, phosphorus pentachloride and oxide, acyl chlorides, acetic acid with its anhydride and HCl, zinc chloride, alkalis. As these substances are always applied in relatively large quantities, it is thought most probable that the actual rearrangement nearly always relates to intermediate products, additive compounds or derivatives of the oximes, which occasionally have been separated.† These intermediate products then contain a negative group (or the group OK) attached to the nitrogen which changes place with the C-combined alkyl- or aryl-group. On subsequent treatment with water the amide is generated. We then have—

That hydroxyl itself can assume the function of the group X which changes place with R' is shown by the interesting observations of Werner and Buss (*Ber.*, 1894, xxvii., 2198), Werner and Skiba (*Ber.*, 1899, xxxii., 1654), Posner (*Ber.*, 1897, xxx., 1693), and Auwers and Czerny (*Ber.*, 1898, xxxi., 2692), who have noticed some cases of the Beckmann rearrangement in the absence of any reagent. Dibenz-

hydroxamic acid, $C_6H_5COCOC_6H_5$, obtained from chloro-

benzhydroxamic acid, $C_6H_5C.Cl$, by means of silver

benzoate, melts at 95°; according to Werner and Buss it changes after some days spontaneously into its isomer, $C_6H_5CO.NHOCOC_6H_5$, m. p. 161°; on heating this takes place more rapidly. Posner observed that o-cyanobenzaldoxime changes into its isomer when simply heated above its melting-point; it first melts at 175°, then solidifies, and finally melts again at 203°. Here we consequently have the direct conversion—

Finally, Auwers and Czerny have found that o-oxo-m-methylbenzophenonoxime, $HO.H_3CC_6H_3C-C_6H_5$, partly

* Koninklijke Akademie van Wetenschappen te Amsterdam. Reported in *Proceedings of the Meeting of Saturday, April 23, 1904*.
† Beckmann, for instance (*Ber.*, viii., 988), obtained $C_6H_5COC_6H_5$ from $(C_6H_5)_2C=NOH$ and PCl_5 . It is very probable that $(C_6H_5)_2C=NC$ is formed first as an intermediate product.

undergoes the Beckmann rearrangement when submitted to distillation.

These observations from Werner and his pupils, of Posner, and of Auwers and Czerny are of fundamental importance for the understanding of the mechanism of the Beckmann rearrangement. They prove that this important transformation is most decidedly a real intramolecular rearrangement, which may occur in some cases with the oxime, but in the majority of cases with derivatives in which, instead of the OH-group, another negative group or a halogen has been attached to the nitrogen. In that case the change from II. into III. represents the actual rearrangement.

Auwers and Czerny have already pointed out that the above rearrangement caused by distillation deserves the closest attention. They are of opinion that this observation leads to the view that the Beckmann rearrangement is a catalytic process which is in accord with Beckmann's own ideas. But is it permissible to speak of a catalytic process when the catalyst is wanting? And do not Auwers and Czerny withdraw their own statement when they say that "es sich vielmehr handelt um die directe Ueberführung eines weniger stabilen System in ein stabileres?"

The Beckmann rearrangement has not, up to the present, been subjected to a dynamical investigation. Such a study is not rendered less desirable or less important by the fact that, as a rule, the rearrangement of the intermediate product and not that of the oximes themselves will be investigated.

The oxime which has been studied in the first place is acetophenoneoxime, of which only one form is known, and which quantitatively passes into acetanilide. Its configuration is therefore—

The rearrangement, which Beckmann found to take place under the influence of concentrated sulphuric acid, was studied in the first place. Before starting it was necessary to work out an analytical method allowing the quantitative determination of the resulting anilide in the presence of the unchanged oxime. After several preliminary experiments it was found that the anilide formed on adding water was completely hydrolysed by boiling for a few hours, and that the acetic acid could then be distilled off and titrated; the excess of oxime did not interfere. We have in consequence determined the velocity with which the anilide was formed. In carrying out the experiments 2.5 grms. of the oxime were dissolved in 50 or 100 c.c. of sulphuric acid, previously heated to the temperature at which the experiment was made (65° or 65°), and at definite periods a certain quantity was pipetted off from the bottle (which was placed in a thermostat) and analysed.

The reaction proved to be one of the first order, the velocity constant did not change with the concentration; so it is a monomolecular one. At 65°, for instance, $k = 0.0097$ for a solution of 2.5 grms. of the oxime in 50 as well as in 100 c.c. of 93.6 per cent sulphuric acid (time in minutes; transformation of half of the oxime after one hundred and sixty minutes).

The transformation velocity increases with the concentration of the acid as shown from the following table:—

Temperature 60°.	Velocity-constant.	Time of half transformation.
Concentration H_2SO_4 .		
93.6	0.0011	275 mins.
94.6	0.0013	232 "
97.2	0.0038	75 "
98.7	0.0070	43 "

At 65°, 86.5 per cent sulphuric acid gave a constant of 0.0006 (time of half transformation = 501 minutes). When using 99.2 per cent acid at 60°, practically all the oxime had been converted after fifteen minutes.

The influence of the temperature is apparent from the following figures:—

At 60°, 93.6 per cent H_2SO_4 , $k = 0.0011$; 94.6 per cent H_2SO_4 , $k = 0.0013$.

At 65°, 93.6 per cent H_2SO_4 , $k = 0.0097$; 94.6 per cent H_2SO_4 , $k = 0.0021$.

The temperature coefficient for 10°, is therefore about 3. A solution of SO_2 in chloroform did not appear to cause any transformation of the oxime.

The results of this research therefore confirm the view that in the Beckmann transformation we are dealing with a real intramolecular rearrangement. Even if the application of sulphuric acid should cause the formation of an intermediate compound (which has not yet been positively proved, but which is very probable*) our experiments show that this formation (or the conversion I. into II.) takes place with immeasurably great velocity. The very perceptible development of heat which occurs on mixing the oxime with the concentrated sulphuric acids also points to this fact.

Addendum.—Of late years, Stieglitz and his co-workers (*Am. Chem. Journ.*, 1896-1903) have been engaged in the study of the Beckmann rearrangement. In my opinion Stieglitz's ideas cannot be accepted in their entirety. Recently this chemist has given a summary of his conclusions in a separate article on the "Beckmann Rearrangement" (*Am. Chem. Journ.*, 1903, xxix., 49). He then arrives at the following views:—

The analogy of the Hofmann transformation of the amides into amines with the Beckmann rearrangement—an analogy first pointed out by Hoogewerff and Van Dorp (*Rec.*, vi., 373; viii., 173)—and the fact that the acid azides of Curtius are converted with elimination of nitrogen into the same isocyanates which occur as intermediate products in the Hofmann transformation, induces Stieglitz to attempt to explain these reactions from a same point of view. He believes that in the three above transformations there must be formed intermediate molecule residues containing univalent nitrogen; with the azides, for instance, $\text{CH}_3\text{CO.N.N}_2 \rightarrow \text{CH}_3\text{CO.N} + \text{N}_2$; with the bromamides, for instance, $\text{CH}_3\text{CONHBr} \rightarrow \text{CH}_3\text{CO.N} + \text{HBr}$. These molecule residues are then supposed to be converted straight into the isocyanate, $\text{CH}_3\text{CO.N} \rightarrow \text{CONCH}_3$. In order to arrive, in the transformation of oximes into amides, at such molecules with univalent N atoms, Stieglitz assumes that first of all HCl is attached to the oxime, owing, for instance, to the action of—

this additive compound, under the influence of PCl_5 , then loses one molecule of water, and gives $\text{R}_2\text{CCl}-\text{N}$, which molecule residue is then supposed to be converted into $\text{RCCl}=\text{NR}$, which on treatment with water yields the amide.

Now, first of all it is difficult to see where the HCl, which gets attached to the oxime, is to come from; it is of course known that some oximes yield with PCl_5 compounds such as R_2CClN with formation of HCl, but this is not the formation which Stieglitz had in mind. We also fail to see how sulphuric acid, acting as dehydrating reagent, will, in the rearrangement, cause a molecule of water to be first attached, and then to be again eliminated; neither do we understand how the transformation under the influence of, say, P_2O_5 or ZnCl_2 , can be reconciled with the ideas of Stieglitz. Finally, Stieglitz himself admits of his own theory that "it does not agree so well with the more obscure relations of the theory of stereoisomerism of ketoximes and their influence on the rearrangement of these isomers. It is hoped that future work will remove this difficulty" (*Am. Chem. Journ.*, [7], xxix., 67). The difficulty is this, that Stieglitz's theory utterly ignores a fact of fundamental importance, namely, the formation of two different amides from the stereoisomeric ketoximes; these according to Stieglitz ought to lead to the same intermediate product from which the same amide only could be formed.

* If to an ethereal solution of the oxime is added a solution of sulphuric acid in ether, a precipitate is obtained, the nature of which will be investigated.

And finally the transformations of an oxime into the isomeric amide without any reagent whatever, as observed by Werner and his co-workers, by Posner, and by Auwers and Czerny, are directly opposed to his representations.

In his last theoretical paper, Stieglitz attributes the transformation of some more hydroxylamino derivatives to the intermediary formation of molecule residues with univalent nitrogen; he includes all these under the name of "Beckmann arrangement."

I think I have shown that this classification is not permissible. If it were so the Hofmann transformation might claim priority over the "Beckmann arrangement," which is of more recent date.

In order to avoid confusion I think it absolutely necessary to let each of the said transformations retain its own name and to treat them as separate reactions. In the Curtius transformation, $\text{CH}_3\text{CON}.\text{N}_2 \longrightarrow \text{CONCH}_3 + \text{N}_2$, the assumption of the intermediary occurrence of a molecule residue $\text{CH}_3\text{CO.N}$ is permissible; in the Hofmann reaction, $\text{CH}_3\text{CONHBr} \longrightarrow \text{CONCH}_3 + \text{HBr}$ such is

possible but not necessary; NCH_3 may also have

been formed as an intermediate product (Hantzsch); finally we may admit in the Beckmann rearrangement—

($\text{X} = \text{Cl}, \text{Br}, \text{OH}, \text{or } \text{SO}_3\text{H}$ [respectively H_2SO_4], OCOCH_3), a same mechanism as in the Hofmann transformation, but, according to my opinion, not the presence of a molecule residue with univalent nitrogen.

The physico-chemical investigation of the Beckmann rearrangement is being continued.

NOTICES OF BOOKS

Directions for Laboratory Work in Physiological Chemistry. Second Edition. By HOLMES C. JACKSON, Ph.D. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1903.

The second edition of this manual of practical physiology has been thoroughly revised, and some additions, which experience showed to be desirable, have been made to it. The fact that it is designed mainly for the use of medical students explains, and also justifies, the special emphasis which has been laid on some parts of the subject, which is treated most thoroughly and systematically. The concise and explicit descriptions of the experiments are such as to make the book eminently fitted for being placed in the hands of students, though the practice of constantly introducing hints by means of questions interspersed in the text, which is regarded with such great favour by some teachers, is perhaps rather overdone here. Some account of the detection of the various elements in the compounds most frequently met with in organic nature would have made the book more complete, but on the whole the subject is presented in a thoroughly scientific aspect, and the book is well suited to its purpose.

A Laboratory Manual of Physiological and Pathological Chemistry. By Dr. E. SALKOWSKI. Authorised Translation from the Second German Edition by W. R. ORNDORFF, A.B., Ph.D. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1904.

The original edition of this book was rightly received most favourably in Germany, and a translation of it into English will no doubt be equally welcome in our own land. Though the text might be regarded as open to criticism in some comparatively unimportant details, among which might be

mentioned, for example, the inclusion of pages devoted to the preparation and standardisation of normal solutions, which ought to have been made familiar to the student of physiology by means of a preliminary study of pure chemistry, yet on the whole the book will be found to be unrivalled, especially for guidance in advanced work. For many reasons it is less suited to elementary students, chief among them being a certain want of system displayed in places, and the brevity of some of the directions for the experiments, but in other respects and for other purposes it can hardly be too highly recommended, and will no doubt be regarded as practically indispensable by physiologists and advanced medical students.

Elementare Vorlesungen über Telegraphie und Telephonie. 6. Lieferung. ("Elementary Lectures on Telegraphy and Telephony." Part VI.). By Dr. RICHARD HEILBRUN. Berlin: Georg Siemens. 1903.

THE sixth number of these lectures concludes the description of the Morse system, and deals fully with the Hughes apparatus, which is described as simply and intelligently as possible. It may safely be said that these lectures could not be improved upon, and post office and telegraph officials could not do better than study them with the utmost thoroughness. They will be found to contain all that is necessary for a satisfactory acquaintance both theoretical and practical (as far as it can be acquired from books) with the subject, and the author cannot be too highly congratulated on the interesting manner in which he has treated telegraphy and the eminently readable little book he has produced, which, though it might truly be styled popular in one sense, is thoroughly scientific in all its explanations, and contains no slipshod or only approximately accurate statements, as is so often the case with elementary treatises of this kind.

Die Elektrometallurgie der Alkalimetalle. ("The Electro-metallurgy of the Alkali Metals"). By H. BECKER. Halle-a-S.: Wilhelm Knapp. 1903.

THIS monograph on the preparation of the alkali metals gives for its size a very complete account of the subject. A short introduction describes early attempts at the extraction of the metals potassium and sodium by chemical means, but the greater part of the book is devoted to electro-chemical methods, which are grouped into two divisions—electrolytic and electrothermic. Sodium is naturally treated at the greatest length, and the references to current and patent literature throughout are very complete, useful notes being given on articles of special importance, such as, for instance, the paper by M. Le Blanc and J. Brode on the electrolysis of caustic soda, which appeared some time ago in the *Zeitschrift für Elektrochemie*. Potassium and lithium and electrothermic methods, having regard to their comparative unimportance, receive but little attention, and an appendix contains some hints on the apparatus most conveniently employed in the laboratory for the purpose of preparing the alkali metals.

Quantitative Analysis for Mining Engineers. By EDMUND H. MILLER, Ph.D. New York: D. Van Nostrand Company. 1904. Pp. 137.

The volume before us is one for specialists only, as it deals with quantitative chemical analysis only as applied to a limited section of the Mining Engineer's work. It consists entirely of a series of articles which appeared in the *School of Mines Quarterly*, vol. xxx.

The author explains that no attempt is made to cover the entire field of inorganic analysis, but a few important analyses are given in considerable detail. A little knowledge is a dangerous thing, and a student who had gone even carefully through this book would be in the unfortunate position we have hinted at, and at the same time

might consider himself competent to take up the position of chemist at some mining or metallurgical works.

As a book of reference in particular cases this volume may be useful, though such important subjects as gold and silver assaying are omitted.

There is no index.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 22, May 30, 1904.

Chemical Effects of Light. Action of Hydrochloric Acid on Platinum and Gold.—M. Berthelot.—The author makes a series of experiments on the chemical effect of light, and finds that pure platinum is slowly attacked by fuming hydrochloric acid under its influence. The presence of manganous chloride assists the reaction considerably. In fact, the reaction is double in proportion if the chloride is present. Its presence is, however, not indispensable. Light apparently acts in these cases in the same manner as atmospheric air when the latter is used as an oxidiser for organic compounds. It seems to cause the fixation of free oxygen, which replaces the chlorine of the hydrochloric acid. Viewed in this manner, the action can also be compared to that of electrolytic oxygen.

Solubility of Silicon in Silver. A variety of Crystalline Silicon which is Soluble in Hydrofluoric Acid.—H. Moissan and F. Siemens.—The authors find that silicon is much more soluble in silver than in either lead or zinc. On crystallising out the silicon from its solution in silver the solidified metal is found to contain a certain proportion of an allotropic variety of silicon which is soluble in hydrofluoric acid.

Formation of Vanadium Ores in Nature.—A. Ditte.—Lead vanadate is almost the only vanadium ore found in nature in abundance. This mineral is found either simple or combined, as in lead chlorovanadate. The author accounts for this fact by considering the action of natural waters which circulate both hot and cold, under a more or less pressure, under the earth's crust. The disintegrated rocks, containing considerable quantities of vanadium, cause this water to become charged with vanadic acid and vanadates more or less soluble in water. These vanadium-charged waters come in contact with the principal minerals—galena, anglesite, cerusite, &c.,—which are partially transformed into lead vanadate, in which the vanadium from the different minerals in which the metal was originally distributed amongst the rocks is concentrated.

Synthesis of a Series of Tertiary Alcohols Derived from Cyclohexanol.—Paul Sabatier and Alph. Mailhe.—The authors synthesise the tertiary alcohols derived from cyclohexanol by the action of cyclohexanone on organo-magnesium compounds derived from the reaction of magnesium on fatty or aromatic halogen derivatives. Cyclohexanone reacts briskly, and if the solid crystalline mass obtained is decomposed by iced water the alcohol is prepared, usually with a good yield, $\text{CH}_2<\begin{smallmatrix} \text{CH}_2-\text{CH}_2 \\ \text{CH}_2-\text{CH}_2 \end{smallmatrix}>\text{COH-R}$; R being the aromatic or fatty residue which constituted the organo-magnesium compound.

Acetylenic Aldehydes. New Method of Preparation. Action of Hydroxylamine.—Ch. Moureu and R. Delange.—The authors prepare the acetylenic aldehydes, $\text{R}-\text{C}\equiv\text{C}-\text{CH}(\text{OC}_2\text{H}_5)_2$, by the action of ethylmagnesium bromide or methylmagnesium iodide in etheral solution on an acetylenic hydrocarbon in a reflex condenser. After twenty-four hours of boiling, the gaseous evolution having

completely stopped, a small excess of orthoformic ether is added and the whole again heated for twenty-four hours. Finally, the mixture is cooled with iced water, and the acetal remains in the ether layer and can be extracted by distillation. The yields of the acetals are about 75 per cent.

Bulletin de la Société Chimique de Paris.

Series 3, Vol. xxix., Nos. 20—21.

Chemical Equilibrium between the Ferro- and Ferri-hydrocyanic Acids.—Maurice Prud'homme.—Already inserted in full.

Chemical Equilibrium between the Ferro- and Ferri-cyanides of Potassium in the presence of Alkalis.—Maurice Prud'homme.—Already inserted in full.

The Preparation of Glutaconate of Ethyl.—E. E. Blaise.—The usual method adopted for the preparation of glutaconate of ethyl is the etherification of glutaconic acid obtained according to MM. Conrad and Guthzeit's method. This method, however, is troublesome and expensive, and the author has found, in the dehydration of β -oxyglutarate of ethyl a process which is much more practical and economical; the oxyglutaric acid being prepared by the hydrogenation of acetonedicarbonic acid.

Methylation of Glutaconate of Ethyl.—E. E. Blaise.—Already noticed.

Condensation of Glutaconate of Ethyl.—E. E. Blaise.—Already noticed.

Synthesis of 2-2-dimethylglutaric Acid.—E. E. Blaise.—Already noticed.

Preparation of Adipic Acid.—L. Bouveault.—Finding the older methods inadequate the author has had recourse to the electrolysis of a very concentrated aqueous solution of ethylsuccinate of sodium, and here again he found the results low compared with the energy exerted, owing to the increase of resistance caused by the heating of the solution. Eventually, after making considerable modifications in the apparatus and method employed, he succeeded in getting a better return of adipate of ethyl, though it did not exceed 40 per cent. Finally by the electrolysis of succinic anhydride he succeeded in obtaining a regular return of 70 per cent of pure adipate of methyl. To transform this adipate of methyl into adipic acid it is heated for ten hours in a steel autoclave at 200° with ten times its weight of water. Alkaline saponification must be avoided because of the difficulty of separating the adipic acid from the salts with which it is mixed, which difficulty is caused by its greater solubility in water than in ether or any other solvent not miscible with water.

The Secondary Products of the Electrolytic Preparation of Adipic Acid.—L. Bouveault.—Among the secondary products of this reaction described by the author is β -oxypropionate of ethyl, which is split up into iodide of ethyl and β -iodopropionic acid when treated with gaseous hydroiodic acid. Another body is adipate of ethyl, and another is a tribasic acid with the formula $\text{C}_{15}\text{H}_{26}\text{O}_6$. A further body obtained is an acid succinate of ethyl having the formula $\text{C}_9\text{H}_{16}\text{O}_4$, while an oily liquid, boiling at 194° at 20 m.m., has the formula $\text{C}_{12}\text{H}_{20}\text{O}_6$.

On Rhodinamine.—L. Bouveault.—The author describes the preparation of a new body he calls rhodinamine, which differs from rhodinol only by the changing of the oxyhydrile into an amidogen group. This rhodinamine is capable of combining with one molecule of water under unexpected conditions which were first discovered by accident. The first time it was prepared he was attempting to dry the etheral solution by means of powdered solid potash. The ether, when distilled off, left a slightly viscous liquid which did not contain a drop of rhodinamine, and boiled at 140° at 15 m.m. Analysis showed that the base had combined with 1 molecule of

water, forming a tertiary amine-alcohol of which the constitution is represented by the formula—

Hexahydrobenzoic Aldehyde, Hexahydroacetophenone and the Corresponding Secondary Alcohol.

—L. Bouveault.—The author has recently prepared the hexahydrobenzylic alcohol by treating hexahydrobenzoate of ethyl with sodium and absolute alcohol. He oxidised this alcohol to obtain the corresponding aldehyde, but the return is low, as part of the alcohol is oxidised to the state of hexahydrobenzoic acid, and part to the state of hexahydrobenzoate of hexahydrobenzyl. The hexahydroacetophenone, $\text{C}_6\text{H}_{11}\text{---CO---CH}_3$, is a colourless liquid boiling at 68° under 12 m.m. It has a fresh, agreeable odour, recalling that of the fatty acetones of similar molecular weight. It combines readily with bisulphide of sodium, giving a crystallised compound, decomposed by the alkaline carbonates. It is very difficult to obtain free from water.

Action of Oxygen on the Organo-halogen-magnesian Derivatives.—L. Bouveault.—A molecule of chloride of benzyl, dissolved in ether, was treated with an atom of magnesium in a flask fitted with a bromine tube and a vertical condenser. When the reaction was over the bromine tube was replaced by a tube terminating in a funnel and plunging into the liquid, and perfectly dry pure oxygen was passed through. The oxygen was absorbed integrally with the evolution of sufficient heat to keep the ether boiling for the two hours the reaction lasted. On cooling, the liquid thickened rapidly and became changed into a solid white mass, consisting, no doubt, of the compound $\text{C}_6\text{H}_5\text{---CH}_2\text{---O---Mg---Cl}$. This mass was treated with water, then with dilute sulphuric acid; the ethereal solution which separated out was washed and distilled, and an 80 per cent return of perfectly pure benzylic alcohol was obtained.

Chlorination of *p*-Amido and *p*-Oxy-*o'*-*p'*-dinitrophenylamine by means of Chlorate of Sodium and Hydrochloric Acid.—F. Reverdin and P. Crépieux.—A long paper in which the authors describe their methods, and give analyses of the products obtained.

Purification of Natural Mineral Waters by means of Carbonate of Barium.—G. Arth and P. Ferry.—The authors find that both the lime and magnesia are precipitated by boiling with carbonate of barium, though the magnesia does not disappear to any great extent; for example, with two molecules of the carbonate and seventy-two hours' agitation at the ordinary temperature there was a loss of 50 per cent of magnesia, and after six hours' boiling the loss was only 36·6 per cent.

MISCELLANEOUS.

Examination of Nitrifying Microbes.—E. Boulanger and L. Messol.—The authors have examined the conditions of culture of the nitric and nitrous ferments. The nitrous ferment is killed by heating to 45° for five minutes; the nitric ferment to 55° ; the best temperature for the cultivation of both ferments is 37° . The nitrification is accelerated by cultivating the ferments on coke placed in revolving barrels. The production of nitrite is arrested in liquids containing 30 to 50 grms. per litre of sulphate of ammonia, it is retarded by 8 or 10 grms. of nitrite of magnesia, and stopped by 13 to 15 grms. The nitrates of soda and potash interfere in doses of 1 to 5 grms. per litre. Those of lime and magnesia at 1 per cent at least. The transformation of nitrites into nitrates is made difficult by the concentration of the medium in nitrite or nitrate; it is stopped by a dose of 20 grms. per litre of nitrite or 25 grms. of nitrate. Nitrate of lime retards nitration in a

dose of 12 grms. per litre.—*Ann. de l'Institut Pasteur*, vol. xvii., No. 7, p. 492.

The Maximum Density of Aqueous Solutions of some Organic Bodies.—W. Mueller.—The addition of water to organic bodies of different compositions (phenol, pyrocatechin, resorcin, hydroquinone, pyrogallol, phloroglucin, mannite, glucose, oxalic, succinic, and tartaric acids) gives rise, at the temperature of maximum density, to very different molecular lowerings. As in the mineral bodies already studied from this point of view, the lowering observed is nearly proportional to the concentration of the solution (alcohol is an exception to this law); however, we observe in the case of most of the bodies examined, that the molecular lowering increases a little with the concentration, and this variation is not sufficiently slight to be explained by errors of experiment. It is apparently caused by a partial association of the molecules of the substance dissolved. The variation of the maximum of density does not appear to depend only on the molecular weight of the substance dissolved; its chemical constitution also exercises a considerable influence. This variation increases with the number of hydroxylised groups; it augments (at equimolecular concentrations) in the series, phenols, diphenols, triphenols; also in the series, succinic acid, tartaric acid. The three diphenols give nearly the same value; there is a little greater difference between the two triphenols. Finally, the increase of the molecular lowering with the concentration, very marked in the case of the ortho-phenol, is slight with the meta-, and does not occur at all with the para-phenol. This result is explained by the tendency of pyrocatechin to give double molecules in concentrated solutions, a tendency which is only found in a less degree with resorcin, while it no longer apparently exists in the case of hydroquinone.—*Zeit. Physik. Ch.*, vol. xliii., p. 109.

The State in which some Superoxygenated Acids and their Salts exist in Solution.—L. Pissarjewsky.—The superoxygenated acids obtained by the action of peroxide of hydrogen (pertungstic, permolybdic, peruranic acids) give off peroxide of hydrogen when they are destroyed by an acid. For this reason the author is inclined to look upon them as salts of this peroxide. To justify this hypothesis, he determined the manner in which the salts of these acids are decomposed in aqueous solution, by the method of parting with ether, and by measuring the conductivity. Thus, he found that the peruranate UO_8Na_4 is a salt of the feeble acid $\text{UO}(\text{OH})(\text{O}_2\text{H})_2$; in aqueous solution it is hydrolysed into NaOH and H_2O_2 , and phenomena of equilibrium take place between the undecomposed salt and its products of decomposition. On standing this solution gives a deposit of the acid $\text{UO}(\text{OH})(\text{O}_2\text{H})_2$, which is but slightly soluble. Solutions of pertungstic acid contain the acids $\text{WO}_2(\text{OH})(\text{O}_2\text{H})$, $\text{WO}_2(\text{O}_2\text{H})_2$, and probably also at a low temperature, $\text{WO}(\text{OH})(\text{O}_2\text{H})_3$ and $\text{WO}(\text{O}_2\text{H})_4$. The two first of these acids are hydrolysed in aqueous solution, with the formation of peroxide of hydrogen. As for the pervanadates $\text{V}_5\text{O}_{26}\text{K}_8$, the first is a salt of a monobasic acid, and the second a compound of the salt of pyropervanadic acid, which is quadribasic, and of that of metapervanadic acid, which is monobasic. The aqueous solutions of perborate of sodium at 25° contain BO_2Na , NaOH , Na_2O_2 , BO_3H_3 , H_2O_2 , and traces of BO_3Na . This latter salt forms in quantities which are greater as the temperature is lower; at 0° the solution contains nothing but this salt.—*Zeit. Physik. Ch.*, vol. xliiii., p. 160.

Use of N-rays in Chemistry.—H. Becquerel.—The author finds, as was predicted from an examination of the Blondlot radiations, that there are two orders of chemical phenomena according as, say, alkalis act on metallic sulphates or metallic sulphates act on alkalis, and these two orders of chemical phenomena correspond to the two methods of emission. The experiments were made with baryta in aqueous solution and at ordinary temperatures.—*Comptes Rendus*, cxxxviii., No. 23.

BATTERSEA POLYTECHNIC, S.W.

The Governing Body require the Services of a LABORATORY STEWARD and LECTURE ASSISTANT in the University Department (Day and Evening).—For particulars send stamped addressed envelope at once to the SECRETARY.

UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH.

ASSISTANT LECTURER AND DEMONSTRATOR IN CHEMISTRY.

The Council invite applications for the Post of ASSISTANT LECTURER and SENIOR DEMONSTRATOR in CHEMISTRY.

Applications, together with copies of testimonials, should reach the undersigned, from whom further particulars may be obtained, not later than SATURDAY, JULY 9, 1904.

T. MORTIMER GREEN, Registrar.

June, 1904.

To CHEMISTS (METALLURGICAL & ANALYTICAL).

A well-arranged Suite of Laboratories, with an Office attached, To Let in Victoria Street. The laboratories newly fitted with all the latest improvements and conveniences for Analytical work. Gas and Electric current, and good Water supply. £120.—Apply, Secretary, 34, Victoria Street, London, S.W.

Chemical Works, manufacturing Chemical Manures on a large scale. Recent death of a Director leaves vacancy on Board for a Gentleman having £5000 to £7000 to invest. Security certain.—Write "Chemical," care of Gould's Advertising Agency, 54, New Oxford Street, London.

Wanted in a Chemical Laboratory in London, a Student-Assistant (sixth on staff). Applicants, who should preferably not be more than twenty-one years of age, should have studied at one of the colleges recognised by the Institute of Chemistry, and should have satisfied the requirements of the Institute in regard to preliminary training. The work is of a varied nature, and the selected candidate would obtain a good training in one or two branches of Applied Chemistry, and there would be a prospect of promotion. A small salary would be given to a suitable man.—Address, "Analyst," CHEMICAL NEWS Office, 16, Newcastle Street, Farringdon Street, London, E.C.

To WHOLESALE MANUFACTURING CHEMISTS.

Wanted, complete information as to Camphor Refining. Sodium Hydrate Stick Moulding, or other Chemicals of profitable nature, by firm in N.E. Lancashire.—Address, in confidence, J. J. CHEMICAL NEWS Office, 16, Newcastle Street, Farringdon Street, London, E.C.

ZINC

Suitable for the MARSH-BERZELIUS Test for ARSENIC. As described in the "Report of the Inland Revenue Departmental Committee on Arsenic-Testing."

VOL. XC., No. 2328.

ON FLAME SPECTRA.*

By CHARLES DE WATTEVILLE.

In order to obtain the spectrum of any substance, it has generally been considered sufficient to introduce a small quantity of it into an already formed flame. In the course of a photometrical investigation of flames which had been coloured by injecting the spray from saline solutions into the gas to be burnt, M. Gouy discovered in the spectra of the flames several new lines belonging to the metal contained in the solution (*Annales de Chimie et de Physique*, 1879, 5th Series, vol. xviii.). Instead of appearing throughout the whole flame, as did the previously known lines, these new lines were only emitted in the vicinity of the inner blue cone—the origin of the Swan spectrum. The observations of M. Gouy were limited to the examination of certain lines of the visible portion of the spectrum, and, with the advice of Professor Schuster, and under his direction, I have taken up this study with the object of extending it, by means of photography, to the ultra-violet portion of the flame, and also of detecting lines which are too feeble to be visible to the eye.

The method employed for the production of the flame is, in short, that which has been introduced by M. Gouy and described by him in his memoir, to which reference should be made for a description. The very slight modifications which have been made in the apparatus of this scientist are due to the necessity of having an arrangement which should be as automatic as possible during the eight hours which were often found necessary for the photographic exposures. These modifications, however, have an important bearing upon the success of the experiments.

The spectroscopical apparatus used has been of two kinds—a fine Rowland concave grating of 1-metre radius and prism spectroscopes. The results obtained by means of the grating have been completed, as regards the very weak lines, with the help of the prism spectroscope.

The lines in the spectra obtained under the conditions of my experiments are very much more numerous than is the case when all the portions of the flame do not participate in the production of the phenomena. Not only are all the lines present which were seen by Professor Hartley in the oxy-hydrogen blowpipe flame, but, in addition, there are a large number of other lines which only extend to the height of the blue inner cone. Moreover, the flame spectra extend sufficiently far into the ultra-violet in order to enable the line 2194 of tin to be observed.

If we compare the flame spectra thus produced with those of the arc and the spark it will be noticed that, as a rule, the lines which are found in the flame spectrum are those which are the strongest lines in the arc spectrum. In certain cases some of the more intense arc lines are absent, whereas less intense arc lines are to be found in the flame spectrum. On the other hand, none of the characteristic lines of the spark spectrum are ever seen in the flame spectrum. The resemblance, however, is very marked between the flame spectrum and that of the spark which has been made oscillatory by the introduction of a self-induction into the discharging circuit of a condenser. In the latter case, as is well known from the work of Dr. Hemsalech, the spark spectrum is considerably simplified ("Sur les Spectres d'Étincelles," Paris, Hermann). Moreover, although the flame spectrum will contain only the lines which belong to the spectrum of the oscillatory spark, yet all the lines of the latter will not be found in the flame spectrum, the missing lines being those which are

peculiar to the ordinary spark spectrum, and which only exist in the immediate neighbourhood of the electrodes, becoming shorter and shorter, and finally disappearing as the self-induction is increased.

The preceding paragraph refers to metals other than those belonging to the iron group. On the contrary, there is a most striking similarity between the flame spectra of iron, of nickel, and of cobalt, and the oscillatory spark spectra of the same metals in the region included between about 4300 and 2700 Angstrom units. The similarity of the two spectra is so great that, except for very small differences of intensity, the oscillatory spark spectrum, which is photographed as a comparison spectrum in the centre of the flame spectrum, appears to be a prolongation of the latter. It should be noticed that if in the visible portion of the spectrum certain lines appear to be missing, it is doubtless because the continuous spectrum prevents these feeble lines from being seen. This explains why M. Gouy was not able to observe the nickel lines which are found on the photographs taken with various salts of nickel, viz., the sulphate, chloride, and ammoniacal chloride. In the ultra-violet the spectrum of the flame appears to fade away a little more rapidly than that of the oscillatory spark, but it is probable that this difference would be reduced by prolonging the time of exposure, since it is, of course, the radiations of the shortest wave-length which are most absorbed by different media.

It is very probable that the reason for this similarity between the spectrum of the flame and the spectrum of the oscillatory spark is entirely a question of temperature. On the one hand, the increase in the number of lines of the flame spectrum obtained by the use of the sprayer may be attributed to the fact that the hottest regions of the flame take part in the production of the phenomena, and, on the other hand, the diminution in the number of lines in the spark spectrum when the spark becomes oscillatory is due to a diminution of its temperature.

THE DECOMPOSITION OF AMMONIA BY HEAT.*

By E. P. PERMAN, D.Sc., and G. A. S. ATKINSON, B.Sc.

THIS subject has been already dealt with by Ramsay and Young (*Journ. Chem. Soc.*, 1884, vol. xlv., p. 88) who heated ammonia in glass tubes at various temperatures, and found that decomposition began under the most favourable circumstances at a little below 500°, and that the amount decomposed depends on the extent of the heated surface of the solid with which the ammonia is in contact, on the nature of the surface, and on the time of exposure to heat.

We have thought it desirable to extend our knowledge of the subject still further by investigating the rate of decomposition at various temperatures. The ammonia was contained in porcelain vessels heated in a muffle furnace, and the decomposition was traced by reading the pressure on a mercury manometer, the sum of the volumes of the ammonia, and products of decomposition being kept constant. The difficulty of finding the amount of ammonia in the vessel at the beginning of the decomposition was overcome by heating the ammonia at the end of a series of observations until complete decomposition was caused; the pressure and temperature were then noted, and the original amount of ammonia calculated. We have confirmed the observations of Ramsay and Young that the decomposition is never absolutely complete, but after heating at a temperature of 1100° for a short time the amount of ammonia remaining is so small that it can be neglected for practical purposes.

Apparatus.—The ammonia was heated in a porcelain globe A (Fig. 1) of about 2 litres capacity by means of a muffle furnace, B; the capillary stem of the globe was connected with a capillary glass tube by a copper sleeve and

* Abstract of a Paper read before the Royal Society, June 16, 1904.

* A Paper read before the Royal Society, June 16, 1904.

some fusible alloy. The pressure gauge D stood 2 metres high, and the level of the mercury was regulated by a movable reservoir, F. The pressure was read on a millimetre scale; G is a movable piece of mirror glass of rectangular shape, and with a horizontal line drawn across it; by sliding it along the edge of the millimetre scale and behind the glass tubes of the gauge, the readings were made with great facility.

H is a U-tube with a stopcock at the bottom; its object was to cut off the ammonia from the three-way stopcock K by a column of mercury, and so prevent or indicate leakage. One branch of the stopcock K led to a water-air pump, and the other to a long tube L containing caustic soda, and thence to a cylinder of ammonia with a safety escape M, consisting of a tube dipping into a column of mercury.

was found to be free from carbon dioxide. A quantity of pure hydrochloric acid was neutralised by passing the gas from the cylinder through it, and the solution was then evaporated to dryness. Chlorine was then estimated in the sample by the gravimetric method, and the percentage found was (1) 66.09; (2) 66.12; mean, 66.105; theoretical, 66.23.

Method of Work.—The furnace was heated, and when the temperature was sufficiently constant, the filling process was commenced. The globe was exhausted, and ammonia admitted from the cylinder through the drying tube L; this was repeated from eight to ten times, when the filling was regarded as complete. Readings of pressure were then made at definite time intervals, and the temperature was also carefully noted, as nearly as possible at the same time, by means of the pyrometer. In one or two of the experi-

FIG. 1.

Measurement of Temperature.—Temperature was measured by means of a Callendar-Griffiths pyrometer. The disturbing effect of the current of hot air passing over the projecting head of the thermometer was avoided by surrounding the head with several turns of tinned iron. The temperatures were read to 0.1° C. The thermometer was carefully standardised with melting ice, boiling water, and boiling sulphur, and we do not think that the temperature error can in any case exceed 0.5° C.

Thermostat.—To maintain the temperature constant an Ostwald pattern regulator was used, the vessel being of porcelain, and containing air. In addition to this a Fletcher gas regulator was fixed on the main supply. Any variation of temperature caused by alteration of the barometric pressure was corrected by means of a screw at the bottom of the U-tube containing the mercury. It was found convenient to adjust the gas supply to give the required temperature by loading the valve of the Fletcher regulator.

Material.—The cylinder of ammonia was obtained from the Standard Anhydrous Ammonia Company, and was found to contain but very little impurity. In one experiment about 20 litres of ammonia were passed slowly through a long worm surrounded by ice and hydrochloric acid, but nothing appreciable was condensed. The gas

remains the temperature was sufficiently high to decompose the ammonia completely in a short time, but in most of them, when a sufficient number of readings had been made, the temperature was raised until (practically) complete decomposition ensued in a few minutes. The volume of the ammonia and decomposition products was kept constant by raising the mercury reservoir F so as to keep the mercury at about the same level in the upper part of the short limb of the pressure gauge. As each time interval was called, the level of the mercury in D was read, and that in the open limb as soon as possible afterwards; it did not change quickly in the latter, owing to the width of the reservoir.

Some observations were also made on the effect produced by sudden change of pressure on the rate of decomposition.

Method of Calculation.—The ultimate decomposition of ammonia is customarily represented by the equation $2\text{NH}_3 = \text{N}_2 + 3\text{H}_2$. Let p_1 be the pressure of the ammonia in the globe at any instant during the decomposition; p_1' , that of the nitrogen; p_2' , that of the hydrogen; P , the total pressure at the same instant; p_0 , the initial pressure of the ammonia at the beginning of the experiment.

Then—
$$p_1 + p_1' + p_2' = P \quad \dots \dots (1),$$

also—
$$p_2' = 3p_1' \quad \dots \dots (2),$$

and—
$$p_1' + p_2' = 2(p_0 - p_1) \quad \dots \dots (3),$$

FIG. 2.

FIG. 3.

expressing that (1) the sum of the partial pressures is equal to the total pressure; (2) the pressure of the hydrogen produced is three times that of the nitrogen; (3) the sum of the pressures of the nitrogen and hydrogen is double the pressure of the ammonia decomposed.

From this it follows by substitution that $p_1 = 2p_0 - P$, i.e., the pressure of the ammonia at any instant is double the initial pressure minus the total pressure at the instant of observation. The experimental data furnish values of P and $2p_0$, and $2p_0 - P$ has been tabulated giving the pressure of ammonia at the time of observation. From these numbers corresponding values of $\Delta P/\Delta t$ have been calculated by taking the mean of the two consecutive differences and dividing by the time interval; but $P/\Delta t = dP/dt$ approximately within the limits of experi-

mental error, and $dP/dt = dp_1/dt$, and therefore we have the rate of change of the pressure of the ammonia at definite pressures, they have been plotted in two series of curves.

Results.—The rate of decomposition was found to be much influenced by the state of the globe; it invariably increased after the globe had been used once or twice, owing probably to the action of ammonia or hydrogen upon the porcelain; consequently we were not able to trace the effect of temperature on the rate of decomposition. In the first experiments the projecting stem of the globe was allowed to become too hot, with the result that a trace of the alloy at the joint c found its way into the globe, and by its catalytic action increased enormously the rate of decomposition of the ammonia. The alloy contained a small

proportion of mercury, and a film of this metal was found on the interior of the globe when it accidentally broke. In the later experiments great precautions were taken to maintain the stem of the globe at a low temperature. The experiments are here tabulated to serve as a key to the curves.

Mean temperature.	Greatest variation of temperature.	Remarks.
791°	$\pm 0.2^\circ$	Traces of mercury present.
750	0.6	
841	0.2	New "clean globe," pressure fell only 20 m.m. in 2 hours.

26	1358.9	9.6	1.9
28	1362.5	6.0	—

$2p_0$ is taken as 1368.5, which was obtained by extrapolation of the time-pressure curve.

These results are best understood from the curves shown in Fig. 2 and Fig. 3, having values of dp_1/dt as ordinates and of p as abscissae.

Fig. 2 shows the lower and Fig. 3 the higher ratio of decomposition. The curves, as a rule, do not depart much from straight lines, and at the highest temperatures, 1061° and 1111°, become straight lines, or very nearly so. These results indicate that at the highest temperatures the decomposition is of the first order, i.e., it is monomolecular, pro-

ceeding according to the equation $\text{NH}_3 = \text{N} + 3\text{H}$; the union of the atoms to form molecules is probably so quick that it can be neglected when compared with the rate of decomposition of the ammonia molecule. The departure from this mode of decomposition at lower temperatures is possibly caused by the volume and mutual attraction of the molecules. No formula has yet been devised to express the results satisfactorily.

In the presence of substances having a catalytic action, the resulting curve is altered in character, the curvature being greater at the higher pressures. This is well shown in the curves at 750° and 791° (Fig. 2), mercury vapour being present, and in those at 797° and 1025° (Fig. 3), when iron wire and platinum black respectively were present. In these two latter experiments it will be noticed that the rates of decomposition reached and passed those without catalyser for about 100° higher.

Effect of Sudden Change of Pressure on the Rate of Decomposition.

As a final experiment the effect of a sudden change of pressure was tried, the globe containing both iron wire and finely divided platinum. The change of pressure was brought about by allowing the gases in the globe to blow off into the air for a few seconds, and a reading of the pressure gauge was made as soon as possible afterwards.

Time.	Pressure-gauge.	Bar.	Total pressure.	ΔP .
7.4	335.2	760.8	1096.0	20.8
9	356.0	"	1116.8	19.6
14	375.6	"	1136.4	
7.16	58.2	760.9	819.1	15.2
21	73.4	"	834.3	14.7
26	88.0	761.0	849.0	

The ratio of the pressures before and after the change is $1136.4/819.1 = 1.39$, and that of the ratio of decomposition (taken approximately from the values of ΔP) is $19.6/15.2 = 1.29$.

The agreement is sufficiently close to show that the reaction is essentially of the first order, or monomolecular, apart from the little understood disturbing influences (see van't Hoff's "Vorlesungen," 2nd edition, p. 234).

Summary and Conclusion.

The rate of decomposition of ammonia has been investigated under various conditions; the containing vessel was of porcelain. The temperatures varied from 677° to 1111°. It was found that the reaction is essentially monomolecular, being similar to that for arseniuretted hydrogen, as found by van't Hoff. The rate of decomposition is much quickened by the presence of traces of some of the metals, those tried being, mercury, iron, and platinum.

We are indebted to the Government Grant Fund of the Royal Society for the cost of most of the apparatus employed, and wish to express our great obligations to Principal Griffiths for the loan of some of his apparatus for platinum thermometry, and for his kind guidance in its use.

Supplementary Note, May 27, 1904.—We have assumed that the decomposition of ammonia is an irreversible reaction, i.e., $k = 0$ in the general formula $dx/dt = k(a-x)(b-x)$ $-k'(a'+x)(b'+x)$ for Ramsay and Young showed (*loc. cit.*) that on passing a mixture of dry nitrogen and hydrogen through a heated glass tube containing iron filings, or through a red-hot iron tube, no appreciable quantity of ammonia was formed, a result which we confirmed by experiments of our own some years back, obtaining the same result also with a glass tube containing porcelain. We find, however, that this view of the matter is not generally accepted; Ostwald, for instance, in his "Grundlinien der Anorganischen Chemie" (1900, p. 345) states that, on heating ammonia, equilibrium ensues when 98 per cent of the ammonia is decomposed. We should like to point out that the results of our experi-

ments, now described, show no indication whatever of any such equilibrium, for the curves all run towards the origin within the limits of experimental error, whereas, if there were any equilibrium before the ammonia was all decomposed, they would cut the horizontal axis to the left of the origin, and, moreover, the equilibrium would change with the temperature.

We have mentioned that a trace of ammonia was always found in the globe at the end of an experiment, but this probably came from the cold stem; and, moreover, since the rate of decomposition may be taken as proportional to the amount of ammonia present, that amount can, strictly speaking, never quite reach the zero point.

Whether a minute quantity of ammonia remains finally undecomposed would not be indicated by these results, and we intend to approach the subject from another direction, and to examine generally the conditions under which nitrogen and hydrogen combine to form ammonia.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Ordinary Meeting, Wednesday, June 15th, 1904.

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

MESSRS. G. Dean, C. D. McCourt, J. C. Smith, R. de J. Fleming-Struthers, and C. H. Thompson were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. William H. R. Allen, care of Straits Trading Co., Butterworth, Penang, S.S.; Jabez Horace Cooper, 13, Victoria Terrace, Exeter; George Frederick Phillips, B.Sc., Colworth Road, Leytonstone; Edwin Roy Watson, B.A., B.Sc., 1, Fair Street, Cambridge.

A ballot for the election of Fellows was held, and the following were subsequently declared duly elected:—Albert Ernest Bellars, B.A.; Herbert Frank Brand, M.A.; W. Edgington Field; Thomas Alfred Gerard; James Gray Gilchrist, M.A.; John Hulme; Herbert Jenkins; John Haslam Johnson, M.Sc.; Rudolf Lessing, Ph.D.; Frank Harold Lowe, B.Sc.; William Edward Oakden; Alfred Pell; David John Pinkerton; Robert Rodger; Percy Richard Sanders; Charles John Sawyer; Henry Stanley Shelton; John Weinberg; James Alfred Wilkinson, M.A.

The President stated that six of the seven Past Presidents to whom the Society desired to do special honour at the Banquet held in 1898 having passed away, the Council felt that there should be no further delay in the publication of a memorial notice of the life and work of each. Arrangements had accordingly been made for the preparation of such notices, which, it was hoped, would be incorporated in the volume of *Transactions* for the present year. The list includes the name of Frankland, concerning whom a Memorial Lecture had been delivered by Professor Armstrong at a special meeting of the Society in October, 1901. Repeated application for the manuscript having been unsuccessful, and nearly five years having elapsed since the death of Sir Edward Frankland, the Council were arranging for the preparation of an independent obituary notice.

The President further stated, for the information of the Society, that arrangements had been completed for the publication annually of Reports on the Progress of Chemistry under the several heads employed in the *Journal* for the classification of the Abstracts, with addition of a new section on "Radio-activity." It was expected that these reports, collected into an extra number of the *Journal*, would be ready for issue to the Fellows early in the spring of each year.

The attention of the Fellows was also requested to the notice inside the cover of the *Journal* relating to the Inter-

national Tables of Atomic Weights, which are now printed on cards to be obtained from the Society's Agents, Messrs. Gurney and Jackson.

Of the following papers, those marked * were read:—

*III. "The Mechanical Analysis of Soils and the Composition of the Fractions resulting therefrom." By ALFRED DANIEL HALL.

The object of the investigation was to ascertain the effect of introducing into the mechanical analysis of soils a preliminary treatment of the soil in dilute acid followed by ammonia as first suggested by Schlesinger. For the separation into fractions, the beaker method of sedimentation as worked out by Osborne was adopted, the soil being divided into two fractions by sieves and five by sedimentation from water. Eighteen soils of known history were selected from the Rothamsted experimental plots, to give comparisons of the same soil in an unmanured condition and when rich in humus through the accumulation of organic matter.

The proportions in which the groups of particles of given sizes occur in a soil are presumably constant for the particular type of soil; the actual state of aggregation of the particles at any given time or place determines what may be termed the texture of the soil and depends on a number of temporary factors, such as the cultivation to which the soil has been subjected, the amount of humus present, the use of lime or of saline manures, &c. It is held that no method of mechanical analysis can measure the existing texture of the soil, although that texture does ultimately depend on the size of the particles composing the soil. If, however, the method of mechanical analysis can be made to show the ultimate physical constitution of the soil, a measure is obtained of the capacity of the soil to acquire a known texture under given methods of cultivation.

On comparing the results obtained by sedimenting the Rothamsted soils with and without the preliminary treatment in dilute acid, it is found that the raw soil rarely yielded as much of the finest or "klay" fraction as did the same soil after washing with acid, and that the difference was greatest when pastures and other soils rich in humus were examined, but practically disappeared with soils which had been deprived of their humus and deflocculated by long treatment with saline manures. As no valid reasons exist for supposing that the acid treatment can break down large particles into smaller ones, it is concluded that in carrying out a mechanical analysis on the raw soil mang aggregates of the finest particles are left unresolved, but fall apart when the humates, which act as a weak binding material, are removed by the treatment with dilute acid followed by ammonia. A further action of the acid treatment is to remove all traces of soluble salts, which would otherwise cause flocculation and interfere with the sedimentation. It is only when dealing with soils containing a fair amount of humus that there will be much difference between the results obtained by the two methods, but, inasmuch as only the acid treatment yields an exact sorting out of the ultimate inorganic particles of the soil, whereas working on the raw soil leaves some of the finest particles still unseparated, the general conclusion is reached that the acid treatment should be adopted in all cases.

With the Rothamsted soils, the method involving a preliminary treatment with acid shows the essential identity of soils from the same experimental field whatever the manuring has been, whereas the analyses made on the raw soil give very different results, depending on the treatment the various plots have received.

Determinations made of the alumina, silica, and ferric oxide in the various fractions separated by mechanical analysis show that although the proportion of alumina increases as the particles composing the fraction become smaller, these fractions do not possess any chemical individuality, but are determined by the size and not by the chemical composition of the particles.

*112. "The Effect of the Long-continued Use of Sodium Nitrate on the Constitution of the Soil." By ALFRED DANIEL HALL.

On reviewing the results of the mechanical analysis of Rothamsted soils, it was observed that those which had been manured with sodium nitrate every year gave abnormal results; a further series of fifteen soils was examined drawn from each of the Rothamsted fields where plots with and without sodium nitrate occurred. In general, the use of sodium nitrate has resulted in a lower proportion of "clay" being left in the surface soil. This result was most manifest in the mangel field, where cultivation is frequent, and was not apparent at all in the grass field, where the turf protects the soil from the washing action of the rain.

The removal of the finest particles from the surface soil is attributed to deflocculation induced by the use of sodium nitrate and followed by the washing of the finest particles into the subsoil. This hypothesis is confirmed by chemical analysis of the "klays" separated in the mechanical analysis, by mechanical analysis of some of the subsoils, which were found to be richer in fine particles beneath the soils receiving nitrate, and by the condition of the same soils in the field, which showed every evidence of deflocculation.

DISCUSSION.

Dr. VOELCKER said that although he could not go so far as Mr. Hall in his estimation of the value of mechanical as against chemical analysis of soil, he nevertheless recognised the importance of the former and the advance which had been made with regard to it. It seemed, however, remarkable in the first paper that such similarity of composition was shown in the different separations formed by washing the soils.

In regard to the second paper, he could, from his own experiments on the Woburn soil—a light sandy one and very different to that at Rothamsted—quite bear out what had been noticed with respect to the action of sodium nitrate. On washing the former soil continuously with solutions of this salt, the finer portions of soil were carried down and the subsoil after a time became quite different in texture, forming a consolidated mass through which the water would not percolate. This was due, no doubt, as the author had indicated, to the carrying down of the finer particles. In this respect great differences were noted between the action of sodium nitrate and that of the sulphate and other salts of ammonium.

Dr. E. J. RUSSELL pointed out that what was really wanted was a knowledge of the total surface of the soil particles to a depth of say six inches; mechanical analysis gave very useful results but was not entirely satisfactory. There are some fundamental objections to the method; small particles from near the bottom of the column of liquid are deposited along with the larger particles which take the same time to travel from the top, and the deposit is therefore a mixture. Moreover, a disc-shaped particle will tend to place itself broadside on and be deposited simultaneously with a spherical particle of about the same sectional area. Consequently, it cannot be assumed that the particles have even approximately the same surface, although under the microscope the sediment may appear to be fairly homogeneous.

Mr. F. J. LLOYD said that the study of the physical nature of the soil had been neglected in England, whereas the remarkable researches of Whitney in America had shown that valuable information could be derived from this investigation. He regretted that the author had stated that the physical study yielded more important results than the chemical examination, because in his opinion the nature of the soil could only be discovered by the investigation of both its physical and chemical properties.

Mr. T. S. DYMOND pointed out that the method employed by the author involved the complete disintegration of the soil aggregates produced by years of cultivation. What information of value bearing on the proper treatment of

cultivated land could be obtained if the previous history of the soil were obliterated previous to analysis? More practical knowledge could be gained by the rough examination of the soil of a field with a spade than by the old methods of mechanical analysis. Would not this be still more true of the method now proposed?

Dr. LUXMORE said that as the aim of mechanical analysis was to determine the structure of the soil it was needful in the first place to know the total quantity of the finest materials, which sometimes formed a layer over the coarser particles. If in addition to this a method could be derived by which the state of tilth could also be determined this would be a further advantage. One great benefit of the preliminary treatment with acid lay in the saving of time which it involved in a long and tedious process. From his own observations on the soils of Dorset he knew that the dissolved material other than calcium carbonate was very small in amount.

Mr. HALL, in reply, said that he would not attempt to consider the question raised by Dr. Voelcker and Mr. Lloyd as to the value of the mechanical analysis of a soil; the method, however, aimed at gauging the behaviour of a soil towards water, and the size of crops even in this humid climate was determined more by the amount of water available than by the soil constituents usually regarded as plant food. He agreed with Dr. Russell that the working surface of the soil particles was probably the factor of most importance, and one which could only be imperfectly deduced from the mechanical analysis. He did not, however, anticipate that it would be possible to estimate directly the behaviour of a soil in the field from any of the measurements they could obtain; the function of the mechanical analysis was rather to enable one to relegate a given soil to one or other of certain known types, the working qualities of which had been already ascertained by experience. This meant, then, the accumulation of the necessary data for a number of soils, and the first essential was to obtain a method which was so far accurate that it represented the permanent and not the accidental or temporary features of the soil.

*113. "The Decomposition of Oxalates by Heat." By ALEXANDER SCOTT.

In spite of the simple formulæ given to the oxalates, their decomposition by heat is by no means as simple as usually stated. Ordinary precipitated calcium oxalate turns grey on ignition, and this change, which is due to the separation of small quantities of carbon, occurs even with the purest calcium oxalate. This salt gives very little carbon dioxide and carbon, but always a little of each, decomposing practically in accordance with the equation usually given, $\text{CaC}_2\text{O}_4 = \text{CaCO}_3 + \text{CO}$.

Sodium and barium oxalates decompose in accordance with the following equations—

Magnesium oxalate gives exactly equal volumes of carbon dioxide and monoxide and no carbon, $\text{MgC}_2\text{O}_4 = \text{MgO} + \text{CO} + \text{CO}_2$, but almost all the other oxalates tested gave notable quantities of carbon dioxide and carbon.

*114. "Some Alkyl Derivatives of Sulphur, Selenium, and Tellurium." By ALEXANDER SCOTT.

When sulphur is heated at 180° with methyl iodide, 1 atom unites directly with 3 molecules of the iodide, forming the di-iodide of trimethyl-sulphine iodide, which is obtained as an almost black oil, but after this has been freed from excess of methyl iodide the solid, $\text{S}(\text{CH}_3)_2\text{I}_2$, may be obtained by dissolving the oil in ethyl acetate and precipitating by means of ether, when it separates in dark purple scales melting at 38° . Selenium behaves in an exactly similar way, the $\text{Se}(\text{CH}_3)_2\text{I}_2$ melting at 39° . To reduce these to trimethyl-sulphine and -selenetine iodides, water is added to their solutions in ethyl acetate and hydrogen sulphide is passed in until the liquid is colourless.

As Demarcay has shown, the action of methyl iodide on tellurium at 80° gives rise to tellurium dimethyl di-iodide, $\text{Te}(\text{CH}_3)_2\text{I}_2$, but this is not decomposed by heating to 180°, nor does it give a compound corresponding with those obtained from sulphur and selenium. To obtain tellurium trimethyl iodide, the di-iodide is dissolved in methyl iodide and equivalent quantities of sodium sulphite and sodium carbonate are added. The reaction takes place thus:—

the hydrogen iodide being then neutralised by the sodium carbonate. The tellurium trimethyl iodide is readily separated from the sodium salts by crystallisation.

The di-iodide of tellurium trimethyl iodide, produced by adding iodine to the iodide, is readily obtained in fine purple scales (m. p. 76·5°) by precipitation of its solution in ethyl acetate by means of ether.

Allyl iodide readily dissolves tellurium in the cold, giving an orange-coloured oil, from which the element is very readily obtained again. Ethyl iodide reacts in the same way as methyl iodide.

The author showed several reactions of tellurium dimethyl di-iodide and its derivatives.

*115. "The Ultra-violet Absorption Spectra of certain Enol-ketotautomers. Part I. Acetylacetone and Ethyl Acetoacetate." By EDWARD CHARLES CYRIL BALY and CECIL HENRY DESCH.

An attempt was made to determine the constitution of the metallic derivatives of acetylacetone and ethyl acetoacetate by means of their ultraviolet absorption spectra. The absorption spectra of alcoholic solutions of the aluminium, beryllium, and thorium derivatives of acetylacetone and the aluminium compound of ethyl acetoacetate were photographed, as well as those of the parent substances. Hartley and Huntingdon's method of experiment was adopted, but a different method of drawing the curves of absorption was employed. From a consideration of the absorption curves of acetylacetone and its metallic derivatives, it is evident that the constitution of these substances is very similar, as they all show a strong absorption band, the limits of which are very much the same in every case.

Ethyl acetoacetate, on the other hand, shows no absorption band, whilst its aluminium derivative shows a strong band almost identical with those of the acetylacetone group.

These results appeared at first to indicate that acetylacetone and its derivatives and the aluminium compound of ethyl acetoacetate had the enolic formula, and suggested the keto-formula for ethyl acetoacetate itself. This view was not upheld by the study of the spectra of ethyl ethyl-acetoacetate, and its isomeride, ethyl β -ethoxycrotonate; in both cases, only continuous absorption was obtained without any band at all. The band therefore cannot be characteristic of either the enolic or the keto-modification, but appears to be due entirely to the dynamic isomerism between the two forms. Experiments were made to test this by observing the action of sodium hydroxide or hydrochloric acid, which should materially alter either the size or the persistence of the absorption band; the former reagent should increase it, and the latter decrease it owing to their accelerating and retarding influence respectively on the dynamic isomerism. It was found that a very small amount (1 equivalent) of sodium hydroxide produced a band in the absorption spectrum of ethyl acetoacetate, this band being increased by the addition of more alkali until with excess it was larger and more persistent than that given by the aluminium derivative. Hydrochloric acid was found to have a marked action in decreasing the absorption of ethyl acetoacetate; its action was better observed in the case of ethyl β -aminocrotonate, when it was found that the absorption band was decreased more and more by repeated addition of small quantities of the acid.

The conclusion is therefore drawn that with acetylacetone, ethyl acetoacetate, and their metallic derivatives, a

state of dynamic isomerism exists in the solution; that the presence of the band in their absorption spectra is due to this isomerism, and that its persistence is a measure of the number of molecules in the state of vibration. It would thus appear that the absorption band is a method of measuring the amount of reaction taking place between two isomeric substances which are in equilibrium.

*116. "The Action of Acetyl Chloride on the Sodium Salt of Diacetylacetone and the Constitution of Pyrone Compounds." By JOHN NORMAN COLLIE.

The action of acetyl chloride on the sodium salt of diacetylacetone was investigated with the object of determining whether the introduction of two acetyl groups into dimethylpyrone would destroy its property of forming salts with acids.

As a result of the action of acetyl chloride dissolved in chloroform on the sodium salt, a compound melting at 124° was obtained, which was undoubtedly diacetyldimethylpyrone (compare Thomas and Lefevre, *Bull. Soc. Chim.*, 1888, 1, 103—194). On repeating this operation, the chief substance produced melted at 95·4°, whilst in another experiment, in which the substances were allowed to react at the temperature of a freezing mixture, a compound melting at 75° was obtained.

These three substances were isomeric, having the formula $\text{C}_{11}\text{H}_{12}\text{O}_4$, and were produced according to the equations:—

(1) Diacetyldimethylpyrone gave no coloration with ferric chloride, and could be sublimed; when boiled with barium hydroxide solution, a yellow barium salt was produced, which dissolved in dilute hydrochloric acid and gave a deep red coloration with ferric salts. Bromine was not decolorised by it. The original substance was totally devoid of any basic properties, and gave neither a hydrochloride nor a platinumchloride.

(2) The compound melting at 95° gave a purple coloration with ferric chloride solution, and the orcinol reaction with chloroform and caustic soda. When heated with 80 per cent sulphuric acid, acetic acid and orcinol were obtained; it gave, with bromine, a monobromo-derivative, $(\text{C}_{11}\text{H}_{11}\text{O}_4\text{Br})$ (m. p. 79°), and, with acetic anhydride, a monoacetyl derivative, $\text{C}_{11}\text{H}_{11}(\text{C}_2\text{H}_3\text{O})\text{O}_4$ (m. p. 75°). It dissolves in aqueous soda with a yellow colour, and, after boiling, can be re-precipitated unchanged on the addition of an acid; it is, therefore, diacetylorsinol.

(3) The third substance (m. p. 75°) also gave a purple-red coloration with ferric chloride; it decolorised a solution of bromine in the cold, and, after heating for some time, gave the orcinol reaction with caustic soda and chloroform, but, on warming with this alkali, it also was transformed into the compound melting at 94°, whilst with hydrochloric acid it changed into diacetyldimethylpyrone (m. p. 124°). These curious transformations received scanty explanation from the accepted molecular constitution of dimethylpyrone, and formulae for pyrone and its derivatives were brought forward with the view of explaining the foregoing transformation.

*117. "Our Present Knowledge of the Chemistry of Indigo." By WILLIAM POPPLEWELL BLOMAM.

As the determination of the maximum amount of indigo obtainable at each successive stage of its preparation ("mahai") and of the quantity present in the leaf of the green plant depends on the purity of the indigotin employed as a standard, the author has estimated the percentage of nitrogen in the best specimens procurable, and has thus found that they contain only about 90 per cent of indigotin.

Since the pure substances could not be prepared by the action of solvents on cake indigo or the synthetical product, the crude indigo was sublimed under diminished pressure, and in this way a well crystallised product was

readily obtained which gave the percentage of nitrogen required for indigotin.

This pure material when sulphonated and subjected to analysis by the permanganate method was found to give values ranging up to 300 per cent of the weight of substance taken. As this method is used in ordinary technical analyses of indigo, this result explained the extraordinary variations observed in the published values given for cake indigo and the products obtained during the successive stages of the manufacture ("mahai").

It has also been found that the red substance occurring in the cake obtained from plant-indigo and known as "indirubin" or indigo-red, is not, as stated, a derivative of indigo, as it contains no nitrogen. This material, which may consist of a mixture of compounds, will be further investigated.

118. $\Delta^1:3:4$ "Dihydrobenzene." By ARTHUR WILLIAM CROSSLEY.

Dibromotetrahydrobenzene, prepared by Bayer's method (*Annalen*, 1894, cclxxviii., 88), is a colourless, highly refractive liquid, boiling at $116-117^\circ/29$ m.m. When treated with concentrated alcoholic potassium hydroxide, it yields a small quantity of $\Delta^1:3$ -dihydrobenzene, but principally the ethyl ether, $C_6H_5 \cdot O \cdot C_2H_5$, of hydroxytetrahydrobenzene as a colourless liquid boiling at 155° , and possessing a pungent odour of peppermint.

Quinoline removes two molecules of hydrogen bromide from dibromotetrahydrobenzene, giving $\Delta^1:3$ -dihydrobenzene, which boils at $81.5-82^\circ/767$ m.m., and, like the dihydrobenzene obtained from dihydroresorcin (Crossley and Haas, *Trans.*, 1903, lxxxiii., 494), is characterised by only adding on two atoms of bromine to form 1:4-dibromo- Δ^1 -tetrahydrobenzene melting at 104.5° , and decomposing with evolution of hydrogen bromide at 170° . That this substance is in reality a dibromotetrahydrobenzene is proved by the fact that on treatment with quinoline it loses two molecules of hydrogen bromide with formation of benzene.

119. "The Absorption Spectrum of *p*-Nitrosodimethylaniline." By WALTER NOEL HARTLEY.

It was pointed out that the usual formula assigned to benzoquinone is less consistent with its chemical properties as an oxidiser than the peroxide formula, and that an un-reduced benzene ring is in accord with the optical properties of the substance, since its spectrum exhibits powerful absorption bands. The usual formula, on the other hand, contains the partially reduced carbon ring present in hydro-aromatic substances, and the spectra of these are characterised by an absence of absorption bands. The absorption bands in the ultra-violet are always associated with the production of colours, even when the substance examined shows no visible colour, and such substances are in reality chromogens (*Trans.*, 1887, li., 154-202). Nitroso-compounds of the aromatic series have a powerful and extensive selective absorption in the ultra-violet, and it was thought possible to draw a distinction between these and the closely related oximes.

The following conclusions were deduced:—1. The absorption caused by *p*-nitrosodimethylaniline at the less refrangible end extends into the infra-red, and at the more refrangible far into the ultra-violet. The transmitted rays are thus restricted to a band of yellow and green light bordered on either side by a band of intense absorption.

2. There appears to be a decided difference in constitution as judged by their spectra between *p*-nitrosophenol or quinoneoxime and *p*-nitrosodimethylaniline which cannot be accounted for by a substitution of hydroxyl for the group $N(CH_3)_2$.

3. The alkyl substituted phenols and anilines absorb varying quantities of the ultra-violet, the absorption not extending into the visible spectrum, but the introduction of the NO , as distinguished from the NOH group, extends the absorption far into the coloured rays. This appears to be a characteristic effect of the nitrosyl group in conjunction with the benzene ring.

4. Although the absorption of rays in the blue and violet by *p*-nitrosodimethylaniline is strong, there is at a certain dilution a transmission of the greater part of the ultra-violet.

This explains the action of Wood's screen, which cuts off the visible rays while it transmits some of the ultra-violet. On testing the solutions of *p*-nitrosodimethylaniline, it was found that some red rays were still transmitted, but it is quite possible to adjust the thickness of the solutions so that with a quartz lens and electric light what appears to be perfect darkness causes the fluorescence of uranium nitrate and barium platinocyanide. The appearance of the crystals was brightest when some obscure or feeble blue rays were transmitted.

From a consideration of the facts referred to in connection with conclusion 3, and the previous observations on benzoquinone and its oxime, dioxide, chloroimide, and dichloroimide, it appears to be not improbable that a solution of *p*-nitrosophenol is a mixture of two tautomeric forms, the one a phenol and the other an oxime.

120. "The Influence of Solvents on the Rotation of Optically Active Compounds. Part VI. The Relationship between Solution-volume and Rotation of the Dialkyl and Potassium Alkyl Tartrates in Aqueous Solution." By THOMAS STEWART PATTERSON.

Values for the molecular solution-volumes of dimethyl-, diethyl-, di-*n*-propyl, potassium methyl-, potassium ethyl-, and potassium *n*-propyltartrates are given, and the changes of volume due to solution in water compared with the corresponding changes in rotation. It is shown that in both series a contraction of 1 c.c. per gram-molecule produces the greatest change of rotation in the methyl and the least change of rotation in the *n*-propyl ester, and that the perplexing rotation changes of these compounds, due to solution in water, can at least be brought into harmony when a casual connection between solution-volume and rotation is assumed.

121. "The Constitution of Hydrastinine." By JAMES JOHNSTON DOBBIE AND CHARLES KENNETH TINKLER.

The study of the absorption spectra of hydrastinine, $C_{17}H_{15}O_2N$, has yielded results precisely similar to those obtained with cotarnine (*Trans.*, 1903, lxxxiii., 598).

Solutions of hydrastinine in ether or chloroform, as like the solid substance, colourless, and their absorption spectra are practically identical with the spectra of hydrohydrastinine, a compound which is generally considered to have the constitution represented by formula I. From this it is argued that the carbinol formula II, which represents hydrastinine as differing from hydrohydrastinine only in the replacement of an atom of hydrogen by a hydroxyl group, should be preferred to the open-chain or aldehydic formula of Roser, which would leave the agreement between the absorption spectra of the two substances entirely unexplained.

On the other hand, the aqueous or alcoholic solutions of hydrastinine, which are yellow and fluorescent, give spectra which agree with those of the hydrastinine salts. It would therefore appear that, under the influence of these solvents, hydrastinine changes from the carbinol to the ammonium base, the hydroxyl group shifting from the carbon atom to the nitrogen and forming the complex $>N(CH_3) \cdot OH$.

The spectra of the colourless solutions agree closely with those of the corresponding solutions of cotarnine. The spectra of the coloured solutions possess three absorption bands corresponding in position with two bands in the cotarnine spectra.

All the hydrastinine derivatives examined give spectra

which are identical or nearly so with those of hydrohydrastinine or of the hydrastinine salts.

Alcohol imparts a yellow colour to an ethereal solution of hydrastinine, the depth of colour increasing as the proportion of alcohol to ether is increased. An examination of the spectra of such solutions shows that as alcohol is gradually added the carbinol form changes into the ammonium base form. The opposite change is brought about by the addition of alkalis to the yellow solution of hydrastinine compounds, the disappearance of the fluorescence marking the complete conversion of the ammonium base form into the carbinol form.

122. "The Influence of Moist Alcohol and Ethyl Chloride on the Boiling Point of Chloroform." By JOHN WADE and HORACE FINNEMORE.

Chloroform, when made from alcohol, contains a small quantity of ethyl chloride, the absence of which from chloroform made from acetone detracts from its efficiency as an anæsthetic. The ethyl chloride depresses the boiling point of the chloroform; it was partially isolated by fractionation through a Young's evaporator column, and was identified by conversion into silver propionate.

Incidentally, the authors have isolated binary mixtures of chloroform and alcohol, chloroform and water, and a ternary mixture of chloroform, alcohol, and water, all of minimum boiling point. The first binary mixture boils at 59.4°/760 m.m., has a sp. gr. 1.4125 at 15°/15°, and contains 7 per cent of alcohol. The second binary mixture boils at 56.1°/760 m.m., and contains about 1 per cent of water. The ternary mixture boils at 55.5°/760 m.m., and contains 4 per cent of alcohol and about 3.5 per cent of water. The water in both these mixtures separates at once from the distillate.

123. "Limonene Nitrosocyanides." By WILLIAM AUGUSTUS TILDEN and FREDERICK PEACOCK LEACH.

The nitrosocyanide referred to (*Proc.*, 1902, xviii., 163) by Tilden and Burrows as a liquid is found to be a crystalline, optically active solid, m. p. 90—91°, and $[\alpha]_D + 165^\circ$; it yields a benzoyl derivative, which crystallises in shining plates melting at 107°. The nitrosocyanide has a monomolecular structure, $C_{10}H_{16}NO \cdot CN$, and the formula for limonene having been recently established by Perkin, the nitrosocyanide must be represented as follows:—

This compound is obtained by digesting limonene β -nitrosocyanide with potassium cyanide. It is also the chief product of the same treatment of the mixed α - and β -nitrosocyanides. It has not yet been obtained from pure α -nitrosocyanide, which yields a viscid product, but from the latter a benzoyl compound is obtained, which is identical with the benzoyl derivative of the β -nitrosocyanide. The investigation will be continued.

124. "Photochemically Active Chlorine." II. (A Preliminary Notice). By CHARLES HUTCHINS BURGESS and DAVID LEONARD CHAPMAN.

A considerable number of experiments have now been performed with the purpose of discovering the conditions under which the activity of chlorine gas or its solution is induced and destroyed (*Proc.*, vol. xx., p. 52), the following being a brief summary of some of the results obtained:—

(1) Active chlorine is formed by the action of light or heat on inactive chlorine. (2) Moist chlorine, when heated to the boiling point of water and then cooled to the ordinary temperature, is rendered almost as active as by the action of light. (3) By the passage of the electric discharge through inactive chlorine (compare J. W. Mellor, *Proc.*, vol. xx., p. 140).

It has also been shown that freshly prepared electrolytic gas and chlorine are almost at their maximum activity, and in measuring the activity of either of these gases it is very necessary to make sure that the chlorine contained in the control actinometer is inactive.

It has now been observed that aqueous solutions of certain acids and salts are more effective in removing the activity than pure water.

An active solution of chlorine in water can be prepared either by leaving the liquid in contact with active chlorine or by heating aqueous solutions of chlorine.

Only a very small fraction of the activity is removed by pumping the chlorine out of an active solution under diminished pressure, and when an active solution is distilled in a vacuum both the distillate and the residual liquid are active. Aqueous solutions of chlorides through which ozone has been passed are more active than solutions of the same strength which have not been thus treated.

The residual liquid remaining after removing the chlorine under diminished pressure, when treated successively with potassium iodide and N to thiosulphate, still retains a large proportion of its activity.

The condition of the moist chlorine having been found to be the cause of the induction period, experiments were made for the purpose of deciding whether this phenomenon is due to the formation of a compound of the type $Cl_2 \cdot H_2O$, which is subsequently destroyed by hydrogen with the formation of hydrochloric acid. Comparative measurements of the induction period and of the rate of formation of hydrochloric acid after the induction period were made, and on applying the law of mass action to the results it was seen that if the foregoing assumption is correct, then at least one-half of the chlorine in the actinometer must have been converted into the compound $Cl_2 \cdot H_2O$ before hydrochloric acid began to be formed in appreciable quantity, a result which is obviously absurd.

The conditions of formation of active chlorine precisely correspond with those which are known to be necessary for the substitution of hydrogen in the side chain of a benzene compound.

125. "Additive Compounds of Anhydrous Magnesium Bromide with Organic Oxygen and Nitrogen Compounds." By JOHN JOSEPH SUDBROUGH, HAROLD HIBBERT, and STANLEY H. BEARD.

by the action of a dry ethereal solution of ethylene dibromide on ethyl succinate in the presence of dry magnesium, an additive compound of magnesium bromide and ethyl succinate was obtained. This is an extremely hygroscopic, crystalline solid, which may readily be prepared by the direct union of its components; it has the composition $(CH_2 \cdot CO_2Et)_2 \cdot MgBr_2$.

Additive products of other organic oxygen compounds, such as ether, amyl ether, benzaldehyde, cinnamaldehyde, benzophenone, pyruvic acid, and ethyl benzoate, have been obtained. Amines and nitrites appear to be capable of forming similar additive compounds, whereas hydrocarbons are not.

The compounds are all extremely hygroscopic and difficult to obtain quite pure.

(To be continued).

PHYSICAL SOCIETY.

Ordinary Meeting, June 24th, 1904.

Dr. R. T. GLAZEBROOK, F.R.S., President, in the Chair.

A PAPER on "Chemical Dissociation and Electrical Conductivity," by A. E. GARRETT and Dr. R. S. WILLOWS, was read by Dr. WILLOWS.

It has been shown by Beattie (*Phil. Mag.*, 1899) that a mixture of salt and iodine, when placed on a zinc plate and heated, gives rise to electrical conductivity, although separately no such effect is produced. This is shown to be due to the formation of zinc iodide. Following on this the

electrical conductivity produced by heating various salts is investigated under different conditions of temperature and electric field. A large excess of positive electricity is found in nearly every case.

Mr. SKINNER expressed his interest in the paper, and pointed out that the chief leak did not begin until the iodine was completely vaporised. He asked if the ions were produced in the mixture or in the gas. Had the authors tried the effect of screening the mixture from the electroscope?

Dr. C. CHREE remarked on the fact that the authors employed formulæ of the type $I = at^n$, t representing absolute temperature, under circumstances in which n was a large positive number, in one case as big as 100. To fit such a formula I must be practically either infinitely small or infinitely large, except over a very limited range of temperature. He should like some further details as to the method of arriving at formulæ of a type so remarkable physically, and as to the range of temperature wherein they were supposed to hold.

Dr. WILLOWS, replying to Mr. Skinner, said that the effect was still produced when the mixture was covered with a metal plate, but they had not tried screening with mica. In reply to Dr. Chree, he said that their formula held over a range of 100° C., and that Dr. H. A. Wilson had arrived at a similar formula which applied over a range from 200° C. to 1000° C.

A paper on "The Magnetisation of Iron in Bulk" was read by Dr. W. M. THORNTON.

The paper is in three sections. The first describes a method of measuring large quantities of magnetism by the use of an exploring coil placed around the core and an exciting coil in series with a recording milli-voltmeter. This was applied to determine the complete loops of magnetisation for two rings of cast steel and cast iron weighing respectively 3 and 6 cwt. The results were checked by a quantometer. The second section deals with the curves of rise of magnetising currents, when the core is solid and when laminated, as affected by the reaction of the core-currents, and also by the change of permeability during magnetisation. A second simple method is given of measuring large quantities of magnetism in circuits having a large time constant, suitable for testing dynamo-electric machines. From two curves of rise, with the current in one reversed, expressions are given for finding the total induction in the core and its ratio to the residual magnetism. In the last section an example is given of the sudden dip in the curve of rise observed only with large cores. The growth of current in a coil surrounding a solid circular core is calculated by Heaviside's formula, assuming constant permeability. No dip is found in the calculated curve, and it is therefore caused by a brief magnetic impulse which corresponds to the slip of the molecules at saturation seen in Ewing's model of the magnetisation of iron. Photographs are given showing the direction of flow of eddy currents in cores of rectangular section of proportions 1:1, 1:5:1, and 2:1.

Prof. S. F. THOMPSON expressed his interest in the paper, and referring to the curves showing the rise of the magnetising current, said he thought the explanation given by the author was not the only possible one. He was not inclined to think that the effect was due to internal eddy currents in the core. The fact that the growth of the magnetisation current was irregular was well exhibited in separately excited dynamos with large field magnets, where the effect could be easily seen in the movements of the amperemeter needle. In the author's curves showing the rise of the quantity of magnetism in a circuit with the current, first with the current direct and then with it reversed, he pointed out that a difference would be expected because the core would not be in the same magnetic condition at the beginning of the two experiments.

Mr. W. H. PRETTY said that the question of magnetisation tests of iron and steel in bulk was a very important one. The curves shown by the author suggest the possibility of detecting cavities in steel castings, as such castings

would doubtless give curves differing from those representing a truly solid block of the same material cast at the same time and subjected to the same after-treatment. It would be interesting to have a series of tests on the same block of steel, say, in which each process in the manufacture is represented, i.e., as cast after annealing, and after the surface-scale or skin has been removed to various depths; also after the block has been cut up into slabs or laminæ and put together again. Referring to the dip in the curves of rise of magnetisation observed with large cores, Mr. Pretty said it was not unlikely due to internal mechanical stress and the accompanying strain, and that as it became possible to obtain steel more and more homogeneous such internal molecular changes would become more apparent.

Dr. THORNTON, in reply to Mr. Pretty, said that he was now experimenting upon the effect of cutting up a large core into laminæ and then building up the core again.

NOTICES OF BOOKS

Chemical Novelties for 1904. ("Les Nouveautés Chimiques pour 1904"). By C. POULENC. With 185 illustrations in the Text. J. B. Baillière et fils. 1904. Pp. 352.

THE author has kept to the same plan as in former years. The first chapter deals with chemico-physical apparatus, such as those for the determination of densities, of high temperatures, &c., and a sub-division has been introduced in this chapter for apparatus for the liquefaction of gases by M. Olszewski's methods, by which means these operations have been made more and more practicable, and the returns considerably increased.

In the second chapter we find apparatus for chemical manipulation proper, by which long and difficult operations are much simplified. Among the apparatus for the preparation and purification of gases, we may call special attention to the new one devised by M. Moissan, in which he makes use of the low temperatures given by liquid air, carbonic acid, or oxygen, &c.

Chapter III. deals with electrical apparatus in general, and Chapter IV. with that specially used in analysis.

F. Jean has devised a new and practicable piece of apparatus for the determination of the carbonic oxide and carbonic acid in inhabited places; while among those instruments used for the detection and estimation of arsenic we may call attention to that brought out by E. Bonjean for the detection of this metalloid in pharmaceutical products, and that of G. Bertrand for effecting the same object in animal tissues.

In the fifth and last chapter we find some of the latest apparatus used in the study of bacteriology.

Twenty-eighth Annual Report of His Majesty's Inspectors of Explosives; being their Annual Report for the Year 1903. London: Darling and Sons, Limited. 1904. Pp. 236.

It is satisfactory to read that the inspectors have found no reason to complain of any falling off in the general condition of factories and magazines, and in one instance only have they had occasion to institute legal proceedings for any irregularity, while the occupiers of factories and magazines have invariably shown perfect readiness to remedy such defects as have been pointed out.

The number of deaths from accidents by fire or explosion in the manufacture of explosives is 5, and is below the average for the decade, viz., 6.4. This death-rate cannot be called excessive, and will compare favourably with the death-rate in other dangerous trades.

The total number of factories under continuing certificate or license is 147, being a reduction of 3 during the year.

Four factories have become extinct during the year, and one new one has been confirmed, while there are seven

applications outstanding. Several cases of illegal manufacture of blasting cartridges by miners in their houses were brought to light by accidents during the year. It is to be regretted that, notwithstanding the vigilance of the police, this practice still prevails in certain districts.

In consequence of the accident which occurred at Waltham Abbey in December, 1902, the inspectors considered it advisable to impose further restrictions on the manufacture of cordite M.D. After full discussion with representatives of all the manufacturing firms interested, and of the War Department and War Office Explosives Committee, the character of the restrictions was settled, and these have been embodied now in the licenses of the factories concerned.

During the year, 244 visits have been made to factories, which now number 147, all having been visited at least once, while 476 visits have been made to magazines; in very few instances have serious defects or irregularities been found.

No proceedings for illegal storage have been instituted during the year.

The amount of foreign blasting explosives containing nitroglycerin imported during 1903 was 2,330,582 lbs. against 1,830,277 lbs. in 1902. The corresponding figures for blasting explosives not containing nitroglycerin are 168 lbs. and 2 cases for 1903, against 12,000 lbs. in 1902.

CORRESPONDENCE.

WILLIAMSON'S THEORY OF ETHERIFICATION.

To the Editor of the Chemical News.

SIR,—In the interest of accuracy it seems proper, now that Prof. Williamson is no longer living, to call attention to an error which appears in the latest edition of such a widely used text-book as Richter's "Organic Chemistry," both in the original German and in the American translation (vol. i., p. 134). There it states that Chancel preceded Williamson in publication. The facts are quite otherwise, for Chancel writes most explicitly (*Comptes Rendus*, 1850, xxxi., 521) that he was prompted to immediate publication by the appearance of Williamson's paper, "sans vouloir en aucune façon, faire une réclamation de priorité."

The mistake has doubtless arisen from the fact that although Williamson read his paper before the British Association on August 3, 1850, it was not really published in this country until the November following (*Phil. Mag.*, 1850, [3], 37, 350), whereas Chancel's paper appeared in October. The "British Association Report" (Edinburgh Meeting, 1850, p. 65) contains an abstract, but was not issued until 1851, and the oft-quoted reprint in the *Quarterly Journal of the Chemical Society* did not appear until 1852. On the continent, however, he fared better, the full paper being included in the September number of the *Comptes Rendus des Travaux de Chimie* of MM. Laurent and Gerhardt, to which Chancel refers, two months before its publication in England!—I am, &c.,

F. SOUTHERDEN.

Technical College, Finsbury, E.C.,
July 1, 1904.

PTOMAIN POISONING.

To the Editor of the Chemical News.

SIR,—Having regard to the frequency of cases of ptomaine poisoning through eating canned goods, perhaps you will be able to find room in your paper for one possible explanation of such cases.

A very large proportion of the tinman's solder used nowadays contains 2 or 3 per cent of antimony as an impurity, and it seems possible that the presence of this metal as an impurity may cause electrochemical changes to be set up in the meat or fruit juices, resulting in corrosion of the

solder and consequent production of a line of more or less porous solder, allowing of the infiltration of air laden with micro-organisms capable of establishing a toxic metabolism. I am, &c.,

SIGMA.

MAGNESIA CUPELS.

To the Editor of the Chemical News.

SIR,—Your readers may perhaps like to hear the opinion of an assayer of fifty-five years' experience with regard to magnesia cupels.

I have made numerous experiments with all the known makes, including those supplied by my own firm, and while I am ready to admit that for assays which yield only a minute bead of metal, they are as good as bone-ash (not better), they are unsuitable for those yielding large metallic beads, such as bullion assays; the reason being that the said assays are made uncertain by the large (but variable) quantity of magnesia adhering to the base of the beads so persistently that it cannot be completely cleaned off; this does not, however, occur with well-made bone-ash cupels.

The consumption of bone-ash cupels in my laboratory is over 100,000 a year, so I can speak with some confidence in the matter.—I am, &c.,

A CONSTANT READER.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 23, June 6, 1904.

Method of continuous Recording of the Ionisation of Gases. The Ionograph.—Ch. Nordmann.—The author describes a method by which automatic measurements of ionisation of gases may be taken. The apparatus employed causes a photographic record to be given, by which immediate readings can be taken at any moment without the intervention of further operations when once the apparatus has been started and regulated. The apparatus can be employed for various researches on ionisation and radio-activity.

Influence of Frequency on Electrolysis by means of Alternating Currents.—André Brochet and Joseph Petit.—Up to the present time it has always been admitted that during electrolysis by means of an alternating current frequency has a considerable action on the reactions brought into play, and that the quantity of the products deposited at the electrodes decreases rapidly proportionately as this frequency rises. During the present series of researches the authors prove that this fact is not general, and that frequency has only a very slight action in the case of the particular reactions due to the alternating current, such as the solution of iron and platinum in potassium cyanide or that of lead in sulphuric acid. In the case of nickel and cobalt, frequency acts in a very peculiar manner, quite contrary to that already admitted. As a final result of their investigations the authors state that alternating currents appear to possess electrolytic qualities quite different from those of continuous currents.

Use of N-rose in Chemistry.—H. Becquerel.—Already inserted.

Reduction of o-Nitrobenzylic Alcohol. General remarks on the Formation of Indazylic derivatives.—P. Freundler.—The anomalies which are noticed during the alkaline reduction of the ortho-substituted nitrated derivatives are apparent in a well-defined way in the case of o-nitrobenzylic alcohol. The author shows that this

atter substance does not give the azoic compound when subjected to the action of powdered zinc in presence of alcoholic soda. An investigation on the subject of azoic compounds with ortho-substituted alcohol function leads to a very simple explanation of this fact.

New Method of Preparation of Anilides.—F. Bodroux.—The primary amines react on organo-magnesium compounds in the following manner:— $R-NH_2 + R'-Mg-I = R'H + R-NH-Mg-I$. M. Jot-sitch synthesised acetylenic alcohols and acids from the magnesium compounds of acetylenic carbides which are formed by an analogous mechanism. The author utilises these products of substitution of the amines to introduce the group $R-NH$ into the organic molecule. Carbonic anhydride is apparently without action on these compounds, $R-NH-Mg-I$, but the same is not the case with the ether salts of the monobasic acids. The reaction which the author studies is that of the primary aromatic amines, causing the formation of the corresponding anilides only. It is expressed by the equation:—

MISCELLANEOUS.

Corbin and Stewart's Handbook of Physics and Chemistry.—Messrs. J. and A. Churchill have the pleasure to announce that a section on Light has now been added to the second edition of this work. This subject was originally omitted because, when the new edition was put in hand, it was not included in the curriculum. The new section contains twenty-five illustrations. The book is still published at 6s. 6d.

Kelly's Directory of Chemists and Druggists, 1904.—The tenth edition of this useful Directory has just been published. It includes manufacturing chemists, wholesale druggists, dysalsters, and all other trades connected therewith in England, Scotland, and Wales, and the principal towns in Ireland, the Channel Islands, and the Isle of Man. In the pages of this book will be found the names of over 56,000 persons, being an increase of about 4000 over the last edition. Besides the trade headings, this Directory also includes the more scientific branches, such as analytical and metallurgical chemists, members of the Pharmaceutical Society, and others whose scientific researches are constantly developing important results.

Livingstone College Year-book.—This Year-book contains hints to travellers in matters of health, outfit, and travel, and is published by the Travellers' Health Bureau, Livingstone College, Leyton, E. A special feature of the Year-book on this occasion is a short statement of the risks to health in a tropical climate and the best means of meeting them. This is the first time that such hints have been issued from Livingstone College in a concise form, and it is hoped that later on they will be amplified and form a short guide to health in the tropics. During the past year excellent work has been done in the department of research in tropical medicine, and one by one the great disease scourges of the tropics are being traced to their cause, and are found to be preventable; such work as this deserves every encouragement, and we feel confident that Livingstone College will justify its foundation.

RADIUM

ON SALE AND LET ON HIRE.—Write for terms.

The following can be had by return of post.

Pitchblende, direct from Joachimsthal, very radio-active, from 1/- to 30/- per piece.
Itacolomite, or flexible sandstone, 10/- to 25/- per piece (very rare).
Kunzite, 1/- per gramme. Selected, clear, 2/-
Spartite (see NATURE, 31/3/04, fol. 523), 2/- and upwards.
Chlorophane, 2/- and upwards. Barium Platino Cyanide in large Crystals in course of manufacture. (ORDERS BOOKED).
Zinc Sulphide. Phosphorescing a beautiful Green, 2/6 per tube.
" " " " Yellow, 2/6
Calcium Sulphide " " Violet, 1/-
Radio-active Residue from which Radium is made; very scarce, 2/- tube.
Polonium Sulphide, in tubes of one gramme, 21/-
" on Bismuth Rod or Disc, ... 25/-
" on Copper " ... 25/-
Radio-active Screens (Willemite), 6d. per sq. inch. Plat. Bar. Cyan. Screen, 9d. sq. inch.
" " (Zinc Sulph.), 10 x 10 cm. 7/6.

Professional Men, Universities, Schools, &c., allowed special terms

Our newly invented Thorium Inhalers may be had on hire.

ARMBRECHT, NELSON & CO.,
71 & 73 DUKE ST., GROSVENOR SQ., LONDON, W.

Telephone: GERRARD 4942.

N.B.—We have to-day received a consignment of the New Zealand Vegetable Caterpillar: it is from 2 to 3 inches long, with a stem showing fructification growing out of its head. Scientific name of the insect is *Hepialus virescens*; the name of the fungus is *Sphaeria Robertiana*. Specimens may be had from 10/6 to 21/-, according to quality and size. TERMS CASH WITH ORDER.

Goods may be returned if not approved of, when money will be refunded.

Perfect Order amongst your
Scientific Papers,
Research Records, &c.,

IS SECURED BY THE

"STOLZENBERG"
SYSTEM OF FILING.

The "Unit" of the System is a simple flat File, made in six distinct colours, for classifying under Subjects, &c.

Used by SIR WILLIAM CROOKES, LORD KELVIN, Royal Commission on Tuberculosis, Baden Aniline Works (50,000), and by thousands of private persons as well as Business Concerns.

Satisfaction guaranteed; otherwise goods taken back and money returned.

Sample Set, consisting of 12 best Files, 4to and fcap., with strong nickel-plated Perforator, and Patent Lifter, packed in leather-board box, 10/6 post free.

THE CHEMICAL NEWS.

VOL. XC., No. 2329.

THE RETARDATION OF COMBUSTION BY OXYGEN.*

By HENRY E. ARMSTRONG, Ph.D., F.R.S.

IN the course of his researches on gaseous explosions, H. B. Dixon has laid stress on the fact that carbon monoxide, rather than the dioxide, is the initial product of the combustion of carbon and of its gaseous compounds; moreover, he has shown that water plays a peculiar and all-important part in the combustion of the monoxide; and he has proved, in a number of cases, that oxygen is by far the most effective diluent in retarding combustion. These, in some respects, paradoxical conclusions have not yet been sufficiently explained. Recent researches† emanating from the Manchester school have brought new facts to light, however, which have an important bearing on the interpretation of explosive changes—so much so, indeed, that it is no longer difficult to paint a consistent and fairly complete picture of the mechanism of combustion. (Compare H. E. Armstrong, "The Mechanism of Combustion," *Trans. Chem. Soc.*, 1903, vol. lxxxiii., p. 1088).

1. It would seem that, in the case of hydrocarbons, there is no preferential combustion either of hydrogen or of carbon: initially, the hydrocarbon merely undergoes hydroxylation. As hydroxylation proceeds more readily when it has once taken place—owing to the attraction of oxygen for oxygen—the first product may easily escape observation; thus, Bone and Wheeler were unable to detect the formation of hydroxymethane (methyl alcohol) from methane; Bone and Stockings, however, succeeded in obtaining ethyl alcohol, C_2H_5OH , from ethane, C_2H_6 .

2. A stage in the hydroxylation is soon reached when the thermochisms begin to take place. Thus, dihydroxymethane breaks up as soon as it is formed into water and formaldehyde, which is in turn easily resolved into hydrogen and carbon monoxide:—

Dihydroxyethane, in like manner, gives rise to acetaldehyde, which, under some conditions, breaks up into methane and carbon monoxide:—

3. It is to be supposed that the more complex hydrocarbons are, to a large extent, resolved into simpler thermochisms prior to oxidation, e.g.,—

The change may extend even to the formation of carbon, when a relatively small proportion of oxygen is present. In high temperature changes (explosions), such thermochisms probably play an all-important part.

4. The precise manner in which oxygen is introduced into the hydrocarbon molecule is a matter of some interest. If oxygen molecules were directly active as wholes and the actual, immediate and sole cause of the oxidation, there would seem to be no reason why the dihydroxy-derivative should not be directly produced rather than the monohydroxy; the observation made by Bone and Stockings, that ethyl alcohol is producible from ethane, therefore, is of crucial importance. But on general grounds, regarding the change as electrolytic in character, it is probable that the electrolyte, i.e., conducting water, is the immediate

source of the oxygen; and that the oxygen molecule* plays the part of depolariser. From the same point of view, it appears probable that the water molecules contribute hydroxyl rather than oxygen. The process may be formulated as involving the conjugation of hydrocarbon (probably through its carbon) with water (acting primarily as the catalyst or associating agent) and oxygen, thus:—

5. According to the view here advocated, carbon dioxide is necessarily a later product of change than the monoxide—in fact, the final product. It is to be supposed that, in its formation from the monoxide, the latter is first converted into formic acid. On this assumption, it is easy to understand that the presence of so large a proportion of water is required in order that the explosive wave may attain to its greatest velocity, as the affinity of water for carbon monoxide is relatively slight, and the reversible change one which takes place mainly in the direction:—

The figures given by Dixon are as follows (*Phil. Trans.*, A, 1893, vol. clxxxix., p. 97):—

Condition of mixture.	Per cent of steam present.	Mean rate in metres per second.
Well dried	—	1264
Dried	—	1305
Saturated at 10° C.	1.2	1676
" 20	2.3	1703
" 28	3.7	1713
" 35	5.6	1738
" 45	9.5	1693
" 55	15.6	1666
" 65	24.9	1526
" 75	38.4	1266

The gradual retardation observed when the proportion of steam is increased beyond 5.6 per cent may be due to a variety of causes; to the steam acting as a diluent; to an increase in the extent to which water is unburnt by the carbon monoxide; and, perhaps, in no slight measure, also to the tendency of the steam to hold back the oxygen.

6. It is to this last circumstance that the marked influence of oxygen in retarding combustion is probably attributable. This influence is especially noteworthy in the case of electrolytic gas, inasmuch as excess of hydrogen has precisely the opposite effect, and nitrogen regards the explosion less than does an excess of oxygen. According to Dixon, the rates in metres per second, at which various mixtures of hydrogen and oxygen and of electrolytic gas and nitrogen explode, are as follows:—

4H ₂ : 4O ₂	3532		
3H ₂ : 4O ₂	3527		
2H ₂ : 4O ₂	3268		
H ₂ : 4O ₂	2821		
H ₂ : O ₂	2328	H ₂ : 1O ₂ + 1N ₂	2426
H ₂ : 2O ₂	1927	H ₂ : 1O ₂ + 1½N ₂	2055
H ₂ : 3O ₂	1707	H ₂ : 1O ₂ + 2½N ₂	1822
H ₂ : 4O ₂	1281		

In seeking for an explanation of this remarkable, if not paradoxical, behaviour of hydrogen, it is necessary to remember that, whereas both oxygen and water molecules diminish in stability as the temperature rises, the stability of hydrogen peroxide must be at a maximum at a high temperature—since its formation from oxygen and water is an endothermic process. In fact, it is to be supposed that water is readily oxidised at temperatures such as

* The need of distinctive names for oxygen-stuff or atomic oxygen, and of the molecular oxygen we handle, is very obvious in discussing such a point.

† *Nernst, Zeit. Physik. Chem.*, 1903, vol. xlvii., p. 720, has endeavoured to deduce numerical estimates of the stability of hydrogen peroxide at high temperatures; the results arrived at, however, are not satisfactory owing to the paucity of data.

* A Paper Read before the Royal Society, June 16, 1904.

† W. A. Bone and R. V. Wheeler, "The Slow Oxidation of Methane at Low Temperatures," *Trans. Chem. Soc.*, 1902, vol. lxxxi., p. 536; 1903, vol. lxxxiii., p. 1074. W. A. Bone and W. E. Stockings, "The Slow Combustion of Ethane," *Ibid.*, 1904, vol. lxxxv., p. 693.

prevail in combustions. If, however, the formation of water be regarded as involving the changes—

it follows that water and oxygen will mutually hold each other in check; so that when electrolytic gas is exploded there will be a deficiency of oxygen, as it were, owing to its conversion into hydrogen peroxide, which may be regarded as relatively, if not entirely, inoperative as an oxidising agent at high temperatures in presence of oxygen. On the other hand, when excess of oxygen is present, the water—which is the effective catalyst—will be more or less held back, also in consequence of its oxidation to hydrogen peroxide. The marked influence of hydrogen in promoting the combustion of electrolytic gas is in full harmony with this conclusion; indeed, it is difficult to explain it in any other way than by supposing that, when present in excess, the hydrogen serves to promote the dissociation of the peroxide by diminishing the proportion of active oxygen present; in other words, according as hydrogen or oxygen is in excess, equilibrium is disturbed in one direction or the other. The interaction of hydrogen and oxygen may, perhaps, be supposed to be incomplete at high temperatures, less because the steam is partially dissociated than on account of the division of the oxygen between the hydrogen and water.

[Note added June 29.—The experiments on the oxidation of ethane at so low a temperature as 300, recently described by Bone and Stockings, have shown that change proceeds with surprising rapidity in the case of mixtures containing ethane and oxygen in the ratio 2:1 or 1:1, the oxygen disappearing within thirty to forty-five minutes, whereas when sufficient oxygen was present to burn the hydrocarbon completely to steam and carbon dioxide (1:2.5), a considerable quantity of oxygen and some ethane remained unchanged even after two days. There can be little doubt, therefore, that oxygen has a specific retarding effect even at so low a temperature as 300°, and there would seem to be no reason to suppose that the changes which occur at low temperatures are in any essential respect different from those at high temperatures].

AN ACCOUNT OF SOME PHENOMENA OBSERVED DURING THE ELECTROLYSIS OF CONCENTRATED SULPHURIC ACID.

By B. G. COBB.

THE description of the phenomena here considered is the result of the work of the writer during the past year.

In the first instance, the electrolysis of concentrated H_2SO_4 appeared to offer a very interesting subject for investigation.

In the earlier experiments electrodes of aluminium one-sixteenth inch in thickness were employed.

A current of E.M.F. 200 volts through an external resistance of 300 ohms was employed.

On switching on the current, the resistance of the acid was practically nil, but it soon rose, so that after half a minute only 0.02 ampère was passing.

The cause of this appears most probably to be the H_2 gas liberated from the - pole forming a non-conducting film.

The evolution of gas from the + pole was accompanied by very curious phenomena. Bubbles of gas appeared to dart all over the surface of the electrode.

On placing the apparatus in the dark the disengagement of gas was accompanied by very vigorous sparking beneath the liquid.

These sparks worked up and down the electrode with

regularity, until after ten minutes they occupied the whole surface.

An increase in the ampère caused the sparks to show greater activity.

After two hours thirty-five minutes resistance was such that E.M.F. was only 15 volts. The sparking was, however, quite as vigorous.

After protracted passage of the current the liquid became turbid with the separation of Al_2O_3 , $\text{Al}_2\text{O}_3 \cdot \text{Al}_2(\text{SO}_4)_3$, and free sulphur, caused presumably by the reduction of the acid.

Capillary action took place on the +, i.e., the sparking electrode, and it was observed that the sparks were quite as vigorous right outside the liquid, where the surface was wet, as underneath.

If the origin of the sparks was that the current was trying to pass from the anode through the liquid to the cathode, and (finding a non-conducting film of Al_2O_3) was temporarily interrupted, why should it prefer to spark above the liquid rather than to take the path of least resistance, i.e., straight down the electrode?

The + electrode before action weighed 4.40082 grms., and after fifteen hours 4.49901 grms.

If a large current of 10 ampères be employed and the electrolyte kept cool, SO_3 is disengaged.

The current is, therefore, sufficiently powerful to overcome the great molecular attraction between SO_3 and H_2O . The presence of 0.05 per cent of water completely stopped sparking.

In using Pt electrodes no sparks are produced, but abundance of O_3 is liberated from the +, and a reddish-brown amorphous mass is formed on the - electrode.

Electrodes of pure electrolytic copper gave blood-red sparks after 2.5 hours.

(Syphon filled with acid.)

With a silver electrode for the + no sparks are noticed, but a black sticky mass (Ag_2O_2 , or $\text{Ag}_4\text{O}_?$) is produced.

Using Al electrodes and $\text{H}_2\text{S}_2\text{O}_7$, SO_3 is disengaged in the cold, but after fourteen minutes sparks cease entirely, thus differing from H_2SO_4 . Spectrum of sparks showed a line in the green of about 5200 wave-length. Voltage goes down for three hours, when it shows 6 volts, but later it rises to 16 volts, where it remains.

The addition of a small quantity of HNO_3 stops sparking temporarily, but it is soon resumed. On agitation of the liquid the sparks again cease. Ten days after an experiment, a beaker containing electrolysed acid, but from which the electrode had been removed, was found to evolve H_2S .

Al with Si dissolved showed no increase of sparking.

To some H_2SO_4 , $\text{K}_2\text{Mn}_2\text{O}_8$ was added, and the resulting Mn_2O_7 electrolysed. Sparking was then more vigorous, and after twelve hours liquid was colourless.

A solution of $\text{K}_2\text{Cr}_2\text{O}_7$ in H_2SO_4 gave more vigorous sparks, and proved an excellent conductor.

After three hours sparks had ceased. They then reappeared, but on agitation ceased. (cf. HNO_3).

An experiment with the apparatus represented above showed, with a solution of $\text{K}_2\text{Cr}_2\text{O}_7$ in H_2SO_4 , a reduction to $\text{Cr}_2(\text{SO}_4)_3$ in the cell evolving O_2 .

An extraordinary effect is produced as follows:—

If a dry glass rod be caused to touch the top of the electrode + during electrolysis, an arc is produced under the liquid between the Al plate and the glass rod held in the hand.

In view of this the following experiment was devised:—

The - electrode was an Al plate and the + a stout Al wire wound round with glass-wool. On passing the current an arc starts between the + electrode and the glass-wool beneath the surface. A quantitative analysis of the aluminium used gave as a mean of six experiments:—

Aluminium	98.53451 per cent
Sulphur	1.44316 "
Insoluble residue	0.02233 "

June 26, 1904.

ON A NEW METHOD FOR THE PREPARATION OF PURE IODINE.*

By LANCELOT W. ANDREWS.

THE impurities to be looked for in iodine are moisture, hydriodic acid, bromine, chlorine, and cyanogen iodide. A number of processes have been suggested for obtaining a product free from these contaminations, among which may be mentioned the methods of Stas ("Nouvelles Recherches sur les Lois des Proportions Chimiques," p. 136), Wittstein (*Dingler's Poly. Journ.*, 1871, cc., 310), Mohr ("Titrimethode," 1874, p. 269), Meineke (*Chem. Zeit.*, 1892, xvi., 1219), and of Lean and Whatmough (*Journ. Chem. Soc.*, 1898, lxxiii., 148). All these methods are either very elaborate, demanding no inconsiderable sacrifice of time, or like the simple re-sublimation of iodine with potassium iodide, are inefficient. The reaction between fused potassium pyrochromate and potassium iodide, which occurs in accordance with the equation—

seemed to offer a possible and simple method for obtaining pure iodine directly from the impure iodide. A preliminary experiment showed that by fusing a mixture of 29.5 grms. of potassium pyrochromate with 20 grms. of potassium iodide, practically the whole of the iodine was obtained in the free state. No iodine was set free on fusing a mixture of normal potassium chromate and iodide. A mixture of potassium bromide (6 mols.) with pyrochromate (5 mols.) furnished, on fusion, a trace of free bromine, but when to the same mixture a little normal potassium chromate had been added, no bromine was set free. It should be said that all mixtures were made by rubbing the constituents thoroughly together in a mortar.

These experiments made it appear almost certain that if potassium iodide and pyrochromate were mixed together, with the former in moderate excess of the amount required by the equation, a product free from bromine and chlorine would be assured. Accordingly, 28 grms. of potassium pyrochromate were powdered with 20 grms. of potassium iodide and 1 gm. of potassium bromide, and the mixture was fused in a wide glass tube. Three and eight-tenths grms. of the sublimate were tested in the following manner for bromine:—The iodine was thrown into 100 c.c. of hot concentrated ammonia and a slight excess of silver carbonate was added, and the solution filtered. From the filtrate the silver was precipitated by hydrogen sulphide, and the liquid boiled down to a very small bulk with a little pure barium carbonate. The residue gave no reaction for bromine, either by the fluorescein test or on spectroscopic examination according to Lecoq de Boisbaudran (*Comptes Rendus*, 1881, xci., 902).†

To summarise, the following are the necessary steps in the preparation of pure iodine by the method given:—Pulverise potassium iodide with one and four-tenths times its weight of potassium pyrochromate, each salt having been previously separately fused to insure perfect dryness. Introduce the thoroughly incorporated mixture into a wide tube, closed at one end, and heat to about 200° in a current of dry air to expel any moisture which may have been taken up during the pulverisation. Place a plug of dry glass-wool over the mixture, and wipe out carefully the interior of the tube above the plug with absorbent cotton secured to a glass rod. Slip over the open end of the tube a second short one, fitting it as snugly as possible. Fix the tube at an angle with the horizontal, and heat the powder gradually with a small flame, using if necessary a screen of asbestos board. Having sublimed the iodine into the upper part of the tube, cut off the latter, when cold, at a point 2 or 3 c.m. above the glass-wool plug, or, if smaller amounts are being operated on, the tube can be melted off at the place indicated.

Chemical Laboratory, State Univ. of Iowa.

July 6, 1903.

Since sending the foregoing communication to the Editor of the *American Chemical Journal*, it has come to my knowledge through the last number of the *Centralblatt* (1903, i., 1435) that L. L. de Koninck has published in the *Bulletin de l'Académie Royale Belgique* (xvii., 15), a nearly identical method for the preparation of pure iodine. The priority, accordingly, belongs to him, but in view of the importance of the subject, it still appears worth while to publish the entirely independent confirmation of his results which my experiments afford; the more so since, so far as it is possible to judge from the abstract, his work does not directly demonstrate that the process can be so conducted as to insure the preparation of a product free from bromine.

July 25, 1903.

THE DETERMINATION OF FUSION POINTS.

By L. MAQUENNE.

THE fusing point of a substance, whether mineral or organic, is undoubtedly one of its most distinct characteristics, the same as its boiling point if it is volatile, or its rotatory point if it acts on polarised light.

All chemists are in agreement on this matter, and every one of us has had cause for regret on numerous occasions that the figures given by the earlier writers and reproduced in the older books are for the most part incorrect, sometimes by more than 100°, as in the case of leucine (E. Fischer, *Berichte*, vol. xxxiii., p. 2373).

Such errors are explained by the fact that they merely aim attached to fusion points the importance they merit; nothing, however, is more simple than to determine the fusing point of a pure substance with accuracy, when it is sufficiently stable not to undergo any decomposition at the temperature at which its change of state takes place. The choice of method and the manner of heating are therefore matters of indifference; the use of the capillary tube plunging into sulphuric acid is to be recommended, both on account of the rapidity of its indications and the simplicity of the materials necessary.

But the same is not the case when we have to deal with a substance easily decomposed; in this case the products of its decomposition mix with what remains intact of the material, and lower the fusion point by an amount which is greater as these products are more abundant. It is necessary therefore to operate as rapidly as possible.

With the object of obtaining a rapid heating we use the metallic block I described seventeen years ago, and on the subject of which in the short paper I wrote at that time, I saw no other advantage than that of doing away with the corrections necessary in the other methods (*Bull. Soc.*

* From the *American Chemical Journal*.

† Ascertained by acidifying a filtered sample with hydrochloric acid.

‡ This method rests on the observation of barium bromide lines at wave-lengths 535.8 and 520.6.

Chim., 1887, vol. xlviii., p. 771). In reality we only use it to observe instantaneous fusion points; that is to say, those effected in less than a second of heating, which cannot be done by any other arrangements.

Thus the block represents, not so much a particular apparatus as a veritable method of procedure, which, in the case of only slightly stable materials, appears to be to be infinitely superior to any other, inasmuch as it alone is capable of giving thoroughly concordant results.

This method appears still to be but slightly known, for in quite a recent paper A. Müther and M. Tollens compared the block with the capillary tube, saying that "mit dem bloc Maquenne soll man ähnlich verfahren" (with the Maquenne block we can proceed in a similar manner). We may enquire whether these authors found the same figures by both these methods, from which they conclude that the block offers no advantages (*Berichte*, vol. xxxvii., p. 313).

This is a perfectly just and logical conclusion if we use the block as an apparatus for heating slowly; it is not so, however, when used as we use it for the instantaneous determination of fusion points. I think it necessary, therefore, once for all, and in spite of all the instructions which may be given when buying one, to describe minutely the method of procedure to be followed in order to make proper use of it.

As soon as the temperature rises we throw small quantities (about a tenth of a milligram) of the body under examination on to the surface of the metal from time to time, only leaving them there for an instant until the point is reached when fusion takes place instantaneously. We then allow the temperature to fall, and we continue the same manoeuvre while this goes on.

Thus, in the case of stable bodies, after a few attempts we arrive at two points hardly differing by the fraction of a degree, at which the body fuses instantly or does not fuse at all; their mean represents the true fusing point, identical with that given by the capillary tube. In this manner pure mannite (regenerated from its hexacetine) fuses on the block in a quarter of a second at 167° , and resists indefinitely at a temperature of 166.5° ; benzoic acid fuses instantly at 121.5° and remains solid at 121° , &c. These are types of bodies having very definite fusing points.

For unstable bodies the instantaneous fusion point, determined as above, is not equal to that observed in a capillary tube; while the latter varies with the time of heating and goes lower as the time is less, the former remains fixed, and consequently appears to give a true physical constant better than the other.

Thus the block is the only apparatus which enables us to follow the progress of a decomposition at a given temperature, and at the expense of a few milligrams of material we are able to collect more observations in half-an-hour than could be effected by twenty capillary tubes.

E. Fischer has fixed three minutes as the time necessary for obtaining a fusion at 205° (uncorrected) of phenylglucosazone; this time, relatively short compared with the usual methods, corresponds to an extremely slow heating with the block, on which the fusion ought to take place in a second at most. This accounts for the differences observed by Müther and Tollens in the fusion points for this body given by different writers, G. Bertrand and others.

To give an idea of their extent I will mention a few observations made with absolutely pure phenylglucosazone, with the idea of examining the influence exercised by preliminary heating on the value of its fusion point. The temperature of the block was kept steady, and the time necessary for liquefaction noted in seconds:—

Time (secs.)	..	190	70	35	15	10	5	Instantaneous.
Temperature	..	209°	205°	210°	215°	220°	225°	230°

It is clear, from the above, that the point 205.206° , generally admitted for this substance, is by no means abso-

lute, and that it can only be looked upon as a constant if we operate always under the same conditions. This conforms absolutely with the ideas put forward by E. Fischer on this subject some long time since.

With regards to leucine (regenerated from its cupric compound) we see that it volatilises on the block, without fusing, at all temperatures below 340° ; thus it seems to be infusible at ordinary pressures, and will only melt in capillary tubes at the commencement of decomposition.

These remarks show that to define the fusion point of a substance that decomposes under the action of heat, it is indispensable to detail the circumstances under which the observation was made. This seems to us to be a habit as useful to acquire as to give the nature of the solvent, the concentration of the solution, and the temperature of the observation, when stating a rotatory power.

I may add, finally, that the determination of the instantaneous fusing point, whether obtained with the block or by any other means, no matter which, dispenses with these accessory facts, and consequently should be preferred to the ordinary so-called fusion points.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 8).

INTERNATIONAL TABLE OF ATOMIC WEIGHTS.

THE following letter has been addressed to the members of the Great International Committee on Atomic Weights:—

We feel called upon to submit the following matter to the judgment of the committee:—

As is well known, the committee was formed in order to introduce uniformity in two points: (1) the standard of atomic weights, (2) the atomic weights of the different elements.

In order to form a decision on the first point, *i.e.*, the question of whether $H=1$ or $O=16$ should be accepted as the standard, the matter was put to the vote (*Berichte*, 1900, xxxiii., II., 1878) in the year 1900, with the result that of the forty-nine members of the committee forty were in favour of $O=16$, only seven of $H=1$, and finally two were for the use of both standards. Thus it was determined by a large majority to introduce $O=16$ in future as the international basis of atomic weights.

With regard to the second point, the committee unanimously resolved to elect a special international committee to be entrusted with the yearly issue of a table of atomic weights corresponding to the latest point of view. The result of the votes (*Berichte*, 1902, xxxv., II., 4029) taken in the year 1902 was the election as members of Messrs. F. W. Clarke, Washington (President), T. E. Thorpe, London, K. Seubert, Hanover, who, we are pleased to say, were subsequently joined by M. H. Moissan, Paris (*Berichte*, 1904, xxxvii., I., 7). It is well known that this special committee has already begun its activity, and has established the atomic weights of all the elements for 1903 and 1904 with great circumspection. The committee, however, has thought fit to issue two tables of atomic weights on the basis of $O=16$ and of $H=1$.

This latter proceeding is, indeed, the cause of the present address. We have been petitioned from various quarters to protest against this, since it is clear that in this way the former abuse of two different tables of atomic weights being in use will be re-established, and the agreement on the subject of the atomic weights basis already arrived at, be brought to naught.

To begin with, we have received from the Council of the German Chemical Society the following resolution (*Berichte*, 1904, xxxvii., I., 5), passed in a sitting held on January 6th, 1904:—

"The Council deposes the Committee on Atomic Weights of the German Chemical Society to endeavour so to determine the International Committee on Atomic Weights that the continuation of two different tables of atomic weights,

based upon different units, may be put an end to as soon as possible."

Moreover, the President of the Imperial Board of Health in Berlin presented an address on this subject, dated February 23rd, 1904, to the Council of the German Chemical Society, and which was passed on by the latter to us (*Berichte*, 1904, xxxvii., 1., 999). The address reads as follows:—

"The efforts of the German Chemical Society to bring about a uniform basis for the calculation of atomic weights have lately led to the result that two tables have been suggested by the Special International Committee on Atomic Weights, consisting of Messrs. Clarke, Seubert, and Thorpe, for the year 1903 (*c.f. Berichte*, 1904, xxxvi., p. 5—10); one table calculates on the basis of oxygen = 16, the other on that of hydrogen = 1. The committee started from the consideration that the time was not yet come for a settled and formal decision on the fundamental question of the basis of atomic weights, and that it must be left to a future development to decide which of the two standards is the more suitable.

In the same way the committee for the year 1904, which has in the meantime been joined by M. Moissan, has again published two tables of atomic weights (*c.f. Berichte*, 1904, xxxvii., p. 7—10). This issue, although only a temporary one, by no means fulfils the expectations which induced the investigations of the unit of atomic weights, and which, above all, aimed at the agreement of a common obligatory unit for all chemists.

The problem seemed about to be solved when the Committee on Atomic Weights, chosen at the incitement of the Imperial Board of Health by the German Chemical Society on December 1st, 1897, to which Messrs. Landolt, Ostwald, and Seubert belonged, came to a decision in favour of the oxygen basis, and proposed a table of atomic weights, the calculations being based on the atomic weight of oxygen = 16, for general use (*c.f. Berichte*, 1898, xxxi., p. 2761—2768).

A table calculated on this basis has been subsequently re-published in the reports of the German Chemical Society in the first numbers of the annual reports for 1899 and 1900, and these figures for atomic weights thus appeared certain of general acceptance.

It must, however, be attributed to the subsequent opposition to these figures raised by a number of chemists (*c.f. among others Berichte*, 1900, xxxiii., p. 1847—1883; also 1901, xxxiv., p. 4353—4384; 1902, xxxv., p. 1240, 4028—4030; 1903, xxxvi., p. 3759—3766) that in the year 1901 the figures relating to hydrogen = 1 were also added to the table of atomic weights of the German Chemical Society, under the name of "didactic atomic weights." As has been already mentioned, the principal point of the matter was then left undecided by the special International Committee on Atomic Weights, and the solution of the problem put off to a later time (*c.f. Berichte*, 1903, xxxvi., p. 5—10).

I shall not here enter into the scientific arguments brought forward for and against the basis of oxygen = 16, but shall only briefly point out what confusions must follow if in future both tables are to remain in use, and that it is necessary for practical reasons to form a decision on the choice of the unit of atomic weights as speedily as possible.

Whereas a number of manuals of chemistry published within the last few years have accepted the oxygen basis of atomic weights, we find in others the atomic weights based upon hydrogen = 1. Thus even the students of chemistry are in danger of becoming accustomed to the use of different tables, by which the possibility of an agreement is even further deferred.

Should both tables remain in use in future, confusions and mistakes in analytic work will be unavoidable. With respect to this we need only point out that it may, under certain conditions, be impossible to learn the true contents of a solution, if this be only given, in the written passage in question, in gramme equivalents or in the form of

standard solutions, or that in comparing the results of different experiments a constant reduction will be necessary, if one experimenter has based his results on the unit of hydrogen, the other referring to the basis of oxygen. This would finally lead to the necessity of always ascertaining the concentrations of solutions and liquids for titration on the basis of both standards in order to avoid the difficulties mentioned. Yet this state of things must be designated as both unpractical and unscientific.

The view that the basis of oxygen is preferable to that of hydrogen appears to have spread latterly, to which fact the acceptance of this standard in a large number of manuals of chemistry bears witness. Moreover, I must add for the German Imperial Board of Health that in consequence of the resolutions of the German Committee on Atomic Weights for the year 1898, in the Pharmacopœia for the German Empire, fourth edition, 1900, which is still in force, the standard of oxygen = 16 is accepted, likewise that the "oxygen atomic weights" were recommended to the "Commission Deutscher Nahrungsmittelchemiker," the "Verein Deutscher Chemiker," and the "Verbande öffentlicher Chemiker" by the German Imperial Board of Health for their acceptance and sole use in the future. Thus the Board of Health is not in a position to give up the "oxygen atomic weights" without contradicting its former instructions, especially as in all probability the present regulations of the German Pharmacopœia will remain in force until 1910.

I therefore venture to recommend to the notice of the Council of the German Chemical Society that the German Chemical Society might perhaps succeed in a second attempt to establish uniformity among chemists with respect to the basis of atomic weights, and to bring the standard of oxygen = 16 into general use.

(Signed) KÖHLER.

In consideration of the above address we are now induced to obtain the opinion of the general committee on this subject, and to beg them to decide whether the following proposal shall be made to the special committee.

The Special Committee on Atomic Weights is requested for the future—

- (a) To issue only one table of atomic weights;
- (b) To choose the one based upon O = 16.

We venture to add the following remarks.

The proposal corresponds to the resolution of the general committee of the year 1900. The reasons which then determined the majority of the members to favour the oxygen basis will be found in their written answer (*Berichte*, 1900, xxxiii., II., p. 1851—1877) to our interrogation on March 30th, 1899. As we have frequently shown in former publications (*Berichte*, 1898, xxxi., III., 2761—2768; 1900, xxxiii., II., 1878—1881; xxxvi., III.), these are based chiefly upon the fact that, as is well known, the determination of atomic weights was always first attempted in relation to oxygen (Berzelius, Stas, Marignac), the figures relating to H = 1 being calculated from the former by means of the relationship, ascertained by experiment, of O : H. After the figures 15.96 : 1, which were formerly used, had been proved to be too high, the value of 15.879 ascertained by Morley was substituted, and this (15.88) was made use of by the International Committee on Atomic Weights in drawing up the table based upon H = 1.

The hope has been expressed that the figures ascertained with the greatest care by Morley will probably undergo no more changes in future, and therefore the reduction of atomic weights from the basis O = 16 to that of H = 1 be ensured. Nevertheless, we must conclude this question not to be entirely settled yet from the calculations (*Proc. Royal Society*, 1904, lxxiii., 153) published by Lord Rayleigh at the beginning of this year on the density of some gases at a low pressure. Whereas under the usual atmospheric pressure the relationship of the densities of O : H = 16 : 1.0076, it was found that in cases of extreme rarefaction, for which only Avogadro's law strictly holds good, the value of

16:10088 is assumed. If we take $H=1$ we therefore have the result $O=15.86$, and the atomic weights calculated on this basis will all be 0.13 per cent lower than those until now derived from $O=15.88$. Thus we shall find, for example, the following alterations:—

	$H=1.$		Diff.
	$O=15.88.$	$O=15.86.$	
Chlorine	35.18	35.14	0.04
Bromine	79.36	79.26	0.10
Silver	107.12	106.99	0.13
Iodine	125.90	125.74	0.16
Platinum	193.3	193.05	0.25
Uranium	236.7	236.4	0.3

The former uncertainty is therefore by no means removed, and the evil of atomic weights which have been established with the greatest care in relation to oxygen being deprived of their accuracy by the doubtful reduction to $H=1$ continues. If, however, we leave the former unaltered, the atomic weight of hydrogen alone is submitted to an entirely immaterial change (1.008 or 1.009), and the difficulty disappears entirely.

If some chemists, especially in Germany, still favour the former basis of $H=1$, this is due partly, as may be seen from various utterances (*Berichte*, 1900, xxxiii., II., 1853—1877; and 1903, xxxiv., III., 4354—4379), to the force of habit, partly to the fact that for the elementary teaching of chemistry it appears easier to start from the unit of hydrogen. This method is, however, also in future possible for those masters who prefer it, as in treating the theory of the derivation of atomic weights round numbers are always employed, and it is of no importance whether they refer to hydrogen or to oxygen. Later, when the methods of the exact estimation of atomic weights are entered into, it can be said that in order to establish greater accuracy the basis of oxygen with the value of $O=16$ is more reliable. A difficulty, from a didactic point of view, would not exist unless quite a different figure were to be chosen for oxygen.

Furthermore, we must oppose the view (*Berichte*, 1903, xxxvi., II., 4300), that especially the employment for some time past of the oxygen atomic weights for the calculation of the physical constants in which molecular weight is concerned, has determined physical chemists to strive for the general acceptance of the former. Had cogent reasons ever been brought forward to prove the greater trustworthiness of the hydrogen atomic weights, we should never have shrunk from reducing these constants to the other standard.

After the above discussions it is impossible to doubt that in the case of a choice between the oxygen and hydrogen tables, the preference must be accorded unconditionally to that of oxygen. This view has spread continually during later years. In most of the new chemical works (c.f. a list in the *Berichte*, 1903, xxxvi., III., 3764) belonging to various countries we find that the oxygen atomic weights have been adopted, and this is also the case in almost all the modern experimental work in inorganic and physical chemistry.

We have finally to discuss the question whether special reasons exist, making it appear desirable to publish the table based upon hydrogen as well as the one based upon oxygen, as the special committee has until now done. The latter have accounted for their mode of action in the following words (*Berichte*, 1903, xxxvi., I., 6):—

"It appears impracticable to form a definite and formal decision on the fundamental question of the basis of atomic weights. The Committee on Atomic Weights of the German Chemical Society had decided, it is true, in favour of the oxygen standard, but this proposal was met with both lively support and serious opposition. Indeed, on counting the votes it would seem that the opinions on this subject are pretty equally divided between 'pros' and 'cons,' and already polemic literature to an almost alarming extent has appeared on the question. Therefore it appears impossible

to accept one of the two standards, oxygen or hydrogen, and for the present both will still remain in use. Here experience must decide, finally the standard which most uniformly fulfils the demands of chemical and physical investigation will remain victorious, while the other will gradually fall into disuse."

In answer to this we may remark that not only did the Committee on Atomic Weights of the German Chemical Society accept the oxygen standard, but, as already mentioned, the Great International Committee also declared in favour of it, after putting it to the vote in 1900, by a large majority (forty votes for O, seven votes for H). If later (1901) a number of German chemists supported the hydrogen basis (*Berichte*, 1901, xxxiv., III., 4354—4379), thus changing the proportion to seventy-eight votes for O and hundred and six for H, this result was extremely defective, since the opinions of the chemists not included in the International Committee belonging to all the other countries were entirely wanting. No one can say what the result would have been had the other countries shown as lively an interest in the question as Germany. In consideration of this uncertain state of affairs, it is clear that the decision of the Great International Committee alone can come into question (we have already discussed this matter in the *Berichte*, 1903, xxxvi., III., 3766).

We quite share the opinion that it is impossible to force the acceptance of one of the two standards. But, on the other hand, the evil consequences resulting from the existence of two tables of atomic weight can be discussed. One of these is that all the molecular weights will differ, and consequently also the physical and chemical constants derived from them, which may lead to most prejudicial confusions. Secondly, the meaning of the standard solutions will be uncertain, and it will be necessary to add to the statement of every titre to which standard of atomic weights it refers. We shall have two systems of liquids for titration, which, if not carefully kept apart, but by mistake used together, would lead to the most incorrect results. As long as there are two tables included in manuals of chemistry, partly the one and partly the other will be adopted by the different chemists, and it is impossible to foresee an end to the confusion. The hope of one of the tables disappearing of its own accord can never be fulfilled, if the chemists are still presented with the publication of both tables by the International Committee.

Based upon the above arguments we finally repeat our former question, whether the members of the Great International Committee agree to a petition to the Special Committee in future only to issue one table of atomic weights, and to let it be the one based upon $O=16$. In order to save trouble in answering we enclose a formula, and beg it to be returned as soon as possible to Professor Landolt, 14, Albrechtstrasse, Berlin, N.W. 6.

Finally we have to announce the following changes in the membership of the Great International Committee. The place of the late Professor Dr. J. Wislicenus, of Leipzig, has been taken, at the proposal of the Kaiser Franz Joseph's Academy in Prague, by Professor Dr. B. Brauner of that town, to whom, as is well known, we owe the determination of the atomic weights of many rare kinds of earth. We venture to assume that the committee will approve this.

The Committee on Atomic Weights of the German Chemical Society:—

H. LANDOLT.
W. OSTWALD.
O. WALLACH.

Royal Institution.—A General Monthly Meeting of the Members of the Royal Institution was held on the 4th inst. The Duke of Northumberland, K.G., President, in the Chair. Viscountess Gort, Mr. M. H. Spielmann, and Mr. W. R. W. Sullivan were elected Members.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Ordinary Meeting, Wednesday, June 15th, 1904.

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

(Concluded from p. 211.)

126. "Differentiation of Primary, Secondary, and Tertiary Amines." (A Preliminary Note.) By JOHN JOSEPH SUDBOROUGH and HAROLD HIBBERT.

L. Meunier (*Comptes Rendus*, 1903, cxxviii., 758) has shown that primary and secondary amines react with magnesium methyl iodide in ethereal solution according to the equations $RNH_2 + CH_3 \cdot MgI = RNH \cdot MgI + CH_4$ and $RR'NH + CH_3 \cdot MgI = RR'N \cdot MgI + CH_4$.

It is now shown that with primary amines and a solution of magnesium methyl iodide, in amyl ether the reaction proceeds quantitatively in the cold, as stated by Meunier, but that when the solution is heated a second molecule of methane is set free, presumably according to the equation $RNH \cdot MgI + CH_3 \cdot MgI = RN(MgI)_2 + CH_4$.

When a secondary amine is used, only one molecule of methane is evolved for each gram-molecule of the compound, even on heating.

Tertiary amines do not evolve any gas when mixed with Grignard's reagent.

The compounds examined so far have been *p*-toluidine, *β*-naphthylamine, diphenylamine, carbazole, and dimethylaniline. It is the intention of the authors to extend the work, and on these reactions to base methods for the characterisation of amino- and imino-groups and for the estimation of the amounts of primary, secondary, and tertiary amine in a mixture.

127. "Influence of Radium Radiations on Labile Stereoisomerides." By JOHN JOSEPH SUDBOROUGH.

The relative effects of exposing labile stereoisomerides to sunlight and to radium radiations have been examined. The substances used were *allo*-cinnamic, *α*-bromo-*allo*-cinnamic, and *β*-bromo-*allo*-cinnamic acids.

It has been already shown (*Trans.*, 1903, lxxxiii., 685, 1166) that these acids are transformed to a large extent into the more stable isomerides by the action of light or heat.

Prolonged exposure in the dark to the rays from pure radium bromide (1 mg.) does not affect the melting points of the acids.

The three acids, melting respectively at 68°, 120–121°, and 159–160°, were exposed to the radiations during a period of four months: at the end of this time no change in appearance and practically no alteration in melting point could be detected; the melting points found were 68°, 118–121°, and 158–160°. Specimens of the same acids were exposed to sunlight on March 17th, and by April 7th the melting points were considerably affected. The *allo*-cinnamic acid then began to melt at 60°, the *α*-bromo-*allo*-acid at 100°, and the *β*-bromo-*allo*-acid at 145°. On June 13th, the *allo*-cinnamic acid began to melt at 60° and was nearly completely fused by 120°, although a small amount of solid still remained at 145°. The *α*-bromo-*allo*-acid began to melt at 90° and was completely fused at 105°; the *β*-*allo*-acid began to melt at 120° and was completely fused at 135°, thus indicating that the three *allo*-acids are transformed into the stable isomerides more readily under the influence of light than by prolonged exposure to radium radiations.

128. "Notes on Analytical Chemistry." By GILBERT THOMAS MORGAN.

I. The Separation of Arsenic by Distillation in Hydrogen Chloride.—A modification of Piloty and Stock's apparatus (*Ber.*, 1897, xxx., 1649) was described, in which the mixed sulphides of arsenic and antimony were distilled in a current of hydrogen chloride, so that the vapours did not

come into contact with organic matter until after passing through a cooled aqueous solution of hydrogen sulphide.

In dealing with a mixture containing arsenic in the two states of oxidation, the distillation was first carried out in hydrogen chloride, when the arsenious sulphide precipitated in the receiver represented the tervalent arsenic. On repeating the distillation of the residual liquid in a current of hydrogen chloride mixed with hydrogen sulphide, a second precipitation of arsenious sulphide was obtained, this being derived from the arsenic originally present in the quinquivalent condition.

II. The Estimation of Carbon by Oxidation with Chromic Acid.—Phosphoric acid was substituted for sulphuric or hydrochloric acid in the gravimetric estimation of carbon dioxide in native carbonates, and when these substances contained organic matter, chromic acid was subsequently added to the contents of the distilling flask and the operation repeated, the second increase in weight of the tared absorption tube being due to the oxidation of the organic carbon.

The mixture of chromic and phosphoric acids was also used in estimating the total carbon in cast-iron and ferromanganese, the employment of a non-volatile acid instead of sulphuric acid obviating the risk of carrying over acid fumes into the weighed absorption tube.

129. "Nitrogen Chlorides containing Two Halogen Atoms attached to the Nitrogen." By FREDERICK DANIEL CHATTAWAY.

Very few substituted nitrogen chlorides containing two halogen atoms attached to a single nitrogen atom have been prepared, the best known being those derived from the primary alkylamines.

Stable, well-crystallised compounds having the general formula $RSO_2 \cdot NCl_2$ are yielded by all the sulphonamides, and a few have already been described by Kastle, Keiser, and Bradley (*Amer. Chem. Journ.*, 1896, xviii., 491).

They are most easily prepared by dissolving the sulphonamides in a solution of bleaching-powder and adding acetic acid, when they separate as crystalline solids.

The dichloroaminosulphonamides are not easily hydrolysed even by boiling with water; they dissolve in caustic alkalis, apparently yielding salts of the monochlorosulphonamides, which can be re-crystallised from water. With hydrochloric acid, hydriodic acid, or alcohol, they react vigorously, the sulphonamides are regenerated, and chlorine, iodine, or ethyl hypochlorite is liberated. On heating rapidly, the dichlorosulphonamides decompose with slight explosion, whilst the tetrachlorodisulphonamides explode with great violence. This behaviour is noteworthy, as the latter compounds are the only substituted nitrogen chlorides yet prepared which detonate in a way resembling the explosion of nitrogen chloride itself.

These compounds, as well as the chlorosulphonalkylamides and the corresponding bromine derivatives, are being further studied, as they are very reactive and promise to be of considerable value in organic synthesis. Moreover, the dichlorosulphonamides are so easily prepared, crystallised, and analysed that they may prove of considerable use in the investigation of sulphonic acids.

The following compounds were described:—

Benzenesulphondichloroamide, $C_6H_5 \cdot SO_2 \cdot NCl_2$, colourless plates, m. p. 76°; *p*-toluenesulphondichloroamide, $CH_3 \cdot C_6H_4 \cdot SO_2 \cdot NCl_2$, long, four-sided prisms, m. p. 83° (Kastle, Keiser, and Bradley, *loc. cit.*); *o*-toluenesulphondichloroamide, $CH_3 \cdot C_6H_4 \cdot SO_2 \cdot NCl_2$, colourless plates, m. p. 33°; *m*-nitrobenzenesulphondichlorodiamide, $NO_2 \cdot C_6H_4 \cdot SO_2 \cdot NCl_2$, faintly yellow, six-sided plates, m. p. 121°; *o*-nitrobenzene-*p*-sulphondichloroamide, $CH_3 \cdot C_6H_4 \cdot (NO_2) \cdot SO_2 \cdot NCl_2$ (1:2:4), pale yellow, four-sided prisms, m. p. 101°; benzene-*m* disulphontetrachloroamide, $C_6H_6 \cdot (SO_2 \cdot NCl_2)_2$, colourless rhombs, m. p. 128°; naphthalene-1-sulphondichloroamide, $C_{10}H_7 \cdot SO_2 \cdot NCl_2$, pale yellow plates, m. p. 91°; naphthalene-2-sulphondichloroamide, colourless plates, m. p. 68°; naphthalene-2:7-disulphontetrachloroamide, $C_{10}H_6 \cdot (SO_2 \cdot NCl_2)_2$, clusters of colourless pyramids, m. p. 165°; anthraquinone-

2-sulphondichloroamide, $C_{14}H_7O_2 \cdot SO_2 \cdot NCl_2$, yellow plates, m. p. 177°.

130. "Sulphonphenylchloroamides and Sulphontylchloroamides." By FREDERICK DANIEL CHATTAWAY.

In a paper on the action of sodium hypochlorite on the aromatic sulphonamides, Raper, Thomson, and Cohen (*Trans.*, 1904, lxxv., 371) state that they were unable to obtain benzenesulphonphenylchloroamide, which was too unstable to be isolated in a pure state. This and other similar compounds can, however, easily be obtained if precautions are taken to avoid the presence of catalytic agents which bring about transformation. They are well-crystallised, comparatively stable substances, and show the characteristic behaviour of chloroamino-derivatives. The method of preparation and the properties of benzenesulphonphenylchloroamide and of a number of similar compounds were described.

131. "Stereoisomeric Glucoses and the Hydrolysis of Glucosidic Acetates." By EDWARD FRANKLAND ARMSTRONG and PAUL SEIDELIN ARUP.

The results obtained on hydrolysing several of the glucosidic acetates by alkali were described and discussed in the light of the evidence recently brought forward regarding the stereoisomeric glucoses. It was shown that the acetyl groups are removed with unequal readiness from the penta-acetates of glucose and galactose and from sucrose octoacetate, and with equal readiness from the tetra-acetates of the methylglucosides and galactosides. Kreman's observation (*Monatsh.*, 1902, xxiii., 479) that the two isomeric penta-acetates of glucose are hydrolysed at equal rates is confirmed.

132. "The Colouring Matter of the Flowers of *Butea frondosa*." By ARTHUR GEORGE PERKIN.

In a former communication (J. J. Hummel and A. G. Perkin, *Proc.*, 1903, xix., 134), it was considered probable that butein from *Butea frondosa* exists in a colourless as well as in a yellow form. These modifications are, however, distinct substances. The colourless compound now termed *butin*, $C_{15}H_{12}O_5$, crystallising from alcohol in colourless needles and from dilute alcohol in pale yellow needles with H_2O , melts at 224–226°. The *triacetyl* compound, $C_{15}H_9O_5(C_2H_3O)_3$, forms colourless leaflets (m. p. 123–125°), and the *bensoyl* compound, $C_{15}H_9O_5(C_6H_5O)_3$, colourless needles (m. p. 155–157°). On fusion with caustic alkali, butin gives resorcinol and protocatechuic acid, and at a lower temperature resacetophenone is also formed. By methylation, two isomeric methyl ethers, $C_{15}H_{13}O_5$, are produced: (a) yellow leaflets (m. p. 156–158°) containing a free hydroxyl group, and (b) almost colourless, flat needles (m. p. 119–121°).

Butein, $C_{15}H_{12}O_5$, orange-yellow needles (m. p. 213–215°), crystallises from dilute alcohol with H_2O ; it is obtained in small quantity together with butin from the plant, and can be prepared from butin by the action of hot dilute caustic alkali or alcoholic potassium acetate; *acetylbutein*, $C_{17}H_{15}O_5(C_2H_3O)_2$, forms pale yellow needles (m. p. 129–131°). On fusion with alkali, butein gives the same decomposition products as butin, and on methylation the same two trimethyl ethers, (a) m. p. 156–158°, and (b) m. p. 119–121°.

When digested with boiling dilute alcoholic sulphuric acid, butein is partially reconverted into butin, and by digesting the trimethyl compound (m. p. 119–121°), which is really butin methyl ether, with alcoholic potash and water, it passes into the butein methyl ether (a) (m. p. 156–158°). Again, on digesting butein methyl ether with alcoholic sulphuric acid butin methyl ether is obtained.

Butein has the constitution of a tetrahydroxybenzylideneacetophenone (chalcone):—

as proved by the synthesis of its trimethyl ether (m. p. 156–158°) by the condensation of veratric aldehyde with resacetophenone monomethyl ether.

Kostanecki and his colleagues (*Ber.*, 1904, xxvii., 784) have shown that with dilute sulphuric acid chalcone methyl ethers give the corresponding flavanone compounds, and as both butein and its methyl ether in this way yield butin and its methyl ether respectively, there can be little doubt that butin has the following constitution:—

133. "Cyanomaclurin." By ARTHUR GEORGE PERKIN. Cyanomaclurin (*Trans.*, 1895, lxvii., 937) which exists in jackwood (*Artocarpus integrifolia*) in conjunction with morin, crystallises from water in the anhydrous form, and is now shown to be isomeric with the catechins, $C_{15}H_{14}O_6$; it forms a *penta-acetyl* compound, $C_{15}H_9O_6(C_2H_3O)_5$, separating in colourless needles (m. p. 136–138°, a *pentabenzoyl* compound forming colourless prisms (m. p. 171–173°), and the azobenzene derivative—

(m. p. 245–247°), gives an *acetyl* compound melting at 209–210°. On fusion with caustic alkali, cyanomaclurin gives β -resorcylic acid (not cresorcylic acid as previously suggested) and phloroglucinol, and with pine wood and hydrochloric acid it resembles the catechins in giving the phloroglucinol reaction. With boiling dilute hydrochloric acid, a brown amorphous compound is produced; this is identical in appearance with the so-called fourth anhydride from Gambier catechin, and has the same percentage composition.

Cyanomaclurin thus appears to represent a catechin in which the catechol nucleus is replaced by resorcinol.

134. "The Determination of Acetyl Groups." By ARTHUR GEORGE PERKIN.

The substance (approximately 0.5 gm.) in 30 c.c. alcohol is distilled with 2 c.c. of sulphuric acid, a little fresh alcohol being added from time to time. The distillate is collected in standard alcoholic potash, and this is boiled in order to saponify the ethyl acetate present, the mixture being subsequently titrated with sulphuric acid. The operation is complete in about an hour and sufficiently accurate for general use. The following results have been obtained:—

	Gave acetic acid.	Theory.
Acetylalzarin	= 37.59	37.04
Acetylquercetin	= 58.44	58.59
Acetylpuropurgallin	= 62.40	61.86
Acetylcatechin (m. p. 129–130°)	= 60.18	60.00
Acetylcatechin (m. p. 158–160°)	= 60.24	60.00
Acetylbutin	= 45.60, 45.34	45.23

With acetanilide and its homologues reliable results are also obtained, employing, however, 4 c.c. of sulphuric acid, and longer distillation. Thus acetanilide itself gave acetic acid = 44.74 and 44.55 per cent, whereas theory requires 44.44. It has been previously shown that, with alcoholic potassium acetate, acetyl derivatives of the phenols evolve ethyl acetate. This process can be employed for acetyl determinations in some instances, and is still under investigation, but as yet has not been successful in all cases. By this means acetylbutin gave 45.60 (*ante*) and acetylbutin 54 per cent; in the latter case the theory requires 54.54 per cent.

135. "Note on the Catechins." By ARTHUR GEORGE PERKIN.

In a previous communication (*Trans.*, 1902, lxxxi., 1760) it was pointed out that whereas Gambier catechu contains a catechin, $C_{15}H_{14}O_6$ (m. p. 175–177°), the pentabenzoyl derivative of which melts at 151–153°, yet a

catechin, $C_{15}H_{10}O_6$, which was isolated from *Acacia catechu*, melted at $204-205^\circ$, and gave a benzoyl compound, melting at $181-183^\circ$. It is now found that the acacia catechin gives an acetyl derivative, $C_{15}H_9O_6(C_2H_3O)_2$, forming colourless needles (m. p. $158-160^\circ$), and a tetramethyl ether, $C_{15}H_{10}O_2(OCH_3)_4$, separating in colourless prisms (m. p. $152-153^\circ$). The corresponding substances from the Gambier catechin (Kostanecki and Tambor, *Ber.*, 1902, xxxv., 1867), melt at $129-130^\circ$ and at $142-143^\circ$ respectively. For acacia catechin the name "*acacatechin*" is proposed.

136. "*A Constituent of Java Indigo.*" By ARTHUR GEORGE PERKIN.

Rawson (*J. Soc. Dyers and Colourists*, 1899, xv., 129) has shown that Java indigo contains a yellow colouring matter. This substance, $C_{15}H_{10}O_6$, forms yellow needles, melts at $276-277^\circ$, and gives an acetyl compound, $C_{15}H_9O_6(C_2H_3O)_2$, which separates in colourless needles and melts, when crystallised from methyl alcohol, first at $116-120^\circ$ and subsequently at $181-182^\circ$. The colouring matter is identical with kampherol (*Trans.*, 1902, lxxxi., 587).

ROYAL DUBLIN SOCIETY.

At the final Scientific Meeting of this session, Prof. TICHBORNE read a paper "*On a General Method in Qualitative Analysis for determining the presence of an Oxide.*"

The determination of an oxide, the author said, in a mixture or by itself, was not always easy. It was, in fact, largely indicated by the negation of special reactions and by the analyst's knowledge of the special properties of the most well-known oxides.

The method proposed by the author is based upon the reaction of phenol-phthalein with acid carbonates and carbonates of the alkalis and the fact that most metallic oxides will reduce a certain proportion of the acid carbonate to the normal carbonate.

The test solutions used are—

(1) Phenolphthalein Solution.

(2) A 5 per Cent Solution of Pure Sodium Acid-carbonate in Distilled Water.—If this solution is tested with the phenol-phthalein it will probably give a faint pinkish colouration, although the carbonate may be perfectly pure. The act of dissolving it produces a slight dissociation. A few drops of normal acid are added until the solution is quite colourless when treated with phenol-phthalein. If this test solution has been laid by for some time it must be again brought to the neutral stage.

The insoluble suspected oxide may be rubbed in a mortar with the sodium acid carbonate solution and filtered, or it may be allowed to remain in contact with the solution for about two hours, occasionally shaking, and filtered. The filtrate in each case will strike a deep crimson colour with the phenol-phthalein if an oxide is present.

Almost all hydrated oxides and oxides made in the moist way decompose the sodium acid carbonate solution.

Mineral oxides, or oxides which have been ignited, with a few exceptions, behave badly in this respect.

Ferric oxide and alumina do not act, as the carbonates do not exist.

The following oxides will reduce the acid carbonate to the neutral salt of soda:—Oxides of lead, silver, bismuth, zinc (ignited and precipitated), copper, antimony, cerium, iron (other than Fe_2O_3), mercury, tin. Alumina and ferric oxide do not act.

Dr. WALTER ADENEY then made a verbal communication on the Aeration of Sea-water. A very long discussion followed which practically filled up the evening. No written paper was put in in connection with this communication.

Mr. Richard Moss was put down for what promised to be an interesting paper, but it was crushed out by the

above discussion and a communication on the "Mechanical Analysis of Soils." The title of Mr. Moss's paper was "On the State in which Helium exists in Pitch-blende."

NOTICES OF BOOKS.

The Metallurgy of Steel. By F. W. HARBORD, A.R.S.M., F.I.C. With a Section on the Mechanical Treatment of Steel, by J. W. HALL, A.M.I.C.E. With 37 Folding Plates, comprising 178 Figures, over 280 Illustrations in the text, and nearly 100 Micro-photographs of Steel Sections. The Metallurgical Series. Edited by Prof. Sir W. ROBERTS-AUSTEN, K.C.B., F.R.S. London: Charles Griffin and Co., Ltd. 1904. Pp. 758.

THE author of this ponderous volume set out with very ambitious intentions, viz., to produce a work comprising within the limits of one volume a full description of the various branches of Steel Manufacture, both from a metallurgical and an engineering standpoint, as well as to discuss the Physics and Chemistry of Steel in relation to its manufacture. The task he set himself was a heavy one, but on looking through the pages of this book we feel bound to admit that he has succeeded in achieving his object, and has given us a work that appeals alike to the Student, the Engineer, the Works Manager, and the Chemist.

The book is divided into four Sections:—(1) The Manufacture of Steel; (2) Reheating; (3) The Mechanical Treatment of Steel; and (4) Finished Steel.

The first Section, divided into twelve chapters, describes the manufacture of steel by the various known processes, not only from the practical, but also from the chemical or theoretical point of view. These processes comprise those involving the use of Bessemer converters, the Siemens open hearth, &c., and include the production of shear and crucible steels and armour plates.

Section 2, on "Reheating," is by Mr. Harbord, in conjunction with Mr. J. W. Hall, and consists of two chapters only, the first describing various reheating furnaces, and the second methods of handling material at and in these furnaces. We now come to Section 3, on the Mechanical Treatment of Steel, by Mr. J. W. Hall; this is a most important section and comprises twenty chapters, filling some 250 pages. The first matters dealt with are those connected with rolling and rolling mills; the various kinds of mills are described, and their adaptability to special kinds of work dwelt upon; while forging, compressing, tube making, and wire-drawing are each dealt with in separate chapters.

Section 4, on Finished Steel, is devoted principally to the testing of the finished article and the physical properties of finished steel. Some of the leading testing machines are described, and the influence of impurities on the mechanical properties of steel is discussed.

There is a valuable chapter on the heat treatment of steel, which has been attracting so much attention lately, especially in connection with high speed tool steels, and the methods of using, and the details of the latest forms of pyrometers are described. The microscopical examination of steel sections has also received adequate attention, and there are a number of excellent micro-photographs belonging to this branch of the subject. The index is a full one and adds to the value of this work as a book of reference.

The Elements of Chemistry. By M. M. PATTISON MUIR, M.A. London: J. and A. Churchill. 1904.

THE author of this most admirable and original text-book need have no fear that he has produced "one more illustrated catalogue of chemical odds and ends," which is

a very true description of the only class of book which was available for the use of the student of chemistry until quite recently; the marvel was under the old system that even the most promising learner ever had the perseverance to arrange and sort out the enormous mass of facts more or less baldly stated which was put before him, and to arrive at even the most primitive ideas concerning the fundamentals of the science. This state of affairs is now altogether changed, and this type of book illustrates excellently the methods which the best and most successful teachers have now adopted. The author gives us a scholarly and readable account of the principles of the science put forward in logical order and in a most characteristic manner. The facts he enumerates are quite sufficient for his purpose, and if a student works through the book, making himself practically acquainted with the more familiar compounds in the laboratory and consulting a chemical encyclopædia for the information concerning them which he cannot acquire experimentally for himself, he ought to obtain a first-rate knowledge of the subject, and to gain a very interesting insight into the philosophy of the science. One striking feature of this work, which can hardly be too highly spoken of, is the way in which the development of the science from the earliest times is put before the student in the most interesting historical notes and extracts; the author fully realises that the careful study of the steps in the development of a theory adds vastly to the ease with which a thorough understanding of that theory is acquired.

On reading down the titles of the chapters a doubt as to the convenience of the order in which the elements are taken up is bound to pass through the mind. The first elements studied in detail are very appropriately oxygen and hydrogen, then nitrogen, sulphur, potassium, sodium, and iron. Then arsenic, antimony, bismuth, tin, and the halogens are introduced, and phosphorus after a good many chapters on essentially theoretical branches of the subject. Carbon and silicon and the rest of the metals conclude the book, and the teacher would find it very difficult to alter the order successfully.

Beiträge zur Chemischen Physiologie und Pathologie. ("Contributions to Chemical Physiology and Pathology"). V. Band. 9 Hft. Braunschweig: Friedrich Vieweg und Sohn. 1904.

THE June number of these *Beiträge* contains seven articles dealing almost entirely with physiological questions of only slight chemical interest. Siegfried Rosenberg and Carl Oppenheimer have examined the resistance of genuine albumen to tryptic digestion in the animal organism, and their numerous careful experiments, which are described in detail here, go to show that such resistance does occur within the organism as well as extra corpus. C. H. Rothera writes an account of his researches on the mode of combination in which nitrogen occurs in albumen. He finds that of the total nitrogen in chitin, for instance, about 88 per cent is present as monomino and amido nitrogen, the remainder being diamino and melanine, and he has also examined the ichthyne from the eggs of *Torpedo marmorata* with the object of deciding the same question relating to its nitrogen.

Jahrbuch der Radioaktivität und Elektronik. ("Journal of Radio-activity and Electronics"). Edited by JOHANNES STARK. Leipzig: S. Hirzel. 1904.

THE time has certainly come when radio-activity is to be regarded as an independent science, which deserves a periodical of its own, and from the distinguished names upon the title-page of this Jahrbuch, which is issued with the special co-operation of Prof. H. Becquerel and Sir William Ramsay, we may safely predict that it will be a worthy predecessor of others which will, no doubt, appear in other languages. The periodical is to contain chiefly extracts which will aid in the difficult task of keeping pace

with the enormous amount of literature dealing with radio-activity which is now appearing, but room will also be found for some original reports. This first number contains an article by Stark on the "Law and Constants of Radio-activity Changes," and a translation into German of R. J. Strutt's "Study of the Radio-activity of Certain Minerals and Mineral Waters," from the *Proceedings of the Royal Society*. Also it contains numerous abstracts of the papers which have appeared on various branches of the subject, so that if, for example, an investigator wishes to know something of the present state of our knowledge as regards the spectrum of radium, reference to the article by Precht on this point will not only give him a short account of the outlines of what he wants to know, but also a complete list of the papers dealing with it which have appeared. In the bibliography at the end of the journal an additional alphabetical list of the authors' names would be a great convenience.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 24, June 13, 1904.

Atomic Weight of Nitrogen. Analysis by Weight of Nitrogen Protioxide.—Ph. A. Guye and St. Bogdan.—The authors make a series of new determinations of the atomic weight of nitrogen, which are absolutely independent of the atomic weights of the elements Cl, K, Na, Li, and C, as they believe that the errors in the values of these latter are all accumulated in the atomic weight of the nitrogen. The experiment consists in finding the atomic weight of nitrogen relative to oxygen by an analysis of nitrogen protioxide without assuming any other atomic weights. As a mean of the numbers found, the value 14.007 may be considered as definite. The value found by physico-chemical methods being 14.002, it may be assumed that the actual value is at least below 14.01.

Decomposition of a Mixture of Calcium Carbonate and an Alkaline Carbonate under the Action of Heat in a Vacuum.—P. Lebeau.—The decomposition of mixtures of calcium carbonate with carbonates of caesium, rubidium, potassium, and sodium can be completely effected under the action of heat in a vacuum at a temperature near 1000°. This decomposition is more easily produced in the mixture than in calcium carbonate alone, and from the beginning of the dissociation the tension is decidedly inferior to that of this compound alone for the same temperature. This fact is in accordance with the existence of double carbonates of calcium and the alkaline metal possessing different dissociation temperatures.

Cuprous Salts.—A. Joannis.—The author proved in a former research that certain cuprous salts can be combined with carbonic oxide or with ammonia, and he prepared the sulphate $\text{SO}_4\text{Cu}_2 \cdot 2\text{CO} \cdot \text{H}_2\text{O}$. Since then he obtains analogous compounds by a new method, in which liquids which are very unstable in air can be evaporated in an atmosphere of carbonic oxide. The method consists in dissolving an ammonium salt in liquefied ammonia gas and allowing this solution to act on the red sub-oxide of copper. The following reaction takes place:— $2(\text{A} \cdot \text{NH}_4) + \text{Cu}_2\text{O} = \text{A}_2\text{Cu}_2 + 2\text{NH}_3 + \text{H}_2\text{O}$; A denoting a radical. The water and ammonia thus set free can combine or not with the salt formed. He applies this method to various mineral and organic salts, and by a slight modification applies it also to ammoniacal salts which are insoluble in liquefied ammonia.

A Basic Ferric Phosphate.—E. Berger.—Freshly precipitated hydrated sesquioxide of iron dissolves in an

excess of phosphorous acid. This solution is completely precipitated by water in excess, giving a white precipitate. This precipitate when not thoroughly washed has a variable composition intermediate between that of an acid and neutral phosphate. When, however, the precipitate is washed with cold water for several hours until the water is perfectly neutral, and the residue then dried first on a porous tile, then for several days *in vacuo* over sulphuric acid, a white powder of absolutely definite composition is produced. This is a basic ferric phosphate, and has probably the composition $(\text{PO}_3\text{H})_6\text{Fe}_4\cdot\text{Fe}(\text{OH})_3\cdot 5\text{H}_2\text{O}$.

Alloys of Aluminium with Bismuth and Magnesium.—Hector Pecheux.—The author succeeds in uniting the two metals bismuth and aluminium by melting them in a crucible in which the aluminium (melting at 550°) is first thrown, and then the bismuth (melting at 260°). Four homogeneous alloys are formed containing 75, 85, 88, and 94 per cent of aluminium. He also finds that aluminium and magnesium can be made to unite by maintaining the magnesium (melting at 450°) in the middle of the aluminium. Five definite alloys are thus obtained containing 66, 68, 73, 77, and 85 per cent of aluminium.

Iodine Compounds obtained with Metanitriline.—P. Brenans.—The author prepares iodine-nitrilines, and establishes their constitution by transforming them into iodo-nitrobenzene, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot 1\cdot 1\cdot 4$. He compares this compound with its isomer, $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot 1\cdot 1\cdot 4$, which is prepared by substituting the iodine of the NH_2 group in paranitriline, $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2\cdot 1\cdot 4$, and establishes the fact that the two bodies from these two origins are absolutely identical.

A Product of the Spontaneous Alteration of Oxalacetic Ether.—L. J. Simon.—Oxalacetic ether, $\text{CO}_2\text{C}_2\text{H}_5\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CO}_2\text{C}_2\text{H}_5$, when kept for some time, undergoes a spontaneous alteration which shows itself by the violet colour which it takes in contact with alkaline reagents. This alteration can be adapted to a method of identification of the ether. It is really due to the formation of a dioxiquinonic derivative.

Rosaniline Polyacids.—Jules Schmidlin.—The author's researches are to discover which are the polyacids of rosaniline. The chlorhydrates which he obtains are very stable, and their preparation is based on the fact that the brown bodies described by Hofmann retain the acid in a state of solution. It is necessary to put these bodies in a vacuum for a month in presence of potash in order to completely remove the excess of acid. The brown crystalline mass then becomes completely black and odourless.

Analysis of Commercial Nickel.—A. Hollard.—Already inserted in full.

The Composition of Gelatin rendered Insoluble by the Salts of Sesquioxide of Chromium, and the Theory of the Action of Light on Gelatin treated with Metallic Chromates.—A. L. Lumière and A. Seyewetz.—At the close of a long paper the authors arrive at several conclusions:—1. In the treatment with salts of chromium, the gelatin seems to fix the chromium directly, since its properties undergo profound modifications, and the chromium cannot be removed by numerous washings with boiling water. 2. The acid salt of chromium, although retained strongly by the gelatin, does not seem to have anything to do with the phenomenon of insolubilisation, since it can be removed without modifying the properties of the insolubilised gelatin. 3. A determined weight of gelatin fixes a constant maximum quantity of sesquioxide of chromium comprised between $3\cdot 2$ grms. and $3\cdot 5$ grms. per 100 grms. of gelatin, no matter what chromic salt be used for the insolubilisation; this seems to show that we

have to do with a perfectly definite compound. 4. On account of its easy dissociability, insolubilised gelatin is rather a compound of addition than a true combination. 5. The dissociation of chromised gelatin by repeated treatments with boiling water can be prevented, either by washing the gelatin treated with the chromium compound in ammoniacal water under suitable conditions, or by adding to the gelatin, before the addition of the chromium salt, the theoretical amount of ammonia to saturate the acid in this salt.

No. 23.

On the Hausmannites from Sweden.—A. Gorgeu.—Already inserted in full.

A Series of Artificial Quadratic Spinel of the Hausmannite Type.—A. Gorgeu.—The object of this paper was to make known a series of anhydrous saline oxides, of which pure hausmannite is the type, and which are crystallised in the same form in octahedra on a square base. The author has already thrown doubts on the existence of the sesquioxide of manganese as an acid element in the superoxides, because they are decomposed by nitric acid into the protoxide and the insoluble binioxide. However, he has repeated his experiments on the natural and artificial superoxides of manganese, but he used acetic acid diluted with from 3 to 10 volumes of water. Under these new conditions the composition of acerdes was not changed, and the same was the case when he submitted to the same treatment the anhydrous sesquioxides resulting from the prolonged calcination of acerdes or pyrolusite at a dull red heat. Treated in the same manner, hausmannite only gave up a third of its manganese in the form of manganous acetate, the insoluble portion containing the other two-thirds in the form of M_2O_3 . The author goes on to deal with the artificial hausmannites in which a portion of the manganese, viz., the manganous oxide, is replaced by another metallic oxide. He has succeeded in producing them in the case of zinc, magnesium, and cadmium, and gives analyses of these bodies. The examination of these results shows clearly that there is really a partial substitution, and that in the two latter cases especially, they represent the sesquimanganites of the form $\text{Mn}_2\text{O}_3\text{RO}$.

The Volcanic Ash from Mont Pelée, Martinique.—A. B. Griffiths.—Already inserted.

Derivatives of Lauric Acid.—G. Guérin.—The substance chosen by the author for the preparation of his lauric acid was a product obtained during the purification of oil of coco to extract the butter. It was first saponified and then treated with an excess of hydrochloric acid, and heated; the fatty acids were decanted, dissolved in ether, and distilled; the residue was then digested with an equal weight of pure methylic alcohol, and half that quantity of sulphuric acid for six hours to produce etherification. The cooled product was poured into a large quantity of water, the upper portion decanted and washed with 10 per cent carbonate of soda and distilled water, then dried completely. These methylic ethers were then distilled fractionally, and the products collected at every 5° . The first portions came over at 95° , the last at 275° . The lower fractions appeared to contain small quantities of capric acid, then he found caprylic acid, and the higher fractions corresponded to myristic, palmitic, and stearic acids. As for the fraction corresponding to lauric acid, it represented about 65 per cent of the ethers. The author then describes in detail the isolation of the caprylic acid, the preparation of lauric acid, lauro-orthotoluide, lauro-paratoluide, lauro-phenylhydrazide, chloride of lauryl, and bromolauric acid.

α -Hydroxylauric Acid, $\text{C}_9\text{H}_{19}\cdot\text{CH}_2\cdot\text{CHOH}\cdot\text{COOH}$.—G. Guérin.—This acid is prepared by placing 200 grms. of bromolauric acid in a porcelain crucible with 125 grms. of potassic hydrate and about 2 litres of water. Boil for two or three hours, keeping the volume constant; then cool. The alkaline solution of hydroxylaurate is then decomposed with hydrochloric acid in excess, and taken

up with ether; this latter is washed, decanted, and evaporated. The residue, dried at 100° *in vacuo*, is redissolved in chloroform, from which it is crystallised by cooling in ice. The crystals of hydroxylauric acid fuse at $73-74^{\circ}$. The author describes the preparation of several salts of this acid, such as the hydroxylaurate of sodium, potassium, copper, and lead, as well as its ethers and amides.

Undecylmethylketone.—G. Guérin.—This substance is prepared by reacting with 14.25 grms. of sodium wire on 80 grms. of acetylacetate of ethyl, previously diluted with 250 grms. of anhydrous ether; the reaction is a very lively one, and the flask must be kept cool. After about twenty-four hours, all the sodium has disappeared forming, acetylacetate of ethyl-soda, which is precipitated as a white mass. At this moment 100 grms. of chloride of lauryl are run in, and the whole is heated on the water-bath. After eight hours, cool, and treat the mass with a large excess of water. Add ether, wash and separate the ethereal layer, which is dried and distilled. The residue consists of a mixture of the O-ether and the C-ether, and weighs 140 grms., a return of 98 per cent. This product was saponified directly; the methylundecylketone formed, purified by crystallisation in methylic alcohol, fuses at 28° , and boils at $140-142^{\circ}$ under 14-15 m.m.

Transformation of Benzophenone into Triphenylcarbinol.—R. Delange.—If 100 grms. of benzophenone are mixed with the same weight of finely-powdered, dry potash, and heated to 170° for about twenty hours, about 15 or 16 grms. of benzene are collected on distillation. The contents of the flask, taken up with water, give an alkaline liquid which gives 45 grms. of benzoic acid by acidification with a dilute acid. Now, if the above alkaline liquor is washed with ether before the addition of the dilute acid, an ethereal solution is formed, which on evaporation leaves 25 grms. of a solid product. After crystallisation in alcohol at 80° , this compound fuses at 159° , and possesses all the properties of triphenylcarbinol.

Am. Chem. Soc.*, 1897, xix., 657; *Ibid.*, 1899, xxi., 1017; Thomas, *Journ. Am. Chem. Soc.*, 1899, xxi., 373; Taylor, Thesis, University of Pennsylvania, 1901.

The literature pertaining to this subject covers a period of nearly three-quarters of a century. Eight different methods have been used in striving to solve the problem. They are:—

1. Reduction of Tungsten Trioxide.—Berzelius, 2; Schneider, 5; Marchand, 2; Borch, 7; Dumas, 8; Bernoulli, 6; Persoz, 2; Roscoe, 3; Waddell, 5; Schneider, 3; Shinn, 4; Hardin, 29. A total of 78 reductions.
2. Oxidation of Metal.—Schneider, 3; Marchand, 2; Borch, 2; Bernoulli, 4; Roscoe, 2; Pennington and Smith, 9; Schneider, 3; Hardin, 37. A total of 62 oxidations.
3. Weighing the Water from the Reduction of Trioxide.—Riche, 2; Smith and Desi, 6.
4. Determination of the Water Content of Barium Metatungstate.—Scheibler, 5; Hardin, 2.
5. Analysis of Tungsten Hexachloride.—Roscoe, 2.
6. Analysis of Iron Tungstate.—Zettnow, 4.
7. Analysis of Silver Tungstate.—Zettnow.
8. Determination of the Water in Sodium Tungstate.—Thomas, 22.

The results obtained by the first and second methods are the most numerous. The frequent employment of these methods would indicate the opinion to be general that they are the most rational. This they are, notwithstanding the want of concordance evident in the work of all chemists who have pursued either one of these methods in the attempt to solve the existing problem. Their sufficiency has been doubted, especially by Hardin, working in this laboratory. He was disposed to attribute the lack of agreement in his work to volatilisation of substance, both in the experiments of reduction of trioxide and in those in which the metal had been oxidised. Hardin adopted the method of purification pursued by Pennington and Smith, and therefore believed that the material with which he operated was pure; hence the errors were the result of imperfections in the method employed.

Pennington and Smith, cognisant of the presence of molybdenum in the tungsten compounds, confirmed by numerous observations of others, were induced to undertake a solution of the difficulty surrounding the atomic weight of tungsten because they noticed in Schneider's communication, that when he reduced tungsten trioxide in a

current of hydrogen "ein weissliches Sublimat" appeared on the anterior portion of the reduction tube, which sublimate Schneider thought was tungsten chloride, but which Pennington and Smith, in the light of the discovery of molybdenum in all tungstates, believed was due to the latter element. They accordingly purified a portion of tungsten trioxide by the plan recommended by Schneider, and, after eliminating any possible molybdenum content, made tungsten metal and oxidised it. They gave as a result of their labours probably the most concordant series of figures ever published for the constant in question. The other striking feature of this series was their high value, namely, 184.92. This was much higher than that generally considered to be the correct value. Its rise was supposed to be due to the complete removal of molybdenum. Let it be noted that Pennington and Smith used tungsten metal from trioxide reduced in a crucible of platinum, and further that they used the second method only.

The work of Smith and Desi, who used the third method, apparently confirmed the conclusions of Pennington and Smith. It may be said that the early work of Schneider, leading to the value 184, had been practically confirmed by subsequent investigators, so that the constant 184 had been looked upon for a period of forty-five years as the accepted atomic weight of tungsten. The experiments of Pennington, Smith, and Desi could not fail to be regarded with some question notwithstanding the evident care exercised by them in preparing suitable material for their respective studies, and the conscientiousness to detail exhibited in the experimental work. Schneider was still living on the appearance of the communications just referred to, and in letters to one of us, as well as in a public print, naturally took exception, in the most courteous manner, to the methods and to the conclusions of those who advocated the higher value (184.92). It is not necessary here to enter into a detailed review of Schneider's second and later paper. Briefly, he very much doubted whether it was the complete removal of any molybdenum content from the tungstic acid which occasioned the rise in the atomic number. He also entertained grave doubts as to whether, in the methods employed, there were not sources of error which escaped these chemists. The small quantities of material used by Pennington, Smith, and Desi were, in the opinion of Schneider, contributory sources of error.

The problem, attracting new attention to itself in this laboratory, led to further studies upon this subject, chief among which were the painstaking investigations of Hardin, extending over several years. Reference to these will show that few points of inquiry escaped this investigator, and one can readily comprehend the spirit which prompted him to say in his final contribution on this subject:—

"So far as known there is no perfectly reliable method for the determination of this constant. The method of reduction and oxidation is probably more accurate than any of the other methods which have been employed. The results obtained by it vary about one unit and even more in exceptional cases."

In our frequent discussions on this topic, it did seem as if search for new methods was absolutely required; that these alone might be expected to settle the difficulty once for all. Taylor, engaged at the time in this laboratory upon the ammonium tungstates, noticed that ignited tungsten trioxide, when dissolved in a solution of pure sodium carbonate, left a white flocculent residue. When dissolved in potassium hydroxide, this residue was not so evident, and in his thesis (University of Pennsylvania, 1901) he continues:—

"On standing a few hours in sodium carbonate, this residue turned reddish-brown. On treatment with hot concentrated hydrochloric acid, it (having been previously washed) broke down into tungstic acid, and the filtrate contained the chlorides of iron and manganese. To ascertain if the original ammonium tungstate would reveal the presence of these impurities, it was dissolved in water, feebly acidulated with hydrochloric acid, and ammonium sulphocyanate added. No coloration was produced.

* From *Proceedings of the American Philosophical Society*, vol. xliii., No. 176.

Another portion of the solution was boiled with hydrochloric acid, the tungstic acid precipitated, and now the filtrate easily showed the presence of iron.

"The residue, insoluble in sodium carbonate, appears to be a tungstate of iron and manganese, which probably existed in the ammonium salt, as an ammonium iron-manganese tungstate. Laurent states that the mother-liquor from ammonium tungstate contains such a salt (*Journ. Prakt. Chem.*, 1847, xlii., 126). He ascribed to it the formula $12(\text{NH}_4)_2\text{O} \cdot 6\text{MnO}_2 \cdot 2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O} \cdot 45\text{WO}_3 \cdot 8\text{H}_2\text{O}$ (*Comptes Rendus*, 1850, xxxi., 693).

"Borch analysed this salt with the following results (*Journ. Prakt. Chem.*, 1851, liv., 254):— WO_3 84.4 per cent, $(\text{Fe}_2\text{O}_3 + \text{Mn}_2\text{O}_3)$ 4.6 per cent, NH_3 4.0 per cent, H_2O 7 per cent. Laurent states that this complex salt is soluble in water and ammonia, and is peculiar in that ordinary reagents do not show the presence of iron, manganese, or tungstic acid; further, that the salt is only broken down by prolonged boiling in acids or alkalis, and then the ingredients can be readily detected.

"Schneider recognised the presence of this salt in ammonium tungstate, and stated that it was not removed after five or six re-crystallisations (*Journ. Prakt. Chem.*, 1850, l., 152). Also that it could not be removed by the ammonium sulphide treatment, for slight amounts of the sulphides of iron and manganese are soluble in the tungsten sulpho-salt. Berzelius stated that the sulphides of tungsten, iron, and manganese form a compound which is partly soluble in water (*Pogg. Ann.*, 1826, viii., 279).

"To remove this complex salt, Schneider purified his material in the following way:—Tungstic acid, obtained from the sulpho-salt of tungsten, was boiled in aqua regia, and washed in acidulated water till free from iron. This was dissolved in dilute ammonia, and the solution precipitated by boiling hydrochloric acid, the resulting tungstic acid boiled in aqua regia, and again washed. This oxide was again dissolved in ammonia, and again precipitated. After re-precipitating three times in this manner, tungsten trioxide was obtained free from iron. However, on dissolving the oxide in potassium hydroxide, a slight brown residue remained which had escaped all earlier tests. This he assumed was not enough to affect the result of his work.

"Had he applied the sodium carbonate test, this residue would have been larger. In the recent repetition of his work (*Journ. Prakt. Chem.*, 1896, cli., 288), he used material purified in precisely the same manner (in fact some of the original material), with the exception of the treatment for the elimination of molybdic acid.

"Borch recognised this complex salt, and tried to remove it by fusion with potassium carbonate (*Journ. Prakt. Chem.*, 1851, liv., 254).

"Later investigators seem not to have appreciated the difficulty of eliminating it. It crystallises in part with the ammonium tungstate, and can scarcely be entirely removed by re-crystallisation. Ignition of the ammonium salt, and resolution in ammonium hydroxide will not eliminate it. Nor will ammonium sulphide remove it. In fact, it seems likely that it has never been wholly extracted from any previous material.

"The purification by Pennington and Smith did not remove it (*Proc. Amer. Phil. Soc.*, 1894, xxxiii., 332), for though closely following the method outlined by Schneider, and adding to it the complete elimination of molybdenum, they omitted the final repeated precipitations with acid.

"To understand the effect of possible impurity, the following table is given. A molecular mixture of tungsten and the impurity is treated as though it were all tungsten, and the resulting atomic weight calculated.

Molecular mixture.	Reduction series atomic weight.	Oxidation series atomic weight.
W + W	184	184
W + Mo	140	140
W + 2Fe	148	148
W + 3MnO	298	298
Loss of material	Low	High

"A consideration of these numbers shows that molybdenum and iron would produce a low value; manganese a high value; volatility a low value on reduction, and a high value on oxidation. The error introduced by manganese is more than three times as costly as that introduced by iron, and more than two and a half times that introduced by molybdenum. These ratios would apply regardless of the proportion of the mixture.

"From these considerations it is believed, that the presence of manganese and iron will account for the high oxidation values, for their presence would affect the result in a twofold manner:—Manganese through its inherent molecular changes, $\text{Mn}_2\text{O}_3 \rightleftharpoons \text{MnO}$, and iron through its secondary action on the volatility. Further, that the presence of iron, molybdenum, manganese, and volatility will explain the numerous discrepancies noted in the published work on this subject. Again, since iron and molybdenum decrease the value, and manganese and volatility increase the value, and iron and molybdenum influence the volatility, it is quite possible that such a mixture of these factors might occur that the errors would be compensated.

"Viewed in this way there still remains the necessity for determinations with material from which every trace of molybdenum, iron, and manganese, together with other possible impurities, has been removed.

"The method of determining atomic weights from the loss of carbon dioxide has been applied to a number of the elements. Its application to tungsten, and the special modification of the method necessary for accurate determinations, has not been before recorded. Svanberg and Struve fused molybdenum trioxide with potassium carbonate and determined the loss in weight (*Journ. Prakt. Chem.*, 1848, xlv., 301). Their value is nearly six units too low, and the method must be considered inaccurate. This method was tried with tungsten trioxide, and gave values ranging from 160 to 180. The disadvantages of the method are that the union takes place with considerable spattering; the temperature of fusion is so high that loss by volatility is probable; the alkaline carbonates when held in fusion slowly lose traces of carbon dioxide; and the resulting fusion is extremely hygroscopic.

"These difficulties may be obviated by combining the oxide and sodium carbonate in aqueous solution, and then expelling the water. Operated in this manner the method possesses promising value; and has numerous advantages, among which may be mentioned that carbon dioxide has a molecular weight of forty-four, giving a value for comparison nearly as great as in the simple reduction and oxidation method; the union of sodium carbonate and tungsten trioxide in aqueous solution takes place at a low temperature, and the highest temperature used in the desiccator is a safe distance below the melting-point of sodium carbonate, so that there is little chance for volatilisation either of sodium carbonate or tungsten trioxide, and in the device used there is no chance for loss by spattering; large quantities of material may be combined with as much ease as small; the method itself would serve for a test of the purity of the material; the presence of chlorides, sulphates, sodium silicate, and potassium carbonate would not affect the result. The presence of alkaline hydroxides would; and to prevent the possibility of this, pure sodium carbonate was saturated in solution with carbon dioxide, and the resulting bicarbonate heated in a vacuum at 300° for three hours.

"The tungsten trioxide and sodium carbonate were combined in a glass bulb as in the sketch. A neutral glass is desirable for this purpose, and the bulb should be made of Jena glass, which will withstand the action of alkaline carbonates better than ordinary glass. If sodium carbonate dissolves the glass no error will be introduced, but if carbon dioxide be liberated through such solution, then the glass cannot be used. To determine this point a blank experiment was made, which showed that the total weight of the bulb and sodium carbonate remained unchanged, while 0.007 grm. of glass were dissolved; hence no appreciable evolution of carbon dioxide occurred. How-

ever, to prevent any possibility of such loss, a platinum bulb had better be used.

"It was found that moist sodium carbonate could be heated to a constant weight, by heating for one and a-half hours at a temperature of 300° in a vacuum; and in this bulb the weight after standing several days remained unchanged. To insure complete desiccation the bulb was always heated double the required length of time. A water pump was used to produce the diminished pressure, and since nothing can be perfectly dried in a vacuum resulting from such a pump, a calcium chloride tower was introduced. But calcium chloride will not perfectly desiccate a gas, so that phosphorus pentoxide had better be used. However, for the preliminary experiments in hand, calcium chloride was sufficient.

"The method of procedure was as follows:—Some sodium carbonate was introduced into the bulb and heated for three hours at 300° in a vacuum. The suction was disconnected, and after cooling, the combined weight of bulb, sodium carbonate, and dry air was obtained. Tungsten trioxide was then introduced through a long funnel, the bulb was exhausted, allowed to fill with dry air, and again weighed. This gave the weight of tungsten trioxide. The weight of the sodium carbonate, further than being present in excess, need not be known. Water was added, and the bulb heated in a glass air-bath, so that the course of the reaction could be watched. The mixture slowly effervesced, and when the action had ceased, the vacuum apparatus was attached, and the water distilled off. This water was tested and found to be neutral. The calcium chloride tower was now introduced, and the residue, consisting of a mixture of sodium tungstate and carbonate, was heated for three hours at 300° in a vacuum. After cooling, and thus allowing the bulb to fill with dry air, it was detached and weighed. This loss in weight gave the carbon dioxide evolved. It may be added that the entire bulb should be inside the air-bath, until the water has been removed; and then the upper portion be placed outside, and the temperature increased to 300° . In this way no moisture will condense in the head, and the stopper remaining perfectly dry will not become jammed. The stopper should not be lubricated.

"The following results were obtained, from impure material, which in the previous experiments in this paper gave values ranging from 182.24 to 184.82 , and which was known to contain iron, manganese, and probably molybdc acid:—

Weight of Na_2CO_3	Weight of WO_3	Weight of CO_2	Atomic weight of tungsten.
Grms.	Grms.	Grm.	
1... 2.7	2.0802	0.3952	183.60
2... 2.3	2.1937	0.4173	183.30
3... 3.5	3.0818	0.7762	183.38
4... 3.8	3.3629	0.6394	183.41

"These numbers, in that they indicate the atomic weight of tungsten, are worthless; in that they show promise for the new method, are of value. The presence of impurity would lower the result; what value the method will give for pure material can only be conjectured."

(To be continued).

THE CONSTITUTION OF THE AMMONIUM COMPOUNDS.*

By JOHN CANNELL CAIN, D.Sc., M.Sc.

THE theory of ammonium compounds, proposed by Ampère in 1816 and generally accepted even at the present time, has not, in spite of its continuance, been entirely free from attack.

The objections of Kekulé, based on his non-belief in the existence of a pentad nitrogen atom, cannot, of course, be regarded as valid to-day, as the doctrine of variable valency is everywhere accepted.

Thus Japp, in the Kekulé Memorial Lecture, 1897, says, "the doctrine . . . of fixed valency . . . is, so far as I am aware, without supporters."

We have long given up, therefore, Kekulé's molecular formula of ammonium chloride, $\text{NH}_3\cdot\text{HCl}$, although we still adhere to this method of writing a large number of so-called molecular compounds.

The difficulty of explaining the union of ammonia and hydrochloric acid in terms of the ammonium theory was raised by Chevreul, and Wurtz ("The Atomic Theory," 1880) found it hard to explain why the chlorine should give up its affinity for hydrogen, and unite with nitrogen for which it has only a slight attraction. He pointed out that, although the separation of chlorine and hydrogen should give rise to a considerable absorption of heat, and the union of chlorine and nitrogen can produce only a feeble evolution of heat, yet the formation of sal-ammoniac gives rise to a considerable evolution of heat. Wurtz's explanation of this is that "the affinity of the chlorine for hydrogen is satisfied by the attraction which it exercises upon all the atoms of hydrogen within the sphere of which it is now situated." This, however, goes beyond the confines of the valency theory. The inability of the ammonium theory to explain the extraordinary stability of tetramethyl ammonium iodide to caustic potash has been pointed out by Armstrong in 1888 (*Phil. Mag.*, [5], xcv., 21), and also in his article "Chemistry" in the *Encyclopædia Britannica*. He says, "It is highly remarkable that tetramethyl ammonium iodide should not be in the least affected by even the strongest caustic alkali, and that the halogen . . . behaves much as does that in alkylic haloids. This would seem to be a strong argument in favour of the view that the halogen is not simply associated with the nitrogen, but retained in combination with the hydrocarbon radicle." Armstrong suggested (1888) that this substance should be represented by his "residual affinity" formula—

An important objection to the ammonium theory has quite recently arisen in the existence of isomeric optically inactive organic ammonium salts. Werner (*Annalen*, 1902, cccxxi., 261) instances the two isomeric trimethyl isobutyl ammonium salts of Le Bel (*Comptes Rendus*, cx., 144), the two methyl di-ethyl amyl ammonium chlorides of Schryver (*CHEMICAL NEWS*, 1891, lxi., 174), and the ethylene propylene dipiperidinum bromides of Aschan (*Ber.*, 1899, xxxii., 988). Aschan, however, has contradicted the existence of the latter (*Ber.*, 1903, xxxvi., 1164), and the other two cases may be attributed to dimorphism (compare Jones, *Journ. Chem. Soc.*, 1903, lxxxiii., 1401).

* From the *Memoirs and Proceedings of the Manchester Literary and Philosophical Society*, 1904, xlviii., No. 14.

There are still the isomeric inactive phenyl, benzyl, allyl, methyl ammonium iodides of Wedekind (*Ber.*, 1899, xxxii., 518), one of which has been resolved into its optically active constituents by Pope and Peachey (*Journ. Chem. Soc.*, 1899, lxxv., 1127), and the several sets of isomers described by Kipping (*Journ. Chem. Soc.*, 1900, lxxvii., 861; 1901, lxxix., 430; 1903, lxxxiii., 873), which are well defined. The latter has obtained two isomers of hydriindamine bromocamphorsulphonate, chlorocamphorsulphonate, and *cis-r*-camphanate, as well as others from substituted hydriindamines, none of which contain an asymmetric nitrogen atom. The existence of such isomeric forms recalls the experiments of V. Meyer and Lecco (1876), who showed the identity of the quaternary ammonium iodides obtained from trimethylamine and ethyl iodide, and ethyl dimethylamine and methyl iodide, and concluded that this compound was properly represented by the ammonium theory, and not to be regarded as a substituted ammonia hydrochloride. This conclusion must now be doubted in view of the many cases of two isomers here quoted.

Werner proposes a new ammonium theory, which—involving as it does, such terms as “principal valency” (“hauptvalenz”), “supplementary valency” (“nebenvalenz”), and “co-ordination constant”—is apparently not very different from the older idea of molecular attraction or residual affinity. According to Werner, the formula of ammonium chloride would be $H_3N \cdots HCl$, a supplementary valency (indicated by the dotted line) existing between the nitrogen atom and the hydrogen of the hydrochloric acid—an assumption for which there is at present no experimental evidence.

The constitution which I suggest for the ammonium compounds would, I believe, account in a very simple manner for the whole of the facts referred to above, and the formulæ for ammonium chloride and ammonium hydrate would be—

in which chlorine is triad and oxygen tetrad. The statement that, in the case of a pentavalent nitrogen atom, only four valencies can attach themselves to an organic radical, the fifth being always united to a halogen or hydroxyl group (compare Vaubel, “Stereochemische Forschungen,” 1899; Wedekind, “Zur Stereochemie des fünf wertigen Stickstoffes,” 1899) is at once explained in the light of this formula. It is perhaps hardly necessary to adduce evidence in favour of the conception of triad chlorine. Thus Armstrong writes (“*Encycl. Brit.*,” *loc. cit.*):—“As it is clear that iodine may exercise triadic functions, the remaining halogens can scarcely be denied the rank of potential triads.” And, again, Ramsay says (“*Modern Chemistry*”):—“It must . . . be assumed that the halogen atoms are . . . possibly triads. The mode of combination of these double salts (*i.e.*, $ZnCl_2 \cdot 2KCl$) is possibly owing to the fact that the halogens are capable of acting as triads.” That oxygen can often become tetravalent is to-day generally accepted.

(NOTE.—Although, as I find, these formulæ occur, together with corresponding ones for tetramethylammonium iodide and tetraethylphosphonium iodide in a paper by Heyes on Valency (*Phil. Mag.*, 1888, [5], xxv., 297), yet no arguments are used in favour of them, and no further application of them is made).

The union of ammonia and hydrochloric acid is very simply explained by the equation $H_3N + ClH \rightarrow H_3N = ClH$. The influence of moisture on this combination is, in my opinion, the same as in the case of the union of carbon monoxide and oxygen where there is no question of ionisation, or possibly intermediate addition compounds are formed with water by both ammonia and hydrochloric acid. The electrolytic dissociation of sal-ammoniac and ammonium hydrate is quite in accordance with the new formula. Whereas according to the usual ammonium theory, ammonium hydrate should dissociate in the same way as potassium hydrate,—

As a matter of fact the degree of dissociation is exceedingly small, resembling that of water, and Hantzsch has shown that the dissociation takes place in the sense that water is split off (*Zeit. für Phys. Chem.*, xxx., 258). This is to be expected if we write—

The almost complete electrolytic dissociation of sal-ammoniac in dilute solution is equally well explained by both theories; thus we have—

and—

We get here a complex ion, $NH_3.H^+$, and there is, of course, no evidence as yet which can decide between the

ion NH_4^+ and the more complex one $NH_3.H^+$.

The remaining halogen salts of ammonia are analogously written, and the sulphides thus:—

My formula for ammonium hydrate, $H_3N = OH_2$, is analogous to that of water, $H_2O = OH_2$; of hydrogen peroxide, $O = OH_2$; and of ozone, $O = O = O$. The general formula for salts of ammonia and oxygen acids is $H_3N = OHX$; thus ammonium sulphate is written—

oxygen, of course, being tetrad.

The obvious question as to the possibility of this formula, in view of the isomorphism of the ammonium and potassium salts, at once arises. Ought we not, however, to expect some difference between these salts from the fact that water is always eliminated in the formation of, for instance, potassium sulphate, while no such reaction takes place in the case of ammonium sulphate? The formation of potassium sulphate may, however, be exactly analogous to that of ammonium sulphate. Thus:—

1. Addition—

2. Molecular change—

3. Water split off—

In the case of ammonium sulphate, the group attached to the tetrad oxygen atom is split off at a higher temperature.

If we have hitherto regarded as isomorphous, compounds containing two such differently constituted groups as—

can we say that the groups—

would not belong to isomorphous salts.

Lothar Meyer says (“*Outlines of Theoretical Chemistry*”) “it has been assumed that an atom of potassium can be isomorphously replaced by the ‘compound radical’ ammonium, composed of one atom of nitrogen and four atoms of hydrogen; but if this is possible in one case, it may

frequently happen that several atoms replace one single atom. If we admit this, then the whole foundation of these considerations (i.e., on isomorphism) is weakened (the italics are mine). We must also not forget that the nitrates, the bichromates, and the persulphates of potassium and ammonium are not isomorphous. There is thus no argument from the theory of isomorphism which negatives my view.

(To be continued).

ESTIMATION OF THE PERCHLORATE OF SODIUM IN COMMERCIAL NITRATE OF SODIUM.

By H. LEMAITRE.

It is the usual custom to sell nitrate of sodium for commercial uses at so much per cent of nitrate of sodium determined by difference, and at a maximum proportion of 0.37 to 0.57 of chlorine according to agreement. In the "commercial" analysis the following estimations are made:—Moisture, insoluble residue, sulphate, and chloride of sodium. No mention is made of the perchlorate or of the iodate of sodium, although seven or eight years ago the attention of chemists and manufacturers was drawn to the never negligible, and sometimes high, proportion of perchlorate (rarely iodate) present in saltpetres from Chili.

However, besides the fact that the presence of these bodies vitiates the commercial analysis, as is admitted, the perchlorate and the iodate in similar proportions are as objectionable as chloride of sodium in the principal commercial uses of the Chili nitrates.

We know that chlorine is an important factor in the destruction of the lead chambers, and, on the other hand, manufacturers of explosives who use large quantities of nitrates require nitric acid with a very small proportion of chlorine.

Therefore it would be more rational to value the chloride, perchlorate, and iodate of a saltpetre as chlorine, and also if we wish to establish the percentage of pure nitrate by difference to take note of the presence of the perchlorate and iodate.

In the meantime we give a new method for the estimation of the perchlorate.

This estimation is based on the following reaction:— $\text{ClO}_4\text{Na} + (\text{SO}_3\text{Na}_2)_1 = (\text{SO}_3\text{Na}_2)_1 + \text{NaCl}$. For a nitrate containing less than 4 per cent of perchlorate the proportions are:—

Chili saltpetre 5 grms.
Pure dry sulphite of sodium 3 "

The sulphite and the nitrate are mixed in the dry powdered state, and placed in a platinum crucible. Heat carefully until the mass is in tranquil fusion. Allow to cool, and take up with water.

The solution is then boiled, and 200 c.c. of a boiling solution of nitrate of barium at 4 per cent is poured in. The precipitate is allowed to settle, and filtered.

The solution, treated with about 8.2 c.c. of normal soda, then with 1.2 gm. of persulphate of sodium, is brought to boiling, and filtered. The clear solution, added to the wash waters, is slightly alkaline. It is neutralised exactly with a dilute solution of acetic acid, using phenolphthalein as an indicator. Titrate with N/10 nitrate of silver, using chromate of potash as the indicator.

The proportion of chlorine can be also determined by weighing the chloride of silver precipitated by the decinormal nitrate of silver.

The chlorates and iodates are equally reduced to the state of chlorides and iodides by sulphite of sodium:—

The treatment with sulphite of sodium should therefore have the result of bringing to the state of chloride and iodide all the perchlorate and iodate of sodium contained in Chili saltpetres.

The iodate can be estimated by M. Auzenat's colorimetric method (*Moniteur Scientifique*, February, 1900).

The chloride and iodate of sodium are estimated directly on the nitrate of sodium by means of an excess of decinormal solution of nitrate of silver.

It is easy then to calculate the percentage of perchlorate.

Note.—The nitrates used for the manufacture of nitric acid generally contain less than 2 per cent of perchlorate and iodate; in any case, if the estimation gives more than 4 per cent we ought to begin again on 5 grms. of the nitrate, doubling the amounts of the reagents used. Five grms. of nitrate at 4 per cent = 200 m.grms. of ClO_4Na , for which theoretically we ought to use 82.3 m.grms. of pure SO_3Na_2 . Actually we use 3 grms. of SO_3Na_2 .

Three grms. of sulphite of soda, or their equivalent in SO_3Na_2 , are precipitated by 6.214 grms. of NO Ba. We use 200 c.c. at 4 per cent, that is 8 grms. : 8 grms. : 6.214 = 1.786 of NO_3Ba , corresponding to 0.814 of SO_3Na . We use 1.2 grms. of persulphate of soda (at 71 per cent = 851 m.grms.) neutralised with 8.2 c.c. of normal NaOH:—

THE TRANSFORMATION OF THERMOCHEMICAL ENERGY INTO VOLTAIC ENERGY OR ELECTROMOTIVE FORCE.*

By D. TOMMASI.

Of late years a number of papers have been published on two-fluid batteries which exercise a reciprocal chemical action (action of a base on an acid, for example); this has rendered possible the observation that the nature of the electrodes plays a very important part in the amount of electromotive force developed by these batteries.

Thus, with uncomposable electrodes we observe that the electromotive forces of certain voltaic couples are often different from the electromotive forces calculated from the heat of the reactions, and, further, that they differ among themselves for the same liquids, according to the nature of the metals which constitute the electrodes of these couples.

These facts, though looked upon as new, were, however, observed and described by me in 1882 in a paper I presented to the Académie des Sciences, (*Comptes Rendus*, June 5, 1882) entitled "Influence of the Positive Pole of a Battery on the Quantity of Heat Transmissible to the Circuit in the form of Voltaic Energy."

In this paper I remarked that, contrary to the accepted opinion, the electromotive force of a definite voltaic couple varies according to whether its positive electrode consists of an unattainable metal or of carbon.

Such a couple, for example, that is incapable of effecting the electrolysis of water,† or of a saline solution, although the heat given off by the couple is greater than the heat observed in the electrolyte, if its positive electrode (that is, the electrode of the voltaic couple) is of platinum, copper, or silver, becomes apt to produce this decomposition if its positive electrode is of carbon. The following is an

* Thermochemical energy is that which can be observed and measured by means of a thermometer, it is the energy produced in most batteries by the action of zinc on dilute sulphuric acid. = *Free energy*, or electromotive force, is the energy capable of causing electrolytic decomposition, without the power, however, of furnishing the energy necessary for the liberation of ions.

† The apparatus used for the electrolysis of water, or the voltammeter, consisted of a glass vessel filled with acidulated water and into which two electrodes of platinum wire were plunged.

example:—A mixed chromic and sulphuric acid couple* should give, according to Favre, 117.3 calories (2.5 volts), but only 62.5 calories (1.35 volts) would be transmitted to the circuit. (See "Traité des Piles Electriques," by D. Tommasi, p. 6).

Thus it results that a single chromic acid couple should not decompose water acidulated with sulphuric acid. As a matter of fact, if the positive pole of this element is of platinum-foil the water in the voltmeter is not decomposed, but if the positive pole is of carbon or of platinum-sponge, the electrolysis of the water takes place.

The chemical reaction produced in the interior of the chromic acid couple being always the same, no matter what the nature of the positive electrode is, I have endeavoured to determine approximately by means of electrolysis what voltaic energy (electromotive force) is transmissible to the circuit by this couple when its positive electrode is of platinum, carbon, or platinum-sponge. The following are the results I obtained.

a. The chromic acid couple, such as I have already described, that is to say, with a platinum positive electrode, only produces a voltaic energy transmissible to the circuit of 1.4 volts corresponding to 65.5 calories.

b. By substituting carbon or platinum-sponge for the platinum-foil in this couple we can obtain about 85 calories (1.8 volts) transmissible to the circuit, or 20 calories (0.43 volt) more than the preceding couple.

What I have just said on the subject of the electrolysis of water applies equally well to the decomposition of saline solutions by the electric current.

In fact, I have found that two zinc-platinum and dilute sulphuric acid couples, connected in series, will not decompose a solution of sulphate of potassium.

Now, by using two zinc-carbon and dilute sulphuric acid couples, it is easy to decompose a solution of sulphate of potassium with the evolution of gas at both poles, and the passage of the acid to the positive pole and the base to the negative pole.†

The two experiments I have quoted prove in an unmistakable manner that the transformation of thermochemical energy into voltaic energy (electromotive force) is more complete with a positive electrode of carbon than with one of platinum-foil.

From what I have just described it follows that in all battery cells the thermochemical energy engendered by the soluble electrode (the zinc, for example) should be transformed into voltaic energy by the unattainable body (carbon or platinum) which forms the positive electrode.

This transformation of thermochemical energy into voltaic energy by the positive electrode would be total or partial according to the nature and the physical state of this electrode.

It might also very well be that the carbon plays the rôle of a transformer similar to the induction coil, and like the latter is capable of converting a quantity current into one of intensity.

If that be the case, the increase of the electromotive force, due to the substitution of carbon for platinum in certain voltaic couples, should be obtained at the expense of their respective capacities. In other terms, if the constants of a voltaic couple are, for example, 2 ampères and 1 volt, that is 2 watts, and if by the fact of substituting carbon for the platinum the electromotive force is increased to 1.5 volts, the capacity should be decreased to 1.33 ampères, so that 1.5 volts $\times$ 1.33 ampères = 2 watts.

We notice a still more strange occurrence with the magnesium-platinum and dilute sulphuric acid couple.

* This couple consists of an outer glass vessel containing an amalgamated zinc plunged into dilute sulphuric acid, and a porous pot containing 25 grms. of chromic acid, 50 c.c. of water, and 10 c.c. of sulphuric acid.

† The electromotive force necessary to decompose dissolved sulphate of potassium was found to be about 103 calories. As a matter of fact, there is no electrolysis under the influence of voltaic systems equivalent to 76 calories (1.63 volts), or even 98 calories (2 volts). On the other hand, there is electrolysis with the evolution of gas at the two poles with systems equivalent to 115.8 calories (2.5 volts) and even 103 calories (2.24 volts).

This couple consists of a magnesium wire and a platinum wire plunged together into dilute sulphuric acid. According to known thermic data, this couple ought to decompose water, since the heat given off by the action of magnesium on dilute sulphuric acid is greater than the heat absorbed by the decomposition of water. Actually 112.4 calories, the heat given off by the action of magnesium on sulphuric acid > 69 calories, the heat of the decomposition of water; still, as I have observed, the decomposition does not take place.*

The same is the case if we substitute copper or silver for the platinum in the magnesium cell. But if we use a cylinder of graphite or retort carbon for the positive pole in this element, the electrolysis of the water takes place.

According to Gore, the electromotive force of the magnesium-platinum and dilute sulphuric acid couple is 1.92 volts, corresponding to 85.3 calories, and consequently well over the heat of the decomposition of water (69 calories), and still, as we have seen, water is not decomposed.

Now, it has been always admitted that there is an equivalence between the voltaic energy transmissible to the circuit and the electromotive force of a cell; in other words, if the electromotive force of a couple is equal to 1 volt, for example, this couple will be able to bring about the decomposition of some definite compound of which the heat of decomposition is lower than 46 calories, corresponding to 1 volt. How is it, then, that in the magnesium couple we have an exception?

I will return before long to this important question, the solution of which will give not only a more satisfactory explanation of physico-chemical phenomena which take place in voltaic couples, but will show further the true rôle played by the nature of the positive electrode in the transformation of the thermochemical energy engendered by the attackable metal into voltaic energy or electromotive force transmissible to the circuit, and alone capable of bringing about a chemical decomposition.—*Moniteur Scientifique*, Series 4, vol. xviii., June, 1904.

PEROXYLAMINESULPHONIC ACID.

By EDWARD DIVERS, M.D., D.Sc., F.R.S.,
Emeritus Professor of Chemistry, Imperial University of Tokyo.

ALTHOUGH unrecorded in works on chemistry or chemical technology, it has long been known to inspectors and workers of the lead-chamber process for manufacturing sulphuric acid, that when, through improper working of the chambers, sulphur dioxide is allowed to pass into the Gay-Lussac tower, it produces with the nitrososulphuric acid, also present in the tower, what is called "purple acid," together with an effervescence due to the escape of nitric oxide (Carpenter and Linder, *J. Soc. Chem. Ind.*, 1902, xxi., 1492). Sabatier has shown (*Comptes Rendus*, 1896, cxviii., 147, 1479, and 1537; cxviii., 255) how to give an intensely bluish-violet colour, evidently the same as that of "purple acid," to the monohydrate of sulphuric acid holding nitrososulphuric acid in solution, either by passing sulphur dioxide into it, or by mixing it with sulphuric acid of similar strength containing dissolved

* True electrolysis must not be confounded with *electro pseudolysis*; that is to say, the separation effected by the current of the only products resulting from the dissociation of the electrolyte. Thus, to give only one example, with a dilute solution of chloride of ammonium with the help of a current of which the electromotive force is lower than that necessary for the decomposition of the salt, we can observe a distinct transportation of ammonia to the negative pole and of hydrochloric acid to the positive pole. But in this case we are not dealing with a true electrolysis but with an *electro-pseudolysis*, since the current has merely separated the only products of the dissociation of the dissolved chloride of ammonium. What I have just said of chloride of ammonium applies equally well to the decomposition of most salts, such as sulphate of potassium, acetate of sodium, the cyanides, formates, &c., for example. It is the same with the decomposition of water effected with a current of which the electromotive force is much lower than 1.5 volts (0.01 volt, for example).

sulphur dioxide. Such a sulphuric acid solution of sulphur dioxide may also be treated for some time with a current of nitric oxide and air; or, excluding air, the nitric oxide alone will produce the colour, when a very small quantity of either copper sulphate or ferric or ferrous sulphate has been previously dissolved in the acid. Lastly, certain metals and other substances serve to produce this colour, or a modification of it, by acting on nitrososulphuric acid in monohydrated sulphuric acid, among them being finely divided copper, silver, or mercury. Sabatier has not isolated the substance which gives this violet colour to sulphuric acid treated by the foregoing processes, but has suggested that it may be the unknown acid of Fremy's *sulphazilate*, which he re-names *nitrosodisulphonic acid*.

Now, in a preceding paper on peroxylaminesulphonates, Haga has adduced reasons for doubting the correctness of Sabatier's suggestion that the bluish-violet acid is sulphazilic acid, that is, peroxylaminesulphonic acid. There is also one consideration which, although not mentioned by Haga, may nevertheless have affected his judgment. This is the fact that a substance which, according to Haga's most conclusive evidence, must be a peroxide, should be produced in the ways prescribed by Sabatier. But this difficulty and those raised by Haga all seem to disappear when the changes which give rise to the acid and the very different conditions for the production of the salt and of the acid are all more closely examined, and leave nothing in the way of accepting the view that this acid is peroxylaminesulphonic acid.

The fact that the violet acid is dissolved in sulphuric acid, whereas the violet salt is in aqueous solution, has to be taken into account when the differences in the behaviour of the two are under consideration. It will then be seen that these differences are really not greater than those between a sulphuric acid solution of nitrous acid (as nitrososulphuric acid) and an aqueous solution of potassium nitrite. The latter when acidified and the former when diluted both quickly lose most of the nitrous acid, there being no stable existence of this acid in the intermediate conditions. Potassium nitrite is unaffected by hydrogen peroxide or potassium permanganate, being, in fact, producible from nitric oxide by alkaline hydrogen peroxide (Carpenter and Linder, *loc. cit.*), and from hyponitrite by permanganate (Thum, *Monatsh.*, 1893, xiv., 294), whereas nitrous acid is converted by these reagents into nitric acid. Lead peroxide may therefore very well be active towards a sulphuric acid solution of peroxylaminesulphonic acid, although it does not interact with an aqueous solution of its salts. Again, that sulphur dioxide should not interact with peroxylaminesulphonic acid in presence of much sulphuric acid, and yet be very active towards a salt of the acid in water, may well be an instance of what indeed happens in case of mercuric oxy-salts, on which, in presence of much sulphuric acid, sulphur dioxide is no longer active (*Journ. Coll. Sci. Tokyo*, i., 106), or in that of ferric salts, which are very much more easily reduced by sulphur dioxide in the absence of sulphuric acid than in the presence of excess of it. Similarly, it may further be properly maintained that it does not follow that hydroxylaminetrisulphonic acid should be produced from peroxylaminesulphonic acid in sulphuric acid solution because its salt is produced in a neutral or an alkaline aqueous solution of a peroxylaminesulphonate. This contention being admitted, the non-formation of this acid, observed by Haga, is not significant.

Since the well-known compound, nitrososulphuric acid, is not a sulphonic derivative, as Sabatier takes it to be, but the mixed anhydride of nitrous and sulphuric acids, the nature of its conversion into the violet acid is easy to understand. Regarding the mixed anhydride as being simply nitrous anhydride (the sulphuric acid being undecomposed), the production from it of nitric oxide and peroxylaminesulphonic acid is seen to be only its usual decomposition into nitric oxide and nitric peroxide, except that the latter product is now sulphonated—

When metallic copper is used in place of sulphur dioxide, the generation of the necessary sulphur dioxide by the action of the metal on the pyrosulphuric acid of the nitrososulphuric acid only introduces an interesting complication. Pyrosulphuric acid at once interacts with copper in the cold (*J. Chem. Soc.*, 1885, xlvii., 638).

There remains to be considered the production of the "purple acid" along with nitrososulphuric acid from nitric oxide and sulphuric acid in the presence of cupric or ferric sulphate as a catalytic agent. The sulphuric acid being represented as existing in its pyro-state (the form in which it acts in presence of an oxide of nitrogen), the change is expressed by the equation—

As to the peroxidising action of sulphuric acid here shown, it may be well to recall the action of the acid upon metallic tin in presence of hydrochloric acid (Heumann and Koechlin, *Ber.*, 1882, xv., 420):—

In this equation the stannic chloride and the sulphur dioxide together take the place of the peroxylaminesulphonic acid in the previous one, for $[\text{ON}(\text{SO}_3\text{H})_2]_2$ can evidently be expanded into $\text{N}_2\text{O}_4 + 4\text{SO}_2 + 2\text{OH}_2$.

It is difficult to conceive of any other rational interpretations of Sabatier's remarkable results than those given above, and these are all consistent with the assumption that the purple acid is not merely isomeric, but actually identical with peroxylaminesulphonic acid, and is therefore a peroxide and an exclusively tervalent nitrogen compound.—*Journal College of Science, Imperial University, Tokyo*, xix., Art. 16.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING JUNE 30TH, 1904.

By SIR WILLIAM CROOKES, F.R.S.,

and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,

Water Examiner, Metropolitan Water Act, 1871.

London, July 11th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board and the Directors of the New River Company, the results of our analyses of the 203 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board and the New River Company taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from June 1st to June 30th inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 203 samples examined by us during the month, all were clear, bright, and well filtered.

The rainfall at Oxford during the month of June has been considerably below the average, only 1.04 inch of rain having been recorded. The mean rainfall for June is 2.10 inches; thus we have a deficit of 1.06 inch, which, if deducted from the previous excess of 2.43 inches, leaves a total excess for the first six months of the year of 1.37 inches, or 12.6 per cent above the thirty-five years average.

Our bacteriological examinations of 384 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 380 others from special wells, standpipes, &c., making 764 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 26 samples) ..	112
New River, filtered (mean of 76 samples) ..	6
Thames, unfiltered (mean of 26 samples) ..	883
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 205 samples) ..	20
Ditto ditto highest	310
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	182
River Lea, from the East London Water Com- pany's clear-water wells (mean of 25 samples) ..	12

Of the 306 daily samples taken from the general filter wells of the Metropolitan Water Board and the New River Company, eighteen samples, or 6.0 per cent, were sterile. Nine samples, or 3.0 per cent, contained more than 100 microbes, and of these, two samples contained more than 150 microbes per c.c. The nine excess samples contained an average of 152 microbes per c.c. In May five excess samples contained an average of 143 microbes per c.c.

The results of the analyses show that the water distributed to London, under the direction of the Metropolitan Water Board and the New River Company, during the month of June has been efficiently stored and filtered; and that the high degree of purity recorded throughout the two previous months has been well maintained.

We are, Sir,
Your obedient Servants,
WILLIAM CROOKES.
JAMES DEWAR.

NOTICES OF BOOKS

The Vegetable Alkaloids. By DR. AMÉ PICTET. Rendered into English from the Second French Edition by H. C. BIDDLE, Ph.D. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

This translation of Prof. Pictet's valuable treatise on the vegetable alkaloids will probably constitute the most complete text-book of its kind dealing with this subject in the language. The many advances which have been made during the last seven years have necessitated the re-writing of many chapters, such as those, for instance, dealing with the alkaloids prepared from the tobacco plant, but the general method and plan of Prof. Pictet's work are preserved as closely as possible. The first part of the book deals with the artificial bases closely related to the natural alkaloids, pyridine and its homologues and derivatives, and the preparation and properties of them are described as fully as is necessary for the purpose. In the second part the natural alkaloids are classified, and their methods of synthesis discussed at length.

Die Riechstoffe. ("Aromatic Substances"). By DR. GEORG COHN. Braunschweig: Friedrich Vieweg und Sohn. 1904.

This treatise on the chemistry of aromatic substances forms a part of Bolley and Engler's "Handbuch der Chemischen Technologie," and deals very exhaustively with a subject which is full of interest both from a scientific and technological point of view. The chief desiderata in a work of this kind are accuracy and systematic arrangement, and in both of these particulars, as far as they can be tested, there seems to be no fault to find with it. The plants which yield ethereal oils are tabulated in families, and the physical constants and chemical constituents of

the oils are also conveniently given in tabular form. Great attention is paid to the isolation and synthesis of the aromatic substances, which are described in detail under the headings of the various classes of chemical compounds to which they severally belong. The quantitative determination of the oils is adequately treated, and the chapters on their physical and physiological behaviour, where the author finds more scope, are very interesting reading.

CORRESPONDENCE.

WILLIAMSON'S THEORY OF ETHERIFICATION.

To the Editor of the Chemical News.

SIR,—The following extract from Brande's "Manual of Chemistry," 1848, vol. ii., p. 1677, speaks for itself (it seems to me to contain Williamson's theory of etherification in a nutshell):—"The continuous supply of alcohol furnishes materials for the constant formation of sulphovinic acid, and the sulphovinic acid (containing 2 atoms of anhydrous sulphuric acid and 1 of alcohol) is no sooner formed than it is resolved into sulphuric acid, ether, and water . . ." The clause in the quotation within parentheses apparently simply means that Brande regarded sulphovinic acid as an acid sulphate. It looks from this that Williamson simply elaborated Brande's idea.—I am, &c.,

JOHN GEDDES MCINTOSH.

Analytical Laboratory,
9, Parsonage Street, Cubitt Town, E.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 25, June 20, 1904.

A New Carbide of Molybdenum, MoC.—H. Moissan and K. Hoffmann.—When a mixture of molybdenum, carbon, and excess of aluminium is heated in the electric furnace, a molybdenum carbide of formula MoC is formed. This is a hard substance, unattacked except with great difficulty by all acids but nitric. It is not decomposed by cold water or by water vapour at 600°. This carbide is analogous to Williams's tungsten carbide; this fact not being surprising, as molybdenum and tungsten are similar metals. It is also apparent that this compound enters into molybdenum steels under the form of double carbide. During its preparation it is observed that, at the boiling temperature of aluminium, a compound of molybdenum is formed which contains twice as much carbon as if its carburation took place at the higher temperature of the electric furnace.

Investigations on the Cementation of Carbon Steels and other Varieties of Steels.—Léon Guillet.—The author's researches show—(1) That the nitrogen in the cementation vessel has an action in certain cements by the formation of a cyanide; also cements containing potassium salts have a non-constant penetration velocity. (2) Elements merely dissolved in iron retard cementation, whilst those which are found to be in the state of a double carbide assist cementation. (3) Iron dissolves carbon considerably, even at moderate temperatures.

Formation of Isomorphous Mixtures of Lime and Lithia.—P. Lebeau.—By the fusion of a mixture of calcium carbonate and lithium carbonate in a current of carbon dioxide, a limpid product results, solidifying to a white crystalline mass. On digesting with a small quantity of

Preparation of Alkyl Sulphinic Acids.—Arthur Rosenheim and Ludwig Singer.—If dry sulphur dioxide is led into an ethereal solution of an alkyl magnesium haloid compound, the gas is absorbed with such evolution of heat

that external cooling of the vessel is necessary. After saturation a white crystalline mass is obtained, which may be re-crystallised from water, and is the pure magnesium salt of the sulphinic acid. This method is analogous to Grignard's for the preparation of monocarboxylic acids, by passing carbon dioxide into alkyl magnesium haloids.

Use of Sodium Peroxide for the Qualitative Analysis of Organic Substances.—Hans H. Pringsheim.

—The author describes a method for the qualitative determination of chlorine, bromine, iodine, phosphorus, arsenic, and sulphur by means of sodium peroxide. For this method he claims the following amongst other advantages:—It is absolutely trustworthy, the same product of ignition can be used for all six elements, the halogens if present together can be rapidly detected, and the method can be applied to volatile substances. Only a very small quantity of the substance is required, and the ignition is accomplished within one minute. The method is as follows:—To a weighed quantity of sodium peroxide 25 times its weight of a substance which contains much carbon and oxygen, and is not hygroscopic, is added, e.g., cinnamic acid or naphthalene. This mixture may be kept in a well-closed vessel. Enough of this oxidation mixture to cover the point of a knife is added to some grains of the solid or a few drops of the liquid in an iron tube, which is heated in a Bunsen burner till the beginning of the reaction is indicated by a decided odour. The tube is then cooled, the product of the reaction is dissolved in water, and the solution divided into two parts. The halogens and phosphorus may be detected in the usual way in the one after acidulation with nitric acid, and the sulphur and arsenic in the other after addition of hydrochloric acid. If bromine and iodine are present as well as chlorine, these elements can be conveniently separated in the solution made feebly acid with nitric acid on addition of chlorine water, and shaking with carbon disulphide.

Researches in the Camphor Group.—J. W. Brühl.

—The author describes the synthesis and properties of some halogen derivatives of camphor, especially di-iodocamphor and iodo-formyl-camphor. Claisen has shown that bromine with an alkaline solution of oxy-methylene camphor gives *o*-bromocamphor, while in an indifferent medium, such as perchloromethane, bromo-formyl-camphor is formed. The author now finds that iodine with an alkaline solution of oxy-methylene camphor always gives *o*-*o*-di-iodocamphor, and in absence of excess of alkali iodo-formyl-camphor may be isolated. This difference in the behaviour of iodine and bromine towards an alkaline solution of oxy-methylene camphor is all the more remarkable because the dibromo-compound is very stable, while the di-iodo body is far less so. Also of the two compounds which may be isolated in neutral solution the bromo-formyl-camphor is far more stable than the iodo-formyl camphor. It seems, however, that this latter, though actually the less stable, is more stable towards alkalis.

Determination of Palladium and its Separation from other Metals by means of Hydrazine.—P. Jannasch and W. Bettges.

—A weighed quantity of the previously purified metal is dissolved in about 5 c.c. of aqua regia, warmed for a short time on the water-bath, covered, and allowed to stand for some minutes. It is then heated more strongly, and finally evaporated to dryness. The residue is taken up with a little water to which about 20 drops of dilute hydrochloric acid have been added. It readily dissolves on warming on the water-bath, and the solution is then made up to about 120 c.c. To determine the metal, the faintly acid solution is heated almost to boiling, and the palladium is precipitated with 1 gm. of hydrazine sulphate (dissolved in about 20 c.c. of water). The metal begins to separate out at once with energetic evolution of nitrogen, and after warming for twenty minutes the reaction is complete. The fine black precipitate first obtained collects to form a spongy mass, which is washed and dried at 120° to 130° in a weighed asbestos ignition tube, and then reduced in a current of hydrogen. The

palladium thus obtained is a dull silver grey mass, and the author suggests that the black palladium which, according to the text-books, is separated from palladium solutions by means of zinc, iron, hydrogen, &c., consists really of a mixture of oxides. The precipitation of palladium in acid solution by means of hydrazine may be used to separate the metal from potassium, sodium, magnesium, zinc, and iron.

Separation of Mercury from Molybdenum and Tungsten by means of Hydrazine.—P. Jannasch and W. Bettges.

—*Separation of Mercury and Molybdenum.*—0.2 to 0.3 gm. of finely powdered molybdic acid is dissolved in water to which excess of ammonia containing a few drops of soda solution has been added. The solution is warmed on the water-bath to drive off excess of ammonia, and 2 to 3 grms. of tartaric or citric acid are added. Then mercury chloride is added, any turbidity being dissolved by means of a few drops of hydrochloric acid, and the solution is diluted to 100 c.c. It is then warmed to about 80° with addition of a warm solution of 2 grms. of hydrazine sulphate in 30 to 45 c.c. of concentrated ammonia. After heating for a quarter of an hour with frequent stirring it is allowed to stand for three or four hours, and then filtered. The precipitate of mercury is separated off, converted into sulphide, and determined as such, while the molybdenum in the filtrate is determined as tri-sulphide by the addition of ammonium sulphide, according to a method previously described by Jannasch. *Separation of Mercury and Tungsten.*—No tartaric or citric acid is added, but otherwise the method is essentially the same as the above. Ten to 15 c.c. of fuming nitric acid are added to the filtrate, which is then evaporated to 50 c.c., when tungstic acid separates out as a fine yellow precipitate, which may be dried and weighed. *Direct Determination of Tungsten in Tungstates.*—0.5 gm. of sodium tungstate is dissolved in 50 c.c. of water, and to the boiling solution is added a solution of 2 grms. of hydrazine hydrochloride in 10 c.c. of water and 20 c.c. of concentrated hydrochloric acid. A precipitate forms, and characteristic colour changes ensue. The precipitate, which becomes finally green coloured, is washed with very dilute nitric acid, dried, and ignited, and weighed as WO₃.

2-Phenyl-hypoxanthine and 2-Phenyl-adenine.—Wilhelm Traube and Ludwig Hermann.—2.3 grms. of sodium are dissolved in absolute alcohol, and 11.5 grms. of cyanacetic ester and 12 grms. of free benzamidine are added. After standing for twelve hours the liquid is quickly evaporated on the water-bath, the residue dissolved in water (a few drops of caustic soda being added if necessary), and acetic acid added till the solution is decidedly acid. 2-Phenyl-4-amino-6-oxypyrimidine collects in small colourless or yellow crystals, readily re-crystallised from hot water or alcohol. This is dissolved in dilute alkali and sodium nitrite, and dilute sulphuric acid gradually dropped in, the liquid being kept in constant motion. The iso-nitroso body is thus formed, and may be reduced by means of ammonium sulphide solution to 2-phenyl-4,5-di-amino-6-oxypyrimidine, which gives 2-phenyl-hypoxanthine with excess of concentrated formic acid. Freshly distilled phosphorus oxy-chloride converts the 2-phenyl-hypoxanthine into 2-phenyl-6-chlor-purine, which yields 2-phenyl-adenine when heated with saturated solution of ammonia under pressure for some hours.

Conversion of Sorbic Acid into Amino Acids.—

Emil Fischer and Fritz Schlotterbeck.—It is difficult to prepare diamino acids, especially those in which the amino groups are in the positions 1-3 or 1-4. The authors found that by heating sorbic acid with a large excess of concentrated aqueous ammonia for some time to 150° they obtained a body which possessed the properties of diamino acids and had the composition C₆H₁₄N₂O₂. It is thus a diamino caproic acid, but differs from the α - δ compound already known (inactive lysine). If the syrupy liquid is heated longer to 150° or distilled under greatly diminished pressure, it is partially converted into a crystalline product,

$\text{C}_6\text{H}_9\text{NO}$, which is the anhydride of an unsaturated amino-acid, $\text{C}_6\text{H}_{11}\text{NO}_2$, a derivative of normal caproic acid which we called amino-hexene acid. In all probability this compound is an unsaturated derivative of a methylated piperidone or pyrrolidone. Hence, in the original diamino caproic acid one amino group was in the γ or δ position to the carboxyl. Nothing definite can be said about the second amino group. The anhydride, when heated for some hours with excess of baryta water, forms an amino acid which, from its similarity to pyrrolidine carboxylic acid, may perhaps be methyl pyrrolidine carboxylic acid, which would easily be formed from δ -amino hexene acid.

MISCELLANEOUS.

Institute of Chemistry of Great Britain and Ireland.

—*Examination in Biological Chemistry. October, 1904.*—An Examination in Biological Chemistry will be held at the Laboratories of the Institute, commencing Tuesday, October 25th, 1904. The Examination will be open to candidates whose applications for admission to the Final Examination have been accepted by the Council, to candidates who have passed the Intermediate Examination, and also to Fellows and Associates of the Institute who desire to obtain a certificate of competency in this branch of work. The Examination will extend over four days, and may be theoretical, practical, written, and oral. The syllabus will include Biological Chemistry, with special reference to the Chemistry and Bacteriology of Foods, Water, Sewage, and Effluents, and to the practical applications of Biological Chemistry to Industries. Candidates intending to enter for the Examination are recommended to study the following subjects:—1. Elementary Biology. 2. The Morphology, Physiology, and Life History of Bacteria, Yeasts, and Moulds, in their relation to Food, Water Supply, the Treatment of Sewage, Agriculture, and the Fermentation Industries. (A special study of pathogenic organisms is not demanded, but the candidate should acquire a knowledge of such as are of importance in relation to Food and to Water Supply). Practical work should include:—(a) General bacteriological methods and preparation of pure cultures; (b) Microscopy: the staining and mounting of preparations, and the recognition of species; (c) Fermentation changes caused by micro-organisms. 3. Enzymes and their actions. 4. The methods employed in the examination and estimation of the carbohydrates. 5. The proteids and their decomposition products.

The Boiling and Evaporation of Metals in a Cathodic Vacuum.—F. Krafft.—The author has used distilling apparatus for his experiments made of fused blown quartz. Such apparatus supports a temperature of 1400° , and resists sudden changes of temperature perfectly well. He heats these tubes in an electric furnace, and measures the temperature by means of a thermoelectric junction. He has observed that in a cathodic vacuum fused metals emit vapours at relatively low temperatures, and he has succeeded in distilling a large number. Zinc gives off vapours at as low a temperature as 300° , and distils at about 640° ; cadmium distils at 450° , selenium at 380° , tellurium at about 550° , lead at 1180° ; tin does not vapourise at 1100° ; antimony distils at 775 – 780° , bismuth at about 1045 – 1050° ; silver sublimates rapidly at 1200° without distilling, copper sublimates at 1315° , its boiling-point is probably about 1500 – 1600° ; gold sublimates slowly at 1375° . Finally, the author has observed that the boiling-point rises when the height of the column of vapour of the metal formed above the surface of the boiling liquid increases. He considers that boiling in vacuum consists first of the formation of vapours which thus produce an atmosphere, and that boiling takes place when the vapour tension of the liquid is equal to the pressure which exists on the surface. Thus we understand why the boiling-point rises when the column of vapour increases in height.—*Berichte*, vol. xxxvi., p. 1690.

The Sanitary Institute.—The Twenty-second Congress of this Institute will be held at Glasgow from July 25th to 30th, under the Presidency of the Right Honourable Lord Blythswood, LL.D., Lord-Lieutenant of Renfrewshire. A lecture will be given to the Congress on July 27th by Sir Richard Douglas Powell, Bart., M.D., &c., on "Prevention of Consumption," and a number of Popular Lectures will be given during the week in the Exhibition which will be held in connection with the Congress. There will be three Sections as follows:—Section I. Sanitary Science and Preventive Medicine—President, Prof. J. Glaister, on July 26th and 27th. Section II. Engineering and Architecture—President, Prof. Henry Robinson, M.Inst.C.E., on July 27th and 28th. Section III. Physics, Chemistry, and Biology—President, Prof. Frank Clowes, D.Sc., &c., on July 28th and 29th. Conferences on various subjects connected with Sanitary Science will also be held, and numerous papers will be read and discussed. On Saturday, July 30th, excursions will be made to various places of interest in the neighbourhood; also during the week there will be several entertainments, such as Garden Parties, Concerts, Receptions, and Afternoon and Evening Cruises. Further information can be obtained from the local Secretary, Mr. J. Lindsay, City Chambers, Glasgow, or E. White Wallis, Esq., the Secretary of the Institute, Margaret Street, London.

Solubility of the Red and Yellow Oxides of Mercury and their Dissociation.—Karl Schick.—The question of the identity or the isomerism of the red oxide and the yellow oxide of mercury has been already the subject of several papers. The author agrees with the opinion expressed by Ostwald, according to which the two bodies are identical chemically, but differ in the size of their particles; relying on this opinion, he has measured their solubility in distilled water at a temperature of 25° . By operating with carefully purified water, and of which the purity was controlled by measurements of conductivity, and taking care to prolong the experiment sufficiently to make certain of reaching a state of equilibrium, he found the following results:—The solubility of the yellow oxide was 0.0518 grm. per litre, or 1 part of oxide in 19,300 parts of water; the solubility of the red oxide was 0.0513 grm. per litre, or 1 part in 19,500 parts of water; thus the two solubilities were practically equal. Ostwald's opinion is again confirmed by the fact that during the measurements made on the red oxide, the author has observed the transformation of this body into the yellow oxide. Measurements made in boiling water, for a few hours only, have given the following results:—For the yellow oxide, 0.41 grm. per litre, or 1 part in 2400 parts of water; for the red oxide, 0.38 grm. per litre, or 1 part in 2600 parts of water. It cannot be doubted but that more prolonged experiments would give still closer solubilities. The presence of the ions OH , increases the solubility of the oxide of mercury in water, proportionally to their quantity. This may be explained by the fact that these dissolved metallic oxides (alkalis or alkaline earths), when in contact with solutions of mercuric oxide, give salts in which the mercury forms a complex anion with the oxygen. Solutions of mercuric oxide are the seat of a very slight dissociation, as is shown by the measurements of saponification and conductivity; their prolonged contact does not perceptibly saponify acetate of ethyl at 25° , but the addition of a neutral salt causes a rapid saponification; their conductivity is very slightly better than that of the water employed to make them. The addition of haloid salts to these solutions increases their proportion of ions of OH , on account of the formation of sublimate or of complex mercurio-haloid compounds. The reaction is relatively slow, but its speed can be increased by the addition of a large excess of an alkaline haloid, so that it becomes practically instantaneous and complete. Finally, it has been observed that the colour of the yellow oxide depends on the temperature, and that when this rises the colour passes progressively from yellow to red.—*Zeit. Physik. Chem.*, vol. xlii., p. 155.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.

Founded 1877. Incorporated by Royal Charter 1885.

An EXAMINATION IN BIOLOGICAL CHEMISTRY, with special reference to the Chemistry and Bacteriology of Foods, Water, Sewage, and Effluents, and to the practical applications of Biological Chemistry to Industries, will be held at the Laboratories of the Institute, commencing on **TUESDAY, the 25th day of OCTOBER, 1904**, and will extend over four days.

The Examination will be open to Candidates whose applications for admission to the Final Examination have been accepted by the Council, to Candidates who have passed the Intermediate Examination, and also to Fellows and Associates of the Institute who desire to obtain a certificate of competency in this branch of work.

The List of Candidates will be closed on **TUESDAY, the 26th day of SEPTEMBER, 1904**. For further particulars apply to the REGISTRAR, 30, Bloomsbury Square, London, W.C.

"The Book of Regulations" for Admission to the Institute can be obtained from Messrs. Blundell, Taylor, & Co., 173, Upper Thames Street, London, E.C., price One Shilling.

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTION.

Directors:

The Right Hon. LORD RAYLEIGH, O.M., M.A., D.C.L., LL.D., Sc.D., F.R.S.

SIR JAMES DEWAR, M.A., LL.D., D.Sc., F.R.S.

Superintendent of the Laboratory:

DR. ALEXANDER SCOTT, M.A., D.Sc., F.R.S.

This Laboratory was founded by DR. LUDWIG MUND, F.R.S., as a Memorial of Davy and Faraday, for the purpose of promoting, by original research, the development and extension of Chemical and Physical Science.

MICHAELMAS TERM.—Monday, October 3, to Saturday, December 17.

LENT TERM.—Monday, January 9, to Saturday, April 15.

EASTER TERM.—Monday, May 8, to Saturday, July 22.

Full information and forms of application can be had from the Assistant Secretary, Royal Institution, Albemarle Street, W.

To prevent delay Candidates ought to send in their applications for admission during the course of the Term preceding that in which they wish to enter.

BIRKBECK COLLEGE

(BIRKBECK INSTITUTION),

Breams Buildings, Chancery Lane, E.C.

DAY and EVENING SCIENCE CLASSES—

CHEMISTRY	J. E. MACKENZIE, Ph.D., D.Sc.
PHYSICS	A. GRIFFITHS, D.Sc.
MATHEMATICS ..	E. H. SMART, M.A.
BOTANY	A. B. RENDLE, M.A., D.Sc.
ZOOLOGY	H. W. UNTHANK, B.A., B.Sc.
GEOLOGY & MINERALOGY	G. F. HARRIS, F.G.S.
METALLURGY, MINING, and ASSAYING ..	G. PATCHIN, A.R.S.M.

Classes in FRENCH, GERMAN, SPANISH, RUSSIAN, ITALIAN, DUTCH.

Courses for University of London, Conjoint Board, Dental, and Pharmaceutical Examinations.

PRACTICAL WORK in highly equipped Laboratories.

ST. PAUL'S SCHOOL, West Kensington.—

An EXAMINATION will be held at the above School on Tuesday, September 6th, 1904, and on the following days, for filling up about Twenty Vacancies on the Foundation.—Full particulars of the Examination can be obtained on application to the Bursar.

ZINC

Suitable for the MARSH-BERZELIUS Test for ARSENIC, As described in the "Report of the Inland Revenue Departmental Committee on Arsenic-Testing."

LOCKE, BLACKETT, & CO., Ltd.,

DENTISTRY.

Leading to Degrees and Diplomas.

The Session 1904-5 commences October 3rd, 1904.

ALL COURSES AND DEGREES ARE OPEN TO BOTH MEN AND WOMEN STUDENTS.

In the Medical School there is a separate Dissecting Room for Women, with a qualified Woman Demonstrator.

Graduates of other Universities may, after two years' study or research, take a Master's degree.

SYLLABUSES with all information will be sent on application to the Secretary.

THE DURHAM COLLEGE OF SCIENCE, NEWCASTLE-UPON-TYNE.

Complete Courses of Instruction are provided

for Students of both sexes proceeding to the University Degrees in Science, or in Letters, and for the University Diploma in Theory and Practice of Teaching. Special facilities are offered for the study of Agriculture, Applied Chemistry, Mining, and all branches of Engineering and Naval Architecture.

Matriculation and Exhibition Examinations begin September 26th.

Lectures begin October 4th, 1904.

Prospectuses on application to the SECRETARY.

INSTRUCTION IN PURE CULTIVATION OF YEAST. According to Hansen's Methods.

Courses for Beginners, as well as for Advanced Students, in Physiology and Technology of Fermentations. Biological Analysis of Yeast. The Laboratory possesses a numerous collection of yeast brewers', distillers', wine, disease yeasts, moulds, and bacteria.

Manuals: E. Chr. Hansen, "Practical Studies in Fermentation," London (Spon), 1896. Alfred Jørgensen, "Micro-Organisms and Fermentation," London and New York (Macmillan and Co.), 1900.

The Laboratory supplies for direct use: Cultures of yeast for breweries, distilleries, wine manufactories, &c.

Further particulars on application to the Director—

ALFRED JØRGENSEN, The Laboratory, Copenhagen, V.

ABSOLUTE ALCOHOL, FREE FROM DUTY, FOR SCIENTIFIC AND RESEARCH WORK IN LABORATORIES.

To be obtained from

HUGO LORENZ,
7-8, Idol Lane, Great Tower St., London, E.C.,

Licensed Trader in Alcohol and Spirits of Wine.

Stock kept in suitable packages ready for immediate use.

THE ATOMIC WEIGHT OF TUNGSTEN.*

By EDGAR F. SMITH and FRANZ F. EXNER.

(Continued from p. 39).

TAYLOR's experience re-emphasised the absolute necessity of satisfying ourselves beyond every reasonable doubt that the material for the atomic weight determinations was pure; at least as pure as the means at hand would furnish. The admission of Schneider that his purest substance contained traces of impurity, insoluble in caustic potash, and Taylor's discovery that every sample of tungsten trioxide tested by him gave a residue, insoluble in sodium carbonate, made us very solicitous regarding the purity of all material which had been used in any previous investigations, for it will be found upon consulting the literature that almost every experimenter was content to proceed with ammonium paratungstate which was perfectly white in colour. Three to five re-crystallisations were held to be sufficient to attain that condition.

Our doubts became so overwhelming that it was decided to begin the work anew with the mineral wolframite, and to ascertain, once for all, what it contained in order that search might be made for all such constituents, and every effort put forth to ensure their perfect removal from the salts which might be experimented upon. Accordingly, in the summer of 1901 large quantities of wolframite, from Lawrence County, S.D., were decomposed, and the resulting tungstic acid converted into ammonium paratungstate. The mother-liquors from the salt were black in colour, and gave in due time the interesting compound—ammonium vanadico-phosphotungstate—described by us in the *Journ. Am. Chem. Soc.*, xiv., 573. Its discovery added, of course, vanadium and phosphorus to the list of possible contaminating substances: columbic oxide, silica, molybdic oxide, ferric oxide, manganese oxide, &c. Large amounts of ammonium paratungstate were taken for the purification of the tungsten trioxide by methods which may now be presented.

Method 1.—This first fraction was collected apart, dissolved in distilled water, and re-crystallised; the first crystallisation was again set aside and dissolved, this operation being repeated ten times. A portion of the sixth crystallisation was ignited in a platinum crucible, and the resulting oxide was digested on a water-bath with a 2 per cent solution of sodium carbonate free from iron. The oxide dissolved, but its solution was quite turbid. Upon standing, a white residue settled out, which after washing with water and decomposition with a few drops of hydrochloric acid, showed tungstic acid and iron. Portions of the tenth re-crystallisation behaved similarly. The mother-liquors, including that from the tenth crystallisation, assumed a dark brown colouration upon concentration, indicating thereby that not only iron, but that also the vanadico-phosphotungstate, already alluded to, continued with the ammonium tungstate. Vanadium too was found in a portion of the tenth crystallisation when it was heated in an atmosphere of hydrochloric acid gas. Hence it was concluded that this method was unsatisfactory, and it was abandoned. Chemists, who in the past were content to look upon ammonium paratungstate as being very pure when its colour was perfectly white (and from published statements most have been content with this criterion), which it is after the third or fourth crystallisation, cannot have had pure substance for their investigations, hence the fluctuation in their results is easily comprehended.

Method 2. This may be called the method of Borch. In it the mineral was fused with sodium carbonate, the fusion exhausted with water, and after filtration the liquid was precipitated with calcium chloride. The resulting calcium tungstate was filtered, washed, and decomposed with hydrochloric acid. The liberated tungstic acid was dissolved in ammonia water, and the ammonium salt crystallised out. The method was carried out with rigid adherence to the printed instructions, but it proved entirely unsatisfactory.

Method 3.—Solutions of ammonium paratungstate, decidedly brown in colour, were boiled with precipitated calcium carbonate. Ammonia and carbon dioxide were evolved, while calcium tungstate was precipitated. The solutions lost nothing in colour. After filtering out and washing the calcium tungstate it was boiled with hydrochloric acid. Tungstic acid of a rich yellow colour separated. It was washed and dissolved in ammonia water. There was a very slight bluish coloured residue. The ammonium paratungstate, which crystallised out, was perfectly white in colour, but a portion of it ignited, and the resulting oxide, digested with a dilute sodium carbonate solution, disclosed the usual white residue in which tungsten and iron were found.

The salt, purified in this way, was fully as free from impurities as a salt which had passed through six crystallisations from water. This fact led us to prepare pure calcium carbonate and hydrochloric acid before repeating the method with another portion of ammonium paratungstate.

Commercial calcium carbonate was boiled with a solution of pure ammonium chloride. Iron and other impurities remained with the excess of calcium carbonate. The filtrate from the latter was precipitated with pure ammonium carbonate. The resulting calcium carbonate was thoroughly washed, and then dried.

Ordinary hydrochloric acid was saturated with calcium chloride, and after the addition of phosphorus pentoxide was distilled with water. This gave pure acid. With these purified reagents ammonium paratungstate, which had passed through several crystallisations, was subjected to the treatment outlined in the beginning of this section. The purified salt, when tested, showed but traces of impurities, and it is very probable that these, after several repetitions, would disappear entirely. The actual trial was not made, because another course seemed to lead to the desired end in a much shorter period. Experience also showed that nitric acid was preferable.

Method 4.—In this procedure a boiling solution of ammonium paratungstate was decomposed with hydrochloric acid. The precipitated tungstic acid was again dissolved in ammonia, and the decomposition repeated. Repeating this process several times yielded tungstic acid which might be asserted to be quite pure, although when the mother-liquors from the several fractions of the ammonium salts were reduced to a small volume the dark colour appeared. A white residue, although slight, was also obtained from the ignited tungsten trioxide. Wyman (Thesis, University of Pennsylvania, 1902) found, after twenty-five decompositions with hydrochloric acid, evidences of similar contamination. This chemist tried seven different schemes in his endeavour to obtain pure tungstic acid, without the desired result. Accordingly, on resuming this part of our study in the summer of 1902 we determined to eliminate every possible source of contamination from the various reagents which we proposed using. Thus, 15 litres of hydrochloric acid were purified as already described. It was free from every impurity, which was proved by carefully repeated tests. Eighteen litres of nitric acid were distilled after the addition of pieces of pumice and some sodium hydrogen phosphate. The product left no ponderable residue when a definite volume of it was evaporated to dryness in a platinum vessel. The sodium carbonate was made pure by fusing it in a platinum vessel, and introducing into the molten mass a small quantity of pure, precipitated calcium carbonate which dissolved, the mass

* From *Proceedings of the American Philosophical Society*, vol. xliii., No. 176.

being held for five minutes in the liquid state. After cooling, the fusion was allowed to dissolve out in cold water. The calcium carbonate, iron, &c., were filtered off, and the solution evaporated to crystallisation. The sodium carbonate which separated was re-crystallised four times. Platinum vessels were used for the purpose. They are essential. Portions of the purified salt were examined for silica and iron, and their absence demonstrated. There was now every reason to believe that the reagents, including the water (for it had been re-distilled), were pure. They contained nothing which would contaminate the tungsten trioxide. Therefore if the latter left a residue upon digestion with a dilute sodium carbonate solution, that residue plainly came out from the tungstic oxide.

And now we must digress a little. Wyman experienced difficulty and annoyance in his efforts to dissolve tungstic acid in ammonia water. Others have had, doubtless, similar experiences. There invariably remains a bluish-white mass which no amount of ammonia or protracted boiling eliminates. More than a kilogram of this substance had accumulated from Wyman's work, and came into our possession. Its bluish-green tint suggested the presence in it of some reduction product, probably occasioned by the hydrochloric acid. We accordingly projected the mass into boiling concentrated nitric acid. A violent evolution of chlorine immediately followed, and continued until the material had acquired a rich yellow colour. Whence came the chlorine? More of the blue residue was dried at 100°, then heated upon a platinum-foil. Great volumes of ammonium chloride were expelled, leaving pale yellow coloured tungsten trioxide. An analysis of a portion of the dry, bluish material was made, when 5.48 per cent of NH_4 and 9.65 per cent of Cl were found. The presence of this amount of foreign substance could only be accounted for on the assumption that in the liberation of tungstic acid from ammoniacal solutions of ammonium tungstate with hydrochloric acid portions of the latter and of the ammonium chloride were so combined that no amount of washing would remove them. They are retained, and firmly, by the tungstic acid. Let those who question this examine the white, slimy residue which appears on attempting the solution of tungstic acid in ammonia. Most of us have quieted our consciences on this point by asserting that such residues are those "persistently insoluble paratungstates." If the solution from such residues be re-precipitated with hydrochloric acid, quantities of insoluble bodies again appear. These are beyond question ammonium chlorinated tungstic acid derivatives, which even prolonged boiling with concentrated acids will not change to the yellow acid. They merit further study.

The preceding experience emphasised the necessity of removing all the ammonium chloride in tungstic acid if the precipitation method of purification was to be pursued. This was done in the following way:—Two to 3 litres of concentrated nitric acid, diluted with water to half their volume, were heated in a large porcelain dish until it began to fume strongly, when 25 c.c. of pure hydrochloric acid and 3 kilograms of dry and fairly pure ammonium tungstate were added. Vigorous action set in, and volumes of decomposition gases escaped. The mixture was constantly stirred during the operation. As soon as the action diminished, 10 to 15 c.c. of pure hydrochloric acid were introduced at intervals. As the decomposition approached completion, the yellow tungstic acid lost its porous character, and collected as a heavy granular powder upon the bottom of the dish, but it was heated with occasional stirring for a period of from three to four hours. At the expiration of that time, there remained only tungstic acid, and nitric acid with traces of chlorine and ammonia. The tungstic acid was washed by decantation with pure distilled water until the tungstic acid suspended in the solution subsided very slowly, and the wash-water from it showed but a faint acid reaction. The subsided yellow-coloured acid was placed in a porcelain dish, hot distilled water was poured over it, and ammonia was conducted into the solution. As a rule, all of the acid dissolved, and there was at

the most a very small residue. Thus 45 litres of a saturated solution contained a residue which weighed less than 2 grms.

The ammonium paratungstate separating from such a solution showed the needles and plates characteristic of that salt. Only the first three fractions were preserved. They represented seven-eighths of the entire substance. The other portions were set aside. A second and a third treatment, as outlined above, was given the first three fractions, and when the salt, finally obtained, was subjected to the sodium carbonate test, allowing the solution to stand over-night, it remained absolutely clear. The mother-liquor from the salt, reduced to 5 c.c., remained colourless. One object in this long and baffling study had at last been obtained. We were the possessors of 700 grms. of pure ammonium paratungstate.

Three kilograms of impure ammonium paratungstate were decomposed by acids as described above, the operation being repeated five times, when the ammonium salt from the last decomposition responded admirably to the crucial tests. This salt disclosed none of the substances which were found accompanying the tungstic acid originally, hence the latter was considered pure, and was applied as will appear in subsequent paragraphs. However, before proceeding further it seems proper to direct attention to certain other experiences which possess interest and value.

The Residue obtained by Digesting Tungsten Trioxide with Sodium Carbonate.

Ammonium paratungstate, after three crystallisations, and when quite white in colour, was ignited in a platinum crucible. Two hundred grms. of oxide were obtained in this way, and were digested with a 2 per cent solution of sodium carbonate of excellent commercial quality. Quite a residue appeared. It was washed and dried. A portion, weighing 0.4712 gm., was digested with aqua regia. The insoluble part weighed 0.4309 gm., while the solution of the soluble constituents, weighing 0.0403 gm., was reduced to a small volume, diluted with water, and precipitated with ammonia. The iron weighed 0.0337 gm. as ferric oxide. Manganese and platinum were also found. The tungsten trioxide, when digested with hydrofluoric acid, lost 0.0149 gm., representing silica. Or, if the results be tabulated, they show:—

	Grm.	Per cent.
Weight of residue	0.4712	—
" WO_3	0.4160	88.28
" SiO_2	0.0149	3.16
" Fe_2O_3	0.0337	7.15
Manganese, platinum, &c. Undet.	—	—

98.59

Even pure sodium carbonate will not remove all of the impurities, although it may serve to test the purity of the oxide as to the iron, &c., which may be present.

Ignition of Ammonium Paratungstate.

The ignition of this salt in platinum vessels, as ordinarily conducted, contaminates the trioxide with platinum. To minimise this contamination a platinum crucible was fitted tightly two-thirds of its length into an asbestos board. A platinum-wire shaped into a tripod was set upon the bottom of the crucible. A smaller platinum crucible was supported by the tripod. Into the latter were introduced from time to time not more than from 2 to 3 grms. of ammonium tungstate. A red heat was applied to the outer crucible. The ammonia was expelled in the course of half-an-hour, when the crucibles were covered with an inverted porcelain lid, it being lifted from time to time to admit air. Constant weight was obtained in two hours. This procedure gave the best results which could be gotten by the use of platinum crucibles. While the oxide is cooling it should be protected from all reducing atmospheric dust, because the hot oxide is extremely sensitive to the action of such substances. This is evident from the following:—A platinum-rod previously heated in a flame

and applied to the hot oxide produces no change, but if the rod be touched quickly to the skin and then laid on the hot oxide, a green spot will appear at the point of contact.

The efforts to substitute silver and gold crucibles for those of platinum demonstrated that these metals, too, were appreciably absorbed by the oxide. Porcelain crucibles were used, notwithstanding the absorption of silica, which would of course become greater as the time of ignition was prolonged and as the heat was increased. Further, the oxide in immediate contact with the porcelain invariably showed a green colour. The glaze of the crucible always indicated etching. With an unglazed crucible the action was not so evident, hence the contamination was not so great, and the most satisfactory results were gotten by setting the unglazed porcelain crucible in a platinum crucible and bringing about the ignition of the salt in this double-walled chamber. The colouration of the surface of the oxide was extremely slight. Experience, however, eventually showed that the best course to pursue consisted in digesting the ammonium paratungstate directly in a porcelain casserole with pure nitric acid and a few c.c. of hydrochloric acid until it was completely decomposed, and the ammonia and hydrochloric acid were destroyed. When the tungstic acid was evaporated to complete dryness, it showed a rich orange-yellow colour. It was transferred to an unglazed porcelain crucible, and there ignited gently for half-an-hour. This may be done over a direct flame, the crucible being covered with an inverted porcelain lid. Any enclosed nitric acid was expelled by the gentle heat, and the weight soon became constant. The resulting tungstic oxide had a uniform yellow colour. Green was absolutely absent. This procedure eliminated the reduction caused by the ammonia, and it may be added that by its use glazed crucibles were employed every day in similar ignitions for several weeks without showing the least etching or corrosion of the surface.

Having at last gotten pure salt and pure oxide, the question arose as to what method should be adopted in the determination of the atomic weight of the metal. The method proposed by Taylor (see *ante*) was new. The results he obtained were with material not especially purified, yet their fair agreement pointed to the possibility of arriving at a definite value with the pure substance, such as was now available. Preliminary trials were executed according to Taylor's suggestions, using glass apparatus just as he had done, and drying at 400° to constant weight. The weighings were all made on the same day and under uniform conditions. The main purpose was to ascertain whether concordance in results could be realised. The results in the subjoined table show the opposite:—

	Na ₂ CO ₃	WO ₃	CO ₂	Atom. weight.
	Grms.	Grms.	Grms.	
1.	5.9	2.45645	0.16775	183.07
2.	5.6	2.72292	0.51785	183.36
3.	5.5	3.32953	0.63288	183.48
4.	4.7	3.96720	0.75473	183.29
5.	4.0	3.44944	0.65489	183.75
6.	4.1	3.41273	0.64796	183.74
7.	4.8	6.10309	1.16087	183.32
8.	3.9	6.39735	1.21644	183.39
9.	3.5	2.17150	0.41332	183.40
10.	3.1	1.57903	0.29966	183.85

The trioxide used in Experiments 1 to 4, inclusive, was obtained by gently igniting the ammonium salt in a porcelain crucible. That used in Experiments 5 and 6 was strongly heated in a porcelain crucible. In 7 and 8 the ammonium tungstate was heated for one hour in a double platinum crucible. The oxide in Experiment 7 had been heated two hours in the same kind of crucible, while in Experiment 10 the ignition continued for two hours in the double platinum crucible. The gradual rise in the value to 183.85 by protracted heating could surely not be due to the expulsion of volatile matter, for there was no change in weight after the first hour of ignition in the double crucible. Evidently the oxide absorbed impurities which led to the

rise in the atomic weight. Accordingly, samples of ammonium paratungstate were ignited under conditions as nearly similar as possible in crucibles of platinum and of porcelain. The values from the oxide in the crucibles of porcelain were higher than those from the oxide made in platinum crucibles, showing in all probability that the oxide took up more foreign material from the porcelain than from the platinum. Therefore the mere ignition of the ammonium salt in vessels, such as have been described, drew in sources of error. These would, of course, have to be eliminated if the method was to be tested upon its own merits. It was sought to accomplish this by igniting thoroughly dry ammonium paratungstate, and ascertain the loss (water and ammonia) sustained by different amounts, which resulted in discovering that the percentage of volatile matter could be obtained to within less than 0.01 per cent, which would answer for the purpose of atomic weight determination. And therefore, in the actual experiments, the ammonium paratungstate was weighed out directly into the flask, it being only necessary to make the proper calculations to arrive at the amount of trioxide which was then used. Six determinations were made; the results in the atomic value varied from 183.4 to 183.81. The early explanation for the lack of concordance, if the method was not faulty, would be to suppose that the action of the soda upon the glass would withdraw varying amounts of silica, and there would follow, of course, the liberation of corresponding amounts of carbon dioxide. If this really occasioned the error, it was hoped that the substitution of a platinum bulb, similar to the glass vessel, would lead to success. This was done. The experiments were performed as before, with slight modifications where it was considered advisable and advantageous. The atomic values in a series of five trials ranged from 182.85 to 183.64. Patient search was made for the reason, every step being tested repeatedly, until eventually the conclusion was forced upon us that carbon dioxide, in varying amounts, was disengaged through the decomposition of the sodium carbonate in the final drying. Jacquelin (*Yahresb.*, 1860, p. 116; *Ann. Chem.*, [4], xxviii., 86; and *Ann. Chem.*, [3], xxxii., 205) showed that this salt loses from 0.03 to 0.05 per cent in weight at 400°, and other observers have shown that the loss continued with the length of the period of ignition and with the temperature. Here, then, was a serious defect in the method which would explain why the values found were low, and why they differed so widely. The attempts to correct this weak point proved futile, so that the method, having had a thorough trying-out, was abandoned after months of arduous work.

It was hoped that perhaps a normal silver tungstate might be made, which after solution in potassium cyanide could be electrolysed and the value of tungsten obtained from a comparison with the precipitated silver. Fifteen experiments were made. In one series (the best) of five experiments the results varied from 184.00 to 184.39. It was found, after much search, that there could be no certainty as to when a normal salt was really in hand. Washing and drying, even when performed with the utmost care, occasioned a change in the character of the salt. The method was discarded.

An effort was also made to obtain a cadmium salt of definite composition. Much time was given to it, and experiments were made in the electrolysis of bodies believed to be uniform in composition. The atomic values ranged from 181.90 to 185.71.

Having subjected three new methods to vigorous tests in our efforts to solve the problem along new lines, and having found them utterly deficient, the hope still remained that possibly some of the earlier methods might with pure material give satisfactory results. The writers felt, without meaning to reflect in the slightest upon earlier investigators, that their material possessed the merit of superior purity; and if that were really the case, older methods, simple in principle and easy of execution, might well be expected to give concordant values. Of the 175 experiments made by the entire corps of previous investigators, there is but one short

series, namely, that of Pennington and Smith, in which there is that degree of concordance which is desirable and necessary in fixing the atomic value of any element. Splendid as is the work of Schneider, worthy as it is of high praise, there still remains the fact, not to be pushed aside, that between the minimum and maximum values there is a difference of more than a unit. The atomic value given by Schneider, Hardin, and others for tungsten is 18.4—the mean of very widely differing series. Cognisant of these facts, with faith in the greater purity of our material, steps were taken to repeat several older procedures.

(To be continued).

THE CONSTITUTION OF THE AMMONIUM COMPOUNDS.*

By JOHN CANNELL CAIN, D.Sc., M.Sc.

(Concluded from p. 41).

THE constitution of the metal ammonium compounds is sufficiently indicated by the formulæ $H_3N = ClAg$, $H_3N = ClCu$, $H_3N = ClPtCl$, NH_3 for the compounds of ammonia with the chlorides of silver, copper, and platinum respectively.

The correctness of this theory is rendered the more probable by the ease with which it explains the existence of the isomeric quaternary ammonium salts, to which reference has already been made. The stereochemical configuration of ammonium chloride and its substitution products, according to the usual ammonium theory, presents a special difficulty, owing to the fact that no symmetrical solid geometrical figure with five corners exists. In order therefore to arrive at a space formula, it became necessary to assume that certain valencies attached to the nitrogen atom are arranged in special directions. This is obviously a very grave assumption, and one which, of course, has no parallel in the very simple configuration of the carbon atom. In this way has been developed the cubic formula of van't Hoff, the double tetrahedron of Willgerodt, and the square pyramid of Bischoff. If we, however, accept the formula which is here presented, no new assumption has to be made in order to arrive at a space configuration. The nucleus $N = Cl$, instead of a carbon atom, is supposed to be at the centre of a tetrahedron, and we have—

The number of possible isomers is shown by the accompanying table.

General formula.	No. of isomers.	Formulæ of isomers.
NAAAACl	1	$A_3N = ClA$.
NAAABCl	1	$A_3N = ClB$, $A_2BN = ClA$. (a)
NAABBCl	2	$A_2BN = ClB$, $AB_2N = ClA$.
NAABCCl	3	$ABCN = ClA$, $A_2BN = ClC$, $A_2CN = ClB$.
NABDCCl	4	$BCDN = ClA$, $ACDN = ClB$, $ABDN = ClC$, $ABCN = ClD$. (b)

(a) These would be the formulæ of Kipping's hyridramine salts (*loc. cit.*).

(b) Three of these have been prepared in the case of the phenyl methyl allyl benzyl ammonium iodides; two optically active (Pope and Peachey, *loc. cit.*) and one inactive (Wedekind, *loc. cit.*).

The corresponding formulæ for acids other than hydrochloric are easily written.

The formula for tetramethylammonium iodide, viz.,

$(CH_3)_3N = ICH_3$, also explains its reactions much better than does the usual one (compare Armstrong).

The fact that a comparatively small number of isomers indicated by the above formulæ exists, is to be expected, for the isomers would in many cases differ greatly in stability. There would be a "stable" and a "labile" form, and often the labile would pass into the stable form so quickly as to prevent its isolation.

The ammonium theory has been freely used in the past in order to arrive at a formula for analogously constituted bodies; thus we have the phosphonium, arsonium, stibonium, sulphonium, oxonium, and diazonium compounds. We should, in view of the new theory, write the general formulæ $H_3P = ClH$, $H_3As = ClH$, $H_3Sb = ClH$, $H_3S = ClH$, $H_2O = ClH$, corresponding to $H_3N = ClH$. The diazonium salts—which are now considered to be derived from, e.g., aniline hydrochloride, by the replacement of three hydrogen atoms by one nitrogen, thus $C_6H_5N.Cl \rightarrow C_6H_5N.Cl$

(a mode of representation which does not account for the explosive nature of these compounds)—would be better written, in my opinion, as follows:—

resembling the formulæ of the azoimides,—

This mode of representation of the diazonium salts resembles both the older formula of Kekulé and the later one of Blomstrand in several important respects.

In Kekulé's formula, $C_6H_5.N = N.Cl$, the double linking between the nitrogen atoms shows a close analogy to the azo-compounds, and the position of the chlorine atom easily explains the formation of hydrazines, thus—

The Blomstrand formula, on the other hand,

shows the presence of pentad nitrogen, and is analogous to the existing ammonium theory. It is difficult, however, to explain the reduction to hydrazine by this formula,—

The new formula,—

explains the transition of a diazonium salt into a syn-diazo compound, thus—

avoiding the change of linkage necessary according to Hantzsch (*loc. cit.*, p. 45),—

and provides an easy representation of the hydrazine formation,—

* From the *Memoirs and Proceedings of the Manchester Literary and Philosophical Society*, 1904, xlviii., No. 14.

The diazotisation process is written—

the complex ion,—

being transformed into the ion—

thus, in the case of aniline, we have—

and sulphanilic acid—

The other reactions of diazonium salts, as well as those of the phosphonium, arsonium, &c., compounds, are similarly written.

NOTES ON GRAVITY AND CHEMICAL ACTION.

By W. P. DREAPER, F.I.C., F.C.S.

SINCE the days of Newton and the discovery of the law of gravity, the nature of this force has always been a subject for speculation and theory.

"The reason of these properties of gravity I have not as yet been able to deduce, and I frame no hypothesis," said Newton; and again, "gravity must be caused by an agent acting constantly according to certain laws."

Speculation and experimental science have since been occupied in trying to discover the nature of this universal force. The names of Mohr, Du Bois Reymond, Huyghens, Secchi, Le Sage, and others are closely connected with this subject.

All modes of action seem to be propagated radially from a centre in progressive oscillations in an elastic media. It is natural, therefore, to look in some such direction for the physical cause of gravitation. But all the theories which run on these lines are open to the objection that gravity acts instantaneously. Le Sage's theory assumes, on the other hand, that all space is constantly traversed by streams of infinitely small particles moving in all directions and with extreme velocities. Any two bodies acting as screens to these particles will protect each other from a certain number of impacts. These bodies are consequently driven towards one another. Clerk Maxwell's objection to this theory seems to be fatal to its acceptance. If one, however, substitutes "lines of force" for "ultramundane particles" his objections perhaps have not the same force. With this modification it seems possible to explain Shellbach's experiments, since re-discovered by Prof. Guthrie, on the grounds that the vibrating disc interferes with these lines of force. The latest idea of Prof. J. J. Thomson, that these lines are not imaginary but actually exist, also supports this view. It is perhaps unnecessary to draw attention to the other theories which have from time to time been brought forward. They have not received much support from modern thinkers.

In bringing forward the following theory I derive a certain amount of support from the fact that there is some evidence that Newton himself regarded gravity as a secondary phenomenon. Of such a nature is my theory.

Gravity in the past seems to have been regarded as a direct force, only differing from electrical or light phenomena in the fact that it acts instantaneously. All other

forces that we know of take a measurable time to traverse the ether space. The idea is here put forward that gravity is not a direct force in this sense of the word. This overcomes the difficulty of bringing such a constantly acting force into agreement with the theory of the conservation of energy.

The proposed theory stated in terms is as follows:— Gravitation is the result of the sum of all the forces, here collected under the term energy, passing or desiring to pass from one body to another through a resisting medium. This can be translated into a direct pull. The object of this transfer is to establish an equilibrium of force in space. This probably means the physical death of matter, the breaking down of the atom into its ultimate state, the establishment of a universal condition of rest. It is unnecessary, however, to assume that this condition will ever be reached, as explained further on.

We have recently obtained some idea of the energy stored up in the radium unit, and the result expressed in ordinary standards is immense. We also know that there is a gradual "leakage" leading to the breaking down of the complex-unit. These well-known facts are simply noticed, in passing, as showing the relation of this theory to the "New Chemistry." According to this new theory, the tendency to reduce the intervening space between two bodies, in order that this may take place more readily, is what we call gravity.

It is perhaps necessary from this view to regard all energy as kinetic. The almost perfect elasticity of the ether also enters into the question as an important factor.

It is necessary to offer some explanation why, if such action takes place, bodies do not discharge their available energy on contact, and then, if they still exist as matter, fall apart. It is put forward that, as the ether is not perfectly elastic, actual contact never takes place. There is always a thin film of ether left between the bombarding units, and this is sufficient to prevent the discharge of energy. This effect is seen in the case of bouncing soap-bubbles, where air forms the cushion. The air must be under an electric strain for the bubbles to coalesce.

The internal force state of the atom would also under this theory be explained. The action of the inter-atomic particles to a common centre shows that they, too, are influenced by some such attraction; and if this theory be correct they, too, have energy to distribute. It is this that keeps them revolving about a common centre, making up in their total effect the complex or tiny system which we call an atom. This corresponds perhaps to the phase taken up in their turn by molecules, producing what we term the crystalline state. Some such law of movement, be it vortex or otherwise, determines the atom as we know it. According to the above theory, two units approaching each other will ultimately meet; but it is contended that this will never actually take place, because the ether at the speed at which they travel is not perfectly elastic, and a film is always left between the units. Before this can be broken through, the units have separated again, and are under other influences. This takes place before the internal conditions of the unit can be disturbed. In the case of radium it is just possible that the time period is sufficient to allow a slight internal rearrangement of the atom, due to this outside influence, and that this is the cause of the breaking down of the complex unit. This may also apply in some other cases, but to a lesser extent, explaining such a phenomenon as the "Russell effect."

This constant play of forces may also give rise to the vibratory motion of the atoms and molecules in their attempt to break up the complex or vortex in the above mentioned way. This action would also be influenced by the interference of external energy, in the shape of vibrations in the ether itself (heat, electricity, &c.). Accepting the vortex theory, there is no need to assume that the ether is not perfectly elastic. The whirl of the units would itself explain the repelling action. I prefer, however, the former explanation as offering the lesser difficulties.

From this point of view the ordinary molecule is able to

hold its own in this constant bombardment, because of some force common to atoms of a definite nature which connects them up into whirling groups which are, under normal conditions of formation, stable. Chemical reaction, depending on actual contact by solution, pressure, or otherwise, and producing a rearrangement of the atoms, depends on this central molecular force-action being upset by a modification of the ether state surrounding the unit. This must be radical enough to upset the molecular system, but not the closer working system of the atom.

No force that we know of can disturb the internal arrangement of an atom of, say, gold or silver, but, as is well known, some internal or external force is able to do this in one case at least. Arguing from the above theory, it is suggested that it is only necessary to bring about the required state of the surrounding ether in the other cases to accomplish the same end.

Assuming also that the atom has a definite pull corresponding in some way to its system, this in a molecule will determine its external form, be it a whirling complex or otherwise.

Examine the case of the earth and sun from the point of view of this theory. The earth is kept in its course by the fact that the resistance to the flow of energy would be increased if the distance between them was greater, and this would naturally increase as the square of the distance. This is translated into a direct pull, which somehow directly balances the centrifugal force. This extraordinary balancing of these two forces, gravity and centrifugal force respectively, must surely indicate that they are both factors or functions of some unknown but common phenomenon. Otherwise their action and stability is unthinkable unless we are willing to accept the idea of a higher controlling and constant force.

The elliptical path of the earth round the sun would under ordinary circumstances indicate that these two forces, or at least one of them, alternates in phases corresponding to the time duration of progress as expressed in the revolution of the earth.

The effect of attraction, due it is contended to a similar state of affairs, is seen in the case of electrified pith balls. Here they approach one another by distance action to equalise their energy. Why should not gravity be of the same order as this, with the difference that some counter-acting agency prevents the actual "discharge" taking place?

Matter may be the result of the breaking up of the ether into particles of plus and minus values. This is not inconsistent from a mathematical point of view, as their total value in energy would still = 0. Matter simply indicating a difference in potential state of the ether, plus or minus, as the case may be; but for every plus unit there would be a minus one somewhere. In this way the total energy expressed mathematically would not be increased or decreased by what we term the presence of matter. There might be some connection between this and the optically opposite values (+) of some compounds. Nickel and cobalt with the same atomic densities or attractions may have respectively plus and minus values from this point of view.

It is of course the same action which produces the solid state; the space occupied by a certain number of molecules being under existing conditions the least possible permitted by this bombarding action and the vibratory state of the ether. Expansion on heating may also be explained on the assumption that ether is less elastic when in a state of increased vibration. This is the cause of the greater space between the molecules and consequent expansion of the substance.

It is interesting to note in passing the influence of this theory on magnetic phenomena. Assuming that there is a constant flow of energy through space, and that the magnetised iron or the ether which surrounds it is in a state of strain, a better path is offered for this flow of energy, and that consequently this space becomes + to the surrounding district. In other words, more energy streams through this space. If another piece of iron is brought into

this + area, its state will also be modified (as we know), and it would enter into the conducting system and resist any change of position that would break the stream of surplus energy. This explanation overcomes the difficulty of bringing magnetic attraction into line with the theory of the conservation of energy. Some such theory may also account for induction currents. Radium may act in some similar way; the surplus energy being indicated here by increased temperature. This unusual and active state of the ether may be the cause direct or indirect of the breaking down of the radium molecule.

By analogy we might argue that some such state of increased vibration of the ether in the intermolecular space of, say, a silver salt dissolved in a solution which is conducting an electric current, may just determine the difference between a "simple" and a "compound" state for the silver unit; the result of this being deposition of the metal. This extra vibration, by reducing the co-efficient of elasticity of the ether, might tend to separate the atoms making up the molecule, and neutralise in some way the intermolecular attraction. At the other pole it may be that in some way this action is reversed in order that the energy in the system may still = 0.

Surface tension and dissociation in liquid state as examined in the light of this theory are interesting, but the results obtained are reserved for another occasion. Also the bearing of this theory on the idea that energy is only radiated discriminately, and not in all directions or in a promiscuous manner.

The colloidal state taken up by some bodies might possibly be explained in the following way:—The attraction of the molecules of a colloid for each other in the presence of a "dissolving" liquid is not sufficient for the substance to take the solid form. From this point of view a colloid is not a solution at all. Its molecules are so divided, by the interposition of the liquid, that they occupy increased bulk. This gives rise to the swelling action; the pull of gravitation still holds, but to a modified extent. For example, water may be loosely held in combination, or may simply intrude itself, causing the swelling. Gravity still acting, however, the molecules resist parting, and this modified pull is of an elastic nature. On the gradual removal of the "solvent" this loosely held water goes off with the ether, and the substance gradually resumes its normal condition. From a physical point of view a colloid, in the presence of a liquid capable of penetrating it in this way, becomes less rigid, more elastic. Heat may in some cases encourage this action to such an extent that this separation, as measured by the viscosity of the mixture, may be greatly increased. The appearance of the mixture may almost approach that of a solution.

A colloid is never really soluble, but the degree of "hydration" varies with different substances.

The deposition of dye matter in a fibre (colloid) may be due to the fibre substance interfering with this action and reducing the "hydration" of the substance accordingly. This would lead to the deposition of the dye in the substance of the fibre; the rate of precipitation and fastness depending upon factors governing the "solution" and "precipitating" action respectively.

It follows also that the substance dyed must also be a colloid. It, too, must swell up to allow penetration of the liquid carrying the colloid dye or mordant. Perhaps in some such way the explanation of the decomposition of basic dyes may be discovered, the colloid playing the part of the fishing-net, and allowing particles of a certain size to pass with ease, but preventing others. This action, combined with the "fibre action," may be enough to decompose the basic dye with precipitation of the base.

The difference between a colloid and a non-colloid might therefore be a measure of their respective molecular attractions in the dry state, modified by the nature of the "soluting" liquid.

This theory on the face of it gets over the difficulty that gravity acts instantaneously, and does not obey the laws of reflection, refraction, &c. In this way it stands in

advance of the "direct" theories. It is also unnecessary to assume, as in Le Sage's original theory, quite a new state of affairs in the universe to explain its action. It is put forward, however, with the full knowledge that it, in common with all other theories of a speculative nature, may hardly give a correct impression of the true state of affairs as represented by absolute fact. In bringing it forward, and also as an alternative the modified Le Sage's theory, I do so with this full knowledge.

THE USE OF A SOLUTION OF OLEATE OF POTASSIUM FOR THE DETERMINATION OF THE HARDNESS OF WATERS.

By L. W. WINKLER

In the *Zeitschrift für Angewandte Chemie* (1902, No. 31) M. Grittner published a paper in which he declared that the method I had described (*Zeit. Angew. Chem.*, 1901, p. 82) for the determination of the lime and magnesia in waters by means of a solution of oleate of potassium was useless, and that it gave entirely erroneous results when the water contained magnesia. I agree that this method is not applicable when the greatest accuracy is required, or with waters in which the magnesia hardness is greater than the lime hardness; but I will show that this process has considerable merit, even with waters containing a large amount of magnesia, if we operate at sufficient dilutions. Waters rich in magnesia should be diluted until their total hardness does not exceed 5° (German). M. Grittner considers that the froth produced from the titration of the lime is never so characteristic as that which forms when we are dealing with magnesia. I have only been able to observe the contrary so long as the magnesia hardness was not greater than that of the lime. But to do away with this possible inconvenience, No. 1 reagent was improved by the addition of ammonia. The formula we now recommend should therefore be as follows:—Dissolve 6 grms. of pure hydrate of lime and 100 grms. of crystals of Seignette salt in about 250 grms. of water; add about 100 c.c. of ammonia at 10 per cent, and make up the bulk to 500 c.c.

To further examine this new reagent and the method itself, we undertook a fresh series of determinations of hardness. To obtain results as free as possible from errors, the measurements were made by chemists who had not previously used the method. Solution No. 1 was not diluted; Solution 2 was doubled in volume, as was also Solution 3; Solution 4 was tripled; and Solutions 5 and 6 were quadrupled. The results obtained were as follows:—

TABLE I.

Solution No.	Hardness of the solution.			Hardness found.		
	Lime hardness	Magnesia hardness	Total hardness	Lime hardness	Magnesia hardness	Total hardness
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
1.	3.50	2.50	6.00	3.60	2.57	6.17
				3.75	2.74	6.49
				3.70	2.55	6.25
				8.00	4.80	12.80
2.	8.00	4.00	12.00	8.10	5.40	13.50
				7.84	5.00	12.84
				7.58	7.32	14.90
				8.60	7.12	15.72
3.	8.00	8.00	16.00	8.50	6.98	15.48
				15.15	6.99	22.29
				15.30	7.02	22.32
				15.06	7.77	22.83
4.	15.00	6.00	21.00	16.40	11.20	27.60
				16.84	10.48	27.32
				16.76	11.88	28.64
				21.20	11.80	33.00
5.	16.00	10.00	26.00	20.60	13.60	34.20
				20.32	13.40	33.72
6.	20.00	11.00	31.00			

We see that, in these cases, the results are close, and evidently they would have been better after a little more practice; besides, in none of these cases was the magnesia hardness higher than that of the lime.

The following experiments, carried out with great care by M. Kopper, show the great accuracy that can be obtained, even when the magnesia hardness is high. Solution 1 has not been diluted, Solution 2 was diluted four times, Solution 3 six times, Solution 4 twelve times, Solution 5 ten times, and Solution 6 five times. The results obtained are given in Table II.

TABLE II.

Solution No.	Hardness of the solution.			Hardness found		
	Lime hardness	Magnesia hardness	Total hardness	Lime hardness	Magnesia hardness	Total hardness
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
1.	4.00	3.00	7.00	4.09	2.83	6.92
				4.07	2.62	6.69
				4.10	2.60	6.70
				10.52	10.68	21.20
2.	4.00	10.00	14.00	4.10	10.60	14.70
				4.07	10.24	14.31
				4.07	10.24	14.31
				27.06	25.00	52.06
3.	4.00	28.00	32.00	27.84	25.02	52.86
				27.54	26.16	53.70
				28.02	28.20	56.22
				28.56	30.18	58.74
4.	28.00	28.00	56.00	28.68	27.06	55.74
				49.80	34.00	83.80
				49.00	33.70	82.70
				49.30	35.20	84.50
5.	50.00	31.00	81.00	6.65	20.75	27.40
				6.85	21.25	28.10
				6.85	21.15	28.00
6.	5.00	22.00	27.00			

The artificial waters examined did not contain any carbonic acid. We have therefore examined the influence of carbonic acid on the results obtained by this method. To effect this, we examined the tap-water of Buda-Pesth before and after saturation with carbonic acid. The results obtained are given in Table III.

TABLE III.

	Without carbonic acid.			With carbonic acid		
	Lime hardness	Magnesia hardness	Total hardness	Lime hardness	Magnesia hardness	Total hardness
1.	7.44	7.48	7.50	7.66	7.60	7.63
2.	2.80	2.81	2.86	2.91	2.99	2.99
3.	10.24	10.29	10.36	10.57	10.59	10.62

As is seen, the presence of carbonic acid, even in large quantities, has little influence; therefore it is unnecessary to get rid of it as a preliminary precaution.

From the above results, I maintain that the method as modified gives good results. The harder and richer the water is in magnesia, the greater is the error; the softer the water, the greater the accuracy. The error is less than one degree with soft waters, two degrees with hard waters, and only a few degrees with very hard waters.

On account of its simplicity, the method can be recommended for the analysis of potable waters, since, from the hygienic point of view, an error of one or two degrees is of no importance. If the water is very hard, an error of a few degrees does not really matter, as the water is no longer potable. The unfavourable case in which the magnesia hardness of the water is higher than the lime hardness, at the same time both being high, is rare. So as to know roughly the proportion of magnesia present a qualitative analysis is made. After a preliminary trial of the total hardness, a second test is made on the lime with water diluted to 5°.—*Zeitschrift für Angewandte Chemie*, 1903, p. 200.

CORRESPONDENCE.

INTERNATIONAL ATOMIC WEIGHTS.

To the Editor of the Chemical News.

SIR,—The letter of Professors Sakurai and Ikeda, on the subject of International Atomic Weights, published in your issue of June 24, seems to require a reply. In order to avoid delay, which correspondence with other members of the committee would involve, I venture to make the reply personal. It therefore represents only my own views, expressed without consultation with others.

In the first place, the sub-committee have not argued in favour of the double standard. They have simply recognised an existing demand, and have thought it better to furnish the two sets of values, rather than to leave their calculation to individuals. It is true that in 1900 the larger committee on atomic weights registered a very decided vote in favour of the oxygen standard; but this was followed later by a strong protest from many chemists in Germany and Austria. In the *Berichte* for Dec. 4, 1901, a vote is recorded of 106 in favour of the hydrogen standard, to 78 for O = 16. In other countries a similar difference of opinion exists, less aggressive perhaps, but by no means negligible. The force of this opposition to the oxygen standard was recognised by Landolt, Ostwald, and Seubert in their report for 1901, in which they published a double table; and we have only followed the precedent set by them. We could not properly disregard the wishes of so many distinguished chemists, nor could we assume an agreement where no agreement exists, much as it is to be desired. As for Professor Ostwald's protest, that was promptly answered by Professor Seubert.

The tables published by the present sub-committee have been based upon those issued by Landolt, Ostwald, and Seubert, with only such changes as seemed to be absolutely necessary. The table based upon H = 1 is essentially that issued by the German committee in 1901, with the fewest possible alterations. The objections noted by Professors Ikeda and Sakurai are perfectly just, and represent the evident difficulties attending the use of a double standard. The adjustment of one table to the other is a matter of rather delicate judgment, and the appearance of inconsistency is not always easy to avoid. Just how far a given atomic weight is trustworthy is not certain, and recent researches upon nitrogen and iodine seem to indicate the need of a general revision of the tables in the near future. Sudden or radical changes in the atomic weights are evidently undesirable; but some alterations will have to be made. The recalculation of the hydrogen table may be necessary, however, without delay; and I shall recommend it to the other members of the committee. Final action will depend upon their desires.

With reference to the symbols Gl and Cb, adopted in the American version of our report, a few words seem to be needed. The name glucium and the symbol Gl have clear priority over beryllium and Be, and are favoured by the chemists of France. In England and America the usage is divided; so that here again no agreement exists. I much doubt whether France would accept a change from the older to the newer symbol. In the case of columbium and the symbol Cb, we have again the original nomenclature and notation. Columbium was discovered by Hatchett in 1801. Nearly forty years later Rose thought that he had discovered a new metal, which he named niobium. This proved to be identical with columbium, and the substitution of its name for that first given was wholly unjustifiable. As a matter of scientific nomenclature columbium and Cb are to be preferred.

The reports of the present sub-committee have been published in the journals of the American, English, French, and German chemical societies, and also in several other periodicals. This we have supposed to be an adequate report to the members of the larger body. To report to

over fifty chemists individually would involve much labour, and would seem to be superfluous. I shall, however, take pleasure in sending a copy of our next report to the representatives of the Tokyo Society, in order that it may appear in their journal also.—I am, &c.,

F. W. CLARKE,
Chairman International Sub-committee on
Atomic Weights.

United States Geological Survey,
Washington, D.C., July 12, 1904.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxviii., No. 26, June 27, 1904.

Cyanogen : Solubility and Polymerisation.—M. Berthelot.—The author examines the effect of a number of solvents on cyanogen. In all cases the reaction takes place over mercury, as this gas has no effect on the metal.

Cyanogen and its Action on Potassium Cyanide.—M. Berthelot.—The author operates with various concentrations of potassium cyanide dissolved in water and in alcohol. These solutions dissolve cyanogen rapidly at about 20°. The gas is decomposed and a brown precipitate formed. He finds that water, alcohol, and potassium cyanide cause the destruction of an indefinite number of molecules of cyanogen.

Distillation of a Mixture of Two Metals.—Henri Moissan and M. O'Farrelley.—During a series of researches on the boiling-points of metals, the authors came across examples corresponding to three types of distillation of a mixture of two liquids. Copper and lead behave, when distilled, as a mixture of partially miscible liquids, such as a mixture of ether and water. On the contrary, tin and lead behave as a solution of water and alcohol. Copper and tin resemble a solution of water and formic acid, and there exists in this case a constant temperature—very high, however,—at which the two bodies possess the same vapour tension. The laws which govern the fractionation of two liquids by distillation can be applied also to boiling-points of metals at a very high temperature.

Influence of the Combination of Non-saturated Radicles with certain Molecules on their Rotatory Power. Allylic Ethers of Borneol, Menthol, β -Methylcyclohexanol and Linalol.—A. Haller and F. March.—Continuing their research on rotatory powers, the authors measure the increase in the specific rotation of certain active alcohols when combined under the form of the ether oxide, $R-OCH_2-CH=CH_2$, with a non-saturated molecule like allylic alcohol.

The Red and Yellow Varieties of Thallous Iodide, and the Determination of the Normal Point of their Reciprocal Transformations.—D. Gernez.—The author finds that the velocity of transformation of the two varieties of thallous iodide one into the other becomes less and less as the temperature approaches the normal point of transformation, at which point it is zero. Experiment proves this temperature to be about 168°, i.e., 22° less than Heberling's number.

Thallous Nitrate and Nitrite.—V. Thomas.—The decomposition of thallous nitrate towards 450° produces nitrous anhydride and a well crystalline sesquioxide without an appreciable formation of nitrite. The nitrite decomposes itself in an analogous manner, giving principally nitrous anhydride and thallium protoxide. It seems that the stability of this nitrite is decidedly less than the stability of potassium nitrite. It is also an interesting fact

that thalious nitrate can be partially volatilised without undergoing decomposition.

Total Synthesis of Rhodinol, the Characteristic Alcohol of Essence of Roses.—L. Bouveault and M. Gourmand.—The authors apply the method of synthesis recently described by one of them and M. Blanc to ethyl

geraniate,

This latter substance has been recently synthesised by MM. Barbier and Bouveault. The process is then described by which it is transformed into rhodinol.

Two Homologues of Pyrocatechin.—R. Delange.—The author prepares two homologues of pyrocatechin, ethylpyrocatechin and isopropylpyrocatechin, by methods analogous to those by which he has already obtained propylpyrocatechin.

A New Class of Ether Oxides.—Marcel Descudé.—When hydrochloric acid acts on an aqueous solution of methanal, and the product of this reaction is treated with alcohol, the following compound is formed:— $\text{C}_2\text{H}_5-\text{O}-\text{CH}_2-\text{O}-\text{CH}_2-\text{O}-\text{C}_2\text{H}_5$, which the author calls dioxymethyldimethylether, a compound boiling at $102-106^\circ$, and of specific gravity 0.864. When methyl alcohol is used, dioxymethyldimethylether is produced, boiling at $106-108^\circ$, and with density 0.959. This body, when in the state of vapour, forms with oxygen a mixture which explodes violently at a red heat. The same phenomenon taking place with the ethylic derivative, but with less intensity.

Methylarsenic.—V. Auger.—Methylarsenic, $(\text{CH}_3\text{As})_4$, is produced when a solution of sodium methylarsinate, sodium hypophosphite, and dilute sulphuric acid are heated together on a water-bath:— $2\text{PH}_3\text{O}_2 + \text{CH}_3\text{AsO}_2\text{H}_2 = 2\text{PH}_3 + \text{CH}_3\text{As} + \text{H}_2\text{O}$. The methylarsenic is a pale yellow oil.

Certain Mixed Phosphorus Derivatives of Hypophosphorous Acid.—C. Marie.—The author prepares a number of mixed acids corresponding to the general formula $\text{R}.\text{CH}(\text{OH})\text{R}'\text{CH}(\text{OH})\text{PO}_2\text{H}$.

Ammoniacal Additive Compounds of Rosaniline.—Jules Schmidlin.—The author prepares a number of additive compounds of rosaniline, and concludes from his experiments that the salts of rosaniline represent non-saturated molecules. The non-saturated functions which they contain are chemically neutral, and can be saturated either by bases or acids. It may be concluded in this case that the non-saturated element ought to be a neutral element, and therefore, in this case, carbon. The limit of saturation seems to be reached with 4 molecules of hydrochloric acid gas or 4 molecules of ammonia.

Bulletin de la Société Chimique de Paris.
Series 3, vol. xxxi., No. 1.

Modifications of the Procedure in Estimating Nitric Nitrogen by the Pelouze-Fresenius Method.—Léon Debourdeaux.—The apparatus used is similar to that of Fresenius, but it comprises an additional condenser, to prevent the concentration and loss of nitric acid. The sample containing the nitrate is placed in the flask, and carbonic acid passed through to drive out the air. The ferrous solution is then passed in, by means of a pipette, through the gas tube, and heat is then applied and maintained until decoloration is complete. The flask is then allowed to cool, still keeping up the current of gas. The tubes are washed with boiled distilled water, and the remainder of the ferrous salt left in solution titrated with a standardised solution of permanganate of potassium. Extraneously close results are found by this method.

A New Method for the Volumetric Estimation of Nitric Nitrogen.—Léon Debourdeaux.—Already noticed.

Colloidal Silver.—A. Chassevant.—Already noticed.

Preparation and Properties of Pure Colloidal Silver.—A. Chassevant.—Already inserted in full.

Action of Organo-magnesium Derivatives of Epichlorhydrine.—André Kling.—As a result of his experiments, the author finds that the organo-magnesium derivatives in the cold react on the ether oxides, giving a compound which, though immediately destroyed by water, furnishes a product resulting from the fixation pure and simple on the oxide of the hydracid from which the organo-

reaction does not take place with the ketones, and thus enables us to differentiate between a ketonic oxidised compound and the oxidic oxygen.

Action of Organo-magnesian Derivatives on Acetone and its Ether Salts.—André Kling.—Already noticed.

Action of Secondary Bases on the Phenolic Carbonates.—M. Bouchetal de la Roche.—The secondary bases of the fatty series attack these carbonates fairly easily, though less energetically than piperidine or dimethylpiperazine. The aromatic secondary bases either do not react at all, or react with difficulty. Dimethylamine and dipropylamine, acting on different phenolic carbonates, have given the corresponding carbamates. The same was the case with dibenzylamine, but the return was bad. The author did not succeed in making diphenylamine react; it does not attack the carbonic ethers, even at 300° .

The Ureas of Piperidine.—M. Bouchetal de la Roche.—Already noticed.

The Organo-magnesium Derivatives of the Dihalogen Aromatic Hydrocarides in the Radicle.—Action of Carbonic Anhydride.—F. Bodroux.—Carbonic acid reacts on the bromides of parachlorophenylmagnesium and parabromophenylmagnesium, giving both a mono substituted benzoic acid and a dihalogen symmetric derivative of benzophenone. If we operate at the temperature of boiling ether, the latter compound dominates; if, on the contrary, we proceed at a low temperature, it is the substituted benzoic acid which forms in the greatest proportion.

Organo-magnesium Derivatives of the Mono-bromised Phenolic Acids.—Action of Carbonic Anhydride.—F. Bodroux.—The author describes the synthesis of anisic acid, paraethoxybenzoic acid, methoxy-2-naphthoic-1 acid, ethoxy-2-naphthoic-1 acid, and propoxy-2-naphthoic-1 acid. The last three are soluble in ether, benzene, acetone, chloroform, and sulphide of carbon, but not in ligroin, even when boiled. They are rapidly decomposed by boiling with a concentrated solution of hydrobromic acid for a few moments. CO_2 is given off, and an ether oxide of β -naphthol is re-formed, which, by the further action of the hydrobromic acid, becomes partially saponified in its turn.

Oxidation of Mixed Organo-magnesium Compounds.—Synthesis of the Phenols.—F. Bodroux.—Already noticed.

Some Compounds of Bismuth with the Oxybenzoic Acids.—Paul Thibault.—The author has prepared the paraoxybenzoate, the β -resorcyate, and the oxyalsicylate in the crystalline form. They all three have the properties of salts of bismuth, and it is to be noted that they can be only prepared by starting with the anhydrous oxide, the hydrated oxide being unattackable. The oxyalsicylate and the β -resorcyate are both stable in water.

Formation of the Azoids.—Reduction of Ortho-nitrobenzyl Ether Oxides.—P. Freundler.—Already noticed.

Comparative Research on the Essences of Geranium of Cannes.—P. Jeancard and C. Satie.—Not suitable for abstraction.

Action of Isocyanate of Phenyl on some Univalent Alcohols. (I).—A. Bloch.—The author has examined the action of isocyanate of phenyl on the alcohols with a large number of carbon atoms to see if the reaction took place under the same conditions as for the lower terms, and if the properties of the bodies obtained were identical with those of ethylphenylurethane. Except with cholesterol, he applied his experiments to the alcohols of the saturated series.

MISCELLANEOUS.

The British Association.—The following papers will be read, amongst others, at the forthcoming meeting of the British Association at Cambridge:—

"On Dynamic Isomerism," by Dr. T. M. Lowry (London).

"The Stereochemistry of Nitrogen," by H. O. Jones, M.A. (Cambridge).

"On Crystal Structure and its relations to Chemical Constitution," by Prof. Paul Groth (Munich).

"On the Velocity of Osmosis and on Solubility: a Contribution to the Theory of Narkosis," by Prof. Isidor Traube (Berlin).

"The Decomposition and Synthesis of Ammonia," by Dr. E. A. Perman (Cardiff).

"On the Energy of Water and Steam at High Temperatures," by Prof. C. Dieterici (Hanover).

"On the Active Variety of Chlorine," by D. L. Chapman and C. H. Burgess (Manchester).

"The Oxidation of Carbohydrates by Hydrogen Peroxide in the presence of Ferrous Sulphate," by R. S. Morrell and A. E. Bellars (Cambridge).

"Studies in the Dynamic Isomerism of the α - and β -Crotonic Acids," by R. S. Morrell and E. K. Hanson (Cambridge).

"A Suggested Explanation of the Phenomena of Opalescence observed in the Neighbourhood of Critical States," by F. G. Donnan (Dublin).

"Sur le Spectre du Soufre Dans la Photographie de L'etincelle des Mineraux," par Mons. le Comte Arnaud de Gramont de Paris.

"Mesoxalic Semialdehyde," by H. J. H. Fenton, F.R.S. (Cambridge).

"Note on the Influence of Radium Radiations on Atmospheric Oxidation in presence of Iron," by H. J. H. Fenton, F.R.S.

"A Reaction for Ketohexoses," by H. J. H. Fenton, F.R.S.

"A Colour Reaction for Methylfurfural and its Derivatives," by H. J. H. Fenton, F.R.S. and J. P. Millington.

"On the Pentavalent Nitrogen Atom," by Prof. Ossian Aschan (Helsingfors).

"Saponarin, a Glucoside coloured Blue by Iodide," by G. Barger (Cambridge).

"The Union of Hydrogen and Oxygen in Contact with a Hot Surface," by Dr. W. A. Bone and R. V. Wheeler (Manchester).

"The Constitution of Phthalein Salts," by Prof. Richard Meyer (Braunschweig).

"The Intensification of Chemical Action in the Neighbourhood of Hot Metals and other Surfaces," by G. T. Beilby (Glasgow).

"Reactions between Solid Salts," by G. T. Beilby.

In his Presidential Address to Section B, Prof. Sydney Young proposes to show that, in attempting to arrive at generalisations regarding the properties of substances, it is advisable in the first place to confine one's attention to compounds (or elements) in which molecular association is not believed to occur. He is considering shortly Kopp's speculations and researches on the boiling points of organic compounds in order to show that Kopp was misled at the outset by dealing with the alcohols, acids, and

esters, and he is suggesting a formula applicable without great error to all organic compounds of normal behaviour except the first two or three members of some homologous series. After touching on the question of molecular volumes Prof. Young considers the behaviour of organic compounds on admixture and the properties of mixtures, more particularly the vapour pressures and boiling points, the relative composition of vapour and liquid, and, lastly, the critical points of mixtures.

Institute of Chemistry of Great Britain and Ireland.

—**Pass List of the July Examinations.**—Of 23 Candidates who entered for the Intermediate Examination, the following 15 passed:—Leslie Hamilton Berry, Thomas William Cheke, Winifred Cox, B.Sc., Reginald Mead Filmer, Charles Gordon Gates, Harry Hurst, Vincent Herbert Kirkham, B.Sc., Jessie Mary Isabel Landon, B.Sc., Archibald William Mairet, Edwin Archibald Maskelyne, William Rest Mummery, Joseph Race, jun., Robert Robison, Robert Thatcher Rolfe, and Samuel Summerson. In the Final Examination for the Associate-ship (A.I.C.), of 8 who entered in Mineral Chemistry the following 5 passed:—David Allan, John Alexander Campbell, David Cowan Crichton, John Gatecliff, jun., B.Sc., and Charles James; one Candidate passed in Metallurgical Chemistry—Thomas Baker, M.Sc.; one Candidate passed in Physical Chemistry—Sydney Herbert Smith, Assoc.R.C.Sc.; of the 5 who entered in Organic Chemistry the following 3 passed:—Robert William Clarke, Bernard Furley Davis, and Edward Charles Martin, B.Sc.; and of 10 who entered in the Branch of the Analysis of Food and Drugs, and of Water, including Examination in Therapeutics, Pharmacology, and Microscopy, the following 5 passed:—Walter Kay Cheshire, B.Sc., Harold Deane, B.Sc., Leonhardt Erich Hinkel, Ernest Gabriel Jones, B.Sc., and Francis Langston Watt, Assoc.R.C.Sc. Two Candidates were examined for the Fellowship (F.I.C.) and both passed:—David Runciman Boyd, B.Sc., Ph.D., and James McLeod. The Examiners in Chemistry were Mr. Walter William Fisher and Professor George Gerald Henderson. Dr. Arthur P. Luff conducted the Examination in Therapeutics, Pharmacology, and Microscopy.

Compounds of Sulphurous Acid Gas with various Salts.—P. Walden and M. Centnerszwer.—With the object of establishing the constitution of the compounds formed by sulphurous acid with various salts, especially with the alkaline iodides, the authors submitted the products resulting from the action of this gas on iodide of potassium, one of which was isolated by Péchard, to a detailed physico-chemical examination (measurement of vapour tension, the curve of melting points, the curve of division into two layers by the elevation of temperature, &c.). From the observations made they were led to the following conclusions:—The melting point of pure SO_2 is -72.7° . The solution of KI in liquid SO_2 gives a deposit, below 0° , of yellow crystals of a compound having the formula $\text{KI}(\text{SO}_2)_4$ fusing at $+0.26^\circ$, in which the SO_2 appears to play a part analogous to that of ammonia gas in the ammoniacal chlorides of silver, for example. At lower temperatures, about -60° , a compound rich in SO_2 is deposited, having the formula $\text{KI}(\text{SO}_2)_{14}$, melting at 23° , and apparently having an analogous constitution. On the other hand, it has not been possible to detect the existence of a compound of the formula $\text{KI}(\text{SO}_2)_2$, by measurements of the vapour tension. The examination of the equilibrium occurring at high temperatures (about 100°) has enabled the authors to determine the higher limit of the existence of solutions of KI in SO_2 . In aqueous solution, a dilution of N/0.4 is sufficient for the complex compounds of SO_2 to be almost entirely destroyed, as shown by cryoscopic measurements. Sulphurous acid gas is more soluble in concentrated aqueous solutions of the alkaline salts, KI, KCNS, RbI, KCl, KBr, $\text{N}(\text{CH}_3)_4\text{I}$, than in water; NaCl is an exception. From these facts it appears that liquefied sulphurous acid, like the two ionising solvents already examined by the same authors

(water and ammonia), is capable of uniting with the binary salts giving complex compounds; these complex compounds appear to exist also in the saline solutions of sulphurous gas; for the sake of simplicity, and by analogy with the terminology used in organic chemistry, the authors propose to call these bodies sulphones; thus the compound $KI(SO_3)_4$ would be called iodide of potassium tetrasulphone.—*Zeit. Physik. Ch.*, vol. xlii., p. 432.

Research on the Dissociation of the Salts of the Heavy Metals. The Nitro-salts of Mercury.—H. Ley and K. Schäfer.—The limit between the acids proper and the neutral bodies which resemble them in some points, such, for example, as the formation of salts, is very difficult to fix. The theory of dissociation alone gives a precise delimitation in this respect; it reserves the title of acids to the bodies capable of forming hydrogen ions. In the same manner the salts are distinguished from the organometallic compounds by their electrolytic dissociation. From this point of view the authors have examined the nitro-salts of mercury, that is to say the mercuric derivatives of the amides and the imides. It has been long known that the dissociation of the mercuric salts depends essentially upon the nature of the bond uniting the metal and the radical. In salts in which this bond is effected by oxygen (the oxidised salts of mercury), the dissociation is very marked; on the other hand, when the bond of union is nitrogen, the dissociation is very feeble; hydrolysis, even at a high temperature is also very feeble; in short, the affinity of mercury for nitrogen is very great. The authors have confirmed these views by examining the decomposition of these nitro-salts by means of strong acids, and by the electrometric measurement of their dissociation. In this way cyanide of mercury behaves in quite a different manner to the imidised salts, from which we may reasonably conclude that the bond between the radical and the metal is not nitrogen but carbon, which has a greater affinity for the mercury than the nitrogen has.—*Zeit. Physik. Ch.*, vol. xlii., p. 690.

Peroxide of Hydrogen of Crystallisation.—Richard Willstätter.—The author has met with several salts susceptible of becoming united, on crystallisation, with a certain number of molecules of peroxide of hydrogen; alum, sulphate of alumina, borax, and acetate of soda are among these. The neutral sulphates of ammonium or sodium also give two exceedingly characteristic compounds. As they easily give up their peroxide of hydrogen (to ether, for example) they can be used in place of this body, as well as in the place of persulphates and percarbonates in a large number of cases, especially when we wish to introduce a definite quantity of peroxide of hydrogen. The compound $(NH_4)_2SO_4 \cdot H_2O_2$ is obtained by the evaporation, in the presence of sulphuric acid, of a solution of sulphate of ammonium and peroxide of hydrogen at 30 per cent. In this manner beautiful crystals are formed having an odour of ozone, efflorescing in air or *in vacuo*, but remaining unchanged in a sealed tube. When heated under reduced pressure a very concentrated peroxide of hydrogen is distilled off. The compound $Na_2SO_4 \cdot H_2O_2 \cdot 4H_2O$ is obtained in a similar manner; in a sulphuric vacuum it loses its water fairly quickly, and then its peroxide of hydrogen slowly.—*Berichte*, vol. xxxvi., p. 1828.

Equilibrium of Solution between Chloride of Silver, Oxide of Silver, and Solutions of Chloride of Potassium and Potash.—A. A. Noyes and D. A. Kohr.—The solubility of AgOH in distilled water, measured in the ordinary analytical manner, is $2.16 \cdot 10^{-4}$ molecules per litre; that of the iodate, $AgIO_3$, is $1.89 \cdot 10^{-4}$ molecules per litre. The ratio of the concentrations of the ions Cl and OH in solutions of KCl and KOH, which at the same time are saturated with AgCl and AgOH, increases by about 8 per cent, when the concentration of the alkaline salts become six times as strong, and then takes the value 0.0000. If we assume that the two argentic compounds are completely dissociated in their saturated solutions, it results from the law of mass action and from the theory of

ions that the ratio of the squares of the solubilities should be equal to the ratio of the concentrations given above, and consequently that the solubility of AgOH in water is ten times greater than that of AgCl. Now, the solubility of AgOH, determined directly by the authors as described above, is 14.4 times greater than that of AgCl determined by Kohlrausch and Rose by electrometric means. It results from this that in saturated solution AgOH is only dissociated in the proportion of 70 per cent. Finally, the authors give a process for the determination of the dissociation of the two salts dissolved in the presence of each other free from uncertain hypotheses; it consists essentially in taking as the figure for the dissociation of each salt in the mixture the figure found for the conductivity of each salt taken alone, at the same concentration, equal to the square root of the product of the concentration of its ions in the mixture.—*Zeit. Physik. Chem.*, vol. xlii., p. 336.

University College, Sheffield.—On the invitation of the Council of University College, the Fifth Chair of Chemistry has been accepted by Prof. William Palmer Wynne, D.Sc. (Lond.), F.R.S., F.I.C., Senior Honorary Secretary of the Chemical Society, in succession to Prof. Carleton Williams. Prof. Wynne is at present Professor of Chemistry in the School of Pharmacy of the Pharmaceutical Society of Great Britain. He has published some 50 papers on the Chemistry of the Naphthalene and Toluene Compounds, all in the *Journal of the Chemical Society*, of which he was the Editor for four years between 1898 and 1902. Prof. Wynne commences his new duties on September 29th next.

UNIVERSITY COLLEGE, SHEFFIELD.

The Council are about to appoint a JUNIOR DEMONSTRATOR in CHEMISTRY. Salary £120 per annum. Duties to begin September 29th next. For further particulars apply to—

W. M. GIBBONS, Registrar.

ASHTON-UNDER-LYNE SECONDARY DAY SCHOOL AND P. T. CENTRE.

The above School will be opened in the Heginbottom Technical School in October next, and the Ashton-under-Lyne Education Committee invite applications for the following Appointment:—

ASSISTANT MASTER, a Graduate in Science with special knowledge of CHEMISTRY. Commencing salary, £120.

It required to assist with Evening Work, the successful applicant will be released from Day School duties for an equivalent period of time.

The Secondary Evening Classes will re-open during September.

Applicants for the above appointment must submit full particulars as to age, education, training, and experience, with copies of not more than three recent testimonials.

Applications, endorsed "Secondary School," must be addressed to the undersigned, and must be received not later than AUGUST 1st.

D. H. WADE, Secretary of Education.

Education Office, Ashton-under-Lyne.

ABSOLUTE ALCOHOL, FREE FROM DUTY, FOR SCIENTIFIC AND RESEARCH WORK IN LABORATORIES

To be obtained from

HUGO LORENZ,
7-8, Idol Lane, Great Tower St., London, E.C.,
Licensed Trader in Alcohol and Spirits of Wine.
Stock kept in suitable packages ready for immediate use

SILICATES OF SODA AND POTASH.

IN THE STATE OF SOLUBLE GLASS OR IN CONCENTRATED SOLUTION.

Leading to Degrees and Diplomas.

The Session 1904-5 commences October 3rd, 1904.

ALL COURSES AND DEGREES ARE OPEN TO BOTH MEN AND WOMEN STUDENTS.

In the Medical School there is a separate Dissecting Room for Women, with a qualified Woman Demonstrator.

Graduates of other Universities may, after two years' study or research, take a Master's degree

SYLLABUSES with all information will be sent on application to the Secretary.

THE

DURHAM COLLEGE OF SCIENCE,
NEWCASTLE-UPON-TYNE.

Complete Courses of Instruction are provided

for Students of both sexes proceeding to the University Degrees in Science, or in Letters, and for the University Diploma in Theory and Practice of Teaching. Special facilities are offered for the study of Agriculture, Applied Chemistry, Mining, and all branches of Engineering and Naval Architecture.

Matriculation and Exhibition Examinations begin September 26th. Lectures begin October 4th, 1904.

Prospectuses on application to the SECRETARY.

UNIVERSITY OF GLASGOW.

The Medical Session will be opened on

THURSDAY, OCTOBER 13th, 1904. A Syllabus containing full particulars as to the Course of Education and as to the Preliminary Examination required to be passed by Students before beginning Medical study, may be obtained by applying to Mr. W. INNES ADDISON, Assistant Clerk.

PATENTS, DESIGNS, AND TRADE MARKS ACTS,
1883 TO 1888.

NOTICE IS HEREBY GIVEN that

EDGAR ARTHUR ASHCROFT, of The Birches, Weston (via) Runcorn, Cheshire, seeks leave to Amend the Specification of Letters Patent No. 12377 of 1903 granted to him for "Improved Process and Apparatus for the Production of Metals of the Alkali Group by Electrolysis."

Particulars of the proposed amendment were set forth in the Illustrated Official Journal (Patents) issued on July 20th, 1904.

Any person, or persons, may give Notice of Opposition to the Amendment (on Form G), at the Patent Office, 25, Southampton Buildings, London, W.C., within one calendar month from the date of the said Journal.

VOL. XC., No. 2332.

A REVISION OF THE ATOMIC WEIGHT OF BERYLLIUM.*

By CHARLES LATHROP PARSONS.

THE first determinations of the equivalent of beryllium were made by Berzelius in 1815 (*Schweigger's Journ.*, xv., 296), and consisted of a single analysis each of an undoubtedly impure hydrous sulphate and chloride, both of which were probably also basic in character. The results are therefore of no interest in a discussion of the atomic weight of this element.

In 1842, Awdejew (*Pogg. Ann.*, lvi., 106; Clarke's "Constants of Nature," p. 132) carried out an extended investigation on the sulphates of beryllium, and was the first to recognise the neutrality of the hydrous sulphate which Berzelius had considered an acid salt. He also prepared the sublimed chloride by the action of chlorine upon a heated mixture of beryllium oxide and sugar charcoal, and made three analyses of the product which did not show close agreement. They gave an atomic weight approximating 9.8, the high results being unquestionably due to the action of water on the sublimed chloride, as Awdejew dried his gas by simply passing it over calcium chloride. His work on the sulphate was of much greater value. Four results are given, varying from 9.18 to 9.49. The ratio of BeO to BaSO₄ was determined by precipitating the sulphuric acid with barium chloride, removing the excess of barium, and then precipitating the beryllium as hydroxide by ammonia. Apparently no attempt was made to weigh the sulphate itself.

Weeren, in 1854 (*Pogg. Ann.*, xcii., 124), published four determinations obtained from the hydrous sulphate by a method quite similar to that used by Awdejew, except that he precipitated his beryllium hydroxide by ammonium sulphide instead of ammonia, finding it to be somewhat soluble in the latter. His results varied from 9.18 to 9.42.

The following year, Debray published his investigation on beryllium and its compounds, and estimated the equivalent by means of the double oxalate of ammonium and beryllium (*Ann. Chim. Phys.*, [3], xlv., 37; Clarke's "Constants of Nature," p. 133). He determined the oxide by calcination after conversion into the nitrate, and also estimated the carbon in separate samples by an organic combustion. His three results are far from agreeing closely, but the ratio between the two means of BeO : 4CO₂ gave Be = 9.34.

In 1869, Klatzo (*Journ. Prakt. Chem.*, cvi., 235) obtained results varying from 9.13 to 9.40 by means of five analyses upon the hydrous sulphate, using the same method as Awdejew.

Nilson and Pettersen were the next to take up the subject, in 1880 (*Ber.*, xiii., 1451). They had for several years been engaged upon investigations of the rare earths, and had actively taken part in the controversy upon the equivalency of beryllium, which lasted so many years. In fact, they were the first chemists to definitely settle the matter by a determination of the vapour-density of beryllium chloride, and, quite contrary to their previously held opinion, to establish its bivalency. In this atomic weight work they first attempted to use the sublimed chloride, but abandoned the trial upon finding calcium in their product, and their glass tube apparently attacked. They then resorted to the crystallised sulphate, as all previous investigators, except Debray, had done, but used an entirely different method, weighing the sulphate itself after pulverising the crystals and pressing between filter-

paper, then igniting in platinum, and weighing the oxide produced. Their sulphate, too, was probably purer than any previously made, having been produced from the sublimed chloride. Their four results agreed very closely, 9.09 to 9.114.

Krüss and Moraht published their well-known investigation in 1891, their results also being obtained upon the hydrous sulphate, which they dried over phosphorus pentoxide before weighing (*Liebigs Ann. Chem.*, cclxiii., 38). Their sulphate was derived from three different sources, and was very carefully purified. They also used very much larger amounts of the sulphate for each ignition than any other investigator had done, which compelled them, however, to blast their specially constructed platinum crucible for unusually long periods of time. They made fourteen closely agreeing analyses, their results varying between 9.02 and 9.088.

All results upon the atomic weight of beryllium obtained up to the present time are therefore based upon analysis of the hydrous sulphate BeSO₄·4H₂O, with the single exception of Debray, who used the double oxalate Be(NH₄)₂(C₂O₄)₂, and may be summarised as follows:—

	Ratio determined.	Mean. O
Awdejew	BeO : BaSO ₄	9.34
Weeren	BeO : BaSO ₄	9.27
Klatzo	BeO : BaSO ₄	9.28
Debray	BeO : 4CO ₂	9.34
Nilson and Pettersen . .	BeSO ₄ ·4H ₂ O : BeO	9.104
Krüss and Moraht . . .	BeSO ₄ ·4H ₂ O : BeO	9.05

Balance and Weights.

The balance used in the analyses which follow was a new No. 1 Staudinger, which was bought especially for this work. The adjustment was so arranged that a difference in weight of 1 m.grm. caused a deflection of twenty divisions on the scale, which could easily be read to 0.2 of a division by means of the microscope attachment. The balance was placed in a second case, enclosed on all sides, and large enough to permit of convenient manipulation when the front was lifted. This case was attached directly to a brick wall two feet thick, with a shallow air space between the case and wall, and without any floor connection, so that it was not subject to any ordinary jar. It was situated in an evenly heated room. All weighings were made by the method of substitution against a tare consisting of a light thin glass weighing-bottle, containing a platinum crucible and cone of the same size and shape as those used in the analysis. This tare was treated in all respects the same as the weighing-bottles against which it was balanced, and both, on removal from the desiccator, were wiped with a soft cotton-cloth and allowed to stand in the inner balance case. This case was kept as dry as might be by means of sulphuric acid.

The weights were of brass, platinum-plated, and were compared individually and against a standard weight by the Kaiserl. Normal-Aichungs Kommission. I also compared them against each other, and my comparisons agreeing closely with those certified to by the commission, their figures were accepted as correct. All weighings were corrected to a vacuum standard.

I. Preliminary Investigations.

The Preparation of Material.—The beryllium compounds used in this investigation were derived from two sources—the first being beryl from Grafton, N.H., and the second Kahlbaum's "Berylliumhydrat."

Beryl is most readily and quickly attacked by fusion with sodium hydroxide, but no container could be procured which was not also acted upon to such an extent as to render it useless. Nickel crucibles on the market are too small to be of use except for analytical purposes, as the fused mass foams badly. The method of Lebeau (*Comptes Rendus*, cxxi., 461), who proposes the high heat of an electric furnace to volatilise a portion of the silica of the

* From the *Journal of the American Chemical Society*, xvi., No. 7.

beryl and render the residue easily decomposable by acids, has distinct advantages to those possessed of the necessary facilities. Beryl itself is not affected by any acid, even hydrofluoric, and this fact renders a separation from orthoclase and quartz, which most of the large New Hampshire beryls contain, an easy matter.

After a careful study of the many other methods for the decomposition of beryl the following procedure was adopted as the most convenient in my laboratory:—The powdered beryl was fused in a Battersea crucible with a mixture of sodium and potassium carbonates, and the fused mass turned out to cool on a smooth iron plate. The melt was pulverised and washed with water, which removed soluble sodium and potassium salts, notable amounts of silica, and some beryllium, but the loss was more than compensated for by the greater ease of the subsequent operations. The moist residue was just barely covered with water and concentrated sulphuric acid added in excess, by which procedure it became at once a dense jelly-like mass, which was easily broken up, dried, and heated on a sand-bath to render silica insoluble. The fine, nearly white and dry powder so produced was washed with hot water, potassium sulphate added to the solution, and the major part of the aluminum crystallised out as alum. The mother-liquor was oxidised with potassium chlorate and sodium carbonate carefully added in small portions at a time with intermediate boiling until the filtered solution was colourless. Most of the remaining iron and aluminum are thus precipitated before the beryllium, as Hart has pointed out (*Journ. Am. Chem. Soc.*, xvii., 604), and the selective action is undoubtedly due to the power which beryllium sulphate has of dissolving considerable amounts of its own carbonate. To the filtered solution sodium carbonate was added with care to avoid any great excess, as the precipitated basic beryllium carbonate is notably soluble in sodium carbonate solution, and the precipitate washed to remove sodium salts. It was then dissolved in excess of sulphuric acid, and the $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ crystallised out on evaporation. After a second crystallisation from pure water the sulphate was again dissolved, precipitated by ammonia, filtered, and washed, without any attempt, however, to free the gelatinous hydroxide entirely from sulphates. The removal of the main part of the ammonium sulphate is advisable, however, as the reverse reaction,—

takes place to a greater or less extent on continued boiling, after precipitating the basic carbonate from ammonium carbonate solution, and is, of course, proportional to the amount of sulphate present. The reaction may be easily complete if excess of sulphuric acid is present before neutralisation. The beryllium hydroxide was transferred to a large bottle, covered with an excess of dilute ammonia, and carbon dioxide passed through the liquid. When nearly saturated, more ammonia was added, the carbon dioxide shut off, and the bottle allowed to stand in a warm place with occasional shaking. The liquid was filtered from some undissolved aluminum hydroxide, and was treated with excess of ammonium sulphide, as recommended by Scheerer (*Journ. Prakt. Chem.*, [1], xxvii., 76) and Krüss and Moraht (*Liebigs Ann. Chem.*, cckxii., 47). A small amount of a black precipitate was invariably thrown down at this stage. After standing for several days, the solution was filtered, with special care that the black precipitate was at all times in contact with liquid containing ammonium sulphide. It was then boiled with constant stirring until ammonia was evolved and precipitation was complete. Vigorous stirring of some form is absolutely necessary as the granular precipitate settles quickly, and causes violent bumping, which I have never been able to prevent by any other method. The basic carbonate thrown varies continually in composition as precipitation progresses, but the final product has the approximate formula $\text{Be}[\text{Be}(\text{OH})_2]_2\text{CO}_3 \cdot 2\text{H}_2\text{O}$ when dried over sulphuric acid.

It is slightly soluble in water, so precipitation is never quite complete. At 100° it loses about 4.50 per cent of water, and contains about 44 per cent of BeO . Like all the basic compounds of beryllium which have come under my observation, except those of the acetate group to be described later, its composition is by no means definite. The carbonate was twice re-dissolved in pure sulphuric acid, and re-precipitated from ammonium carbonate as described above, except that the treatment with ammonium sulphide, although each time repeated, failed to separate any further black sulphide.

Kahlbaum's "Berylliumhydrat" contained quite notable amounts of aluminum and small quantities of iron. It was precipitated three times as basic carbonate, exactly as described above, and the small amount of dissolved iron thrown out by ammonium sulphide.

The basic carbonates so prepared were employed as a basis for the production of the purer salts used in the atomic weight determinations. They contained small amounts of aluminum, but were free from other admixture.

The Ammonium Sulphide Precipitate.—Krüss and Moraht lay special stress upon the removal of the black precipitate formed by adding ammonium sulphide to the ammonium carbonate solution, and attribute the fact of their low results to its removal. In fact, their investigation was undertaken with this idea in view. According to them the precipitate was not due to iron, but, while yielding a black sulphide, gave a white hydroxide (*Liebigs Ann. Chem.*, cckxii., 47). They promised further investigation. Apparently unknown to them Scheerer had, on July 15, 1842 (*Journ. Prakt. Chem.*, [1], xxvii., 76; *Pogg. Ann.*, September, 1842), read a paper at Stockholm in which he recommended the same procedure for the removal of the small amount of iron dissolved in the ammonium carbonate, and Vauquelin, in one of his early articles (*Allg. Journ. dt. Chem.*, i., 595), speaks of the difficulty of removing the last traces of iron, but says it can be done by means of potassium hydrosulphide. This must have been done in ammonium carbonate solution.

The matter has been one of interest to chemists working on beryllium and its compounds since the article of Krüss and Moraht was written, for it appeared to follow that, if their statement of a black sulphide and white hydroxide was true, a new element was under consideration. As the amount of precipitate is small, I began some three years ago, in the early part of my work on beryllium, and while working on beryl, to save the small amounts of black precipitate obtained with each new lot of material. Fortunately, I did not realise for some time the desirability of removing the ammonium sulphate previous to solution in ammonium carbonate, so that the filtering of the ammoniacal solution after precipitation of the hydroxide was omitted. In this way about a gram. of the black precipitate was collected, and on analysis it proved to be a mixture of the sulphides of iron and zinc, but mainly zinc. On adding ammonia, with care to avoid excess, it yielded a precipitate which, in small amounts, might easily have been called white, while on addition of ammonium sulphide the black iron sulphide immediately predominated. Over 0.5 gram. of zinc oxide was separated in the pure state, and was procured from several kilograms. of beryl. I believe the presence of zinc in beryl has not before been noted.

The "Berylliumhydrat" was also carefully examined, and the presence of zinc established, but in very small amounts. It is quite probable that this material had been washed from alkaline solution, which would, of course, have removed the greater part of the zinc.

Beryllium Chloride.—It is quite generally conceded that atomic weight determinations based upon the analysis of the metallic halides, are among the most accurate made, and it is highly desirable that the beryllium equivalent be determined on the pure chloride. Unfortunately, however, it has properties which render the task extremely difficult, being immediately acted upon by the slightest trace of water, and according to Nilson and Pettersen (*Ann. Chim. Phys.*, [5], xiv., 428), and Humpedge (*Proc. Roy. Soc.*,

xxxix., 1) it attacks glass. In my earlier studies on the subject I had hoped to be able to purify the chloride by the same method that Richards used for magnesium (*Zeit. Anorg. Chem.*, xiii., 92), by evaporating carefully a mixture of the chlorides of beryllium and ammonium in a perfectly dry current of hydrochloric acid gas, and subliming off the ammonium chloride. Early experiments showed that the ammonium chloride did prevent the decomposition of the beryllium chloride, and a dry mixture but little, if any, decomposed could be obtained. On heating, however, they both sublimed together, and no separation could be made, in spite of the fact that Carnelley places the melting-point of beryllium chloride as between 858° and 890° (*Phil. Mag.*, [5], xviii., 21). If the mixture be dried and heated in air, the ammonium chloride alone sublimes, leaving the oxide of beryllium in so light and feathery a form that it is carried by air currents about the room.

The normal chloride, bromide, and iodide were first made by Wöhler by heating a mixture of the oxide and carbon in the appropriate gas, and subliming the product (*Ann. der Phys.*, xliii., 577). The chloride was also made from the metal itself by sublimation in dry hydrochloric acid gas by Nilson and Pettersen. Lebeau has recently prepared the iodide from the carbide in a similar manner (*Comptes Rendus*, cxcvi., 1272). The chloride and iodide have quite similar properties. The bromide has been little studied. All are attacked violently by water with evolution of the corresponding acid. The solution of the chloride is strongly acid in reaction, readily dissolves the carbonate or loses hydrochloric acid on evaporation. Evaporation on the water-bath or *in vacuo* by sulphuric acid has, in my hands, invariably yielded basic compounds. I have made many analyses of these basic chlorides, but no two products have ever agreed in composition, nor has crystalline structure ever been observed. Heating to a high temperature yields the pure oxide, but a small amount of BeCl_2 seems to be always sublimed after the last traces of water have been driven off. Every attempt to make the compound $\text{BeCl}_2 \cdot 4\text{H}_2\text{O}$, described by Awdejew, met with failure. No crystalline chloride of any degree of hydration could be prepared. I believe the existence of this compound to be highly improbable. Some recent experiments have led me to seriously doubt the conclusion of Nilson and Pettersen, and Humpedge, as to the action of BeCl_2 on glass, at least upon Jena or hard potash glass, in both of which I have sublimed the chloride from place to place, and repeatedly from the same place, without the slightest sign of action so long as all moisture was absent. The least moisture, however, caused a thin film of the oxide to form, which might easily be mistaken for corrosion, and which adhered tenaciously to the glass.

Beryllium Sulphate.—Beryllium forms two normal sulphates, $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ and $\text{BeSO}_4 \cdot 2\text{H}_2\text{O}$, which are definite in composition under proper equilibrium conditions. As will be shown in another paper soon to be published, the sulphate $\text{BeSO}_4 \cdot 7\text{H}_2\text{O}$, described by Klatzo (*Journ. Prakt. Chem.*, cvi., 233), does not exist, and it is doubtful if the anhydrous sulphate BeSO_4 has ever been prepared pure. It is upon the tetrahydrate that the accepted atomic weight of beryllium rests. The dehydrated salt is produced from the tetrahydrate by heating at 100° , and is apparently stable in dry air below this temperature. It was an intermediate step in the work of both Nilson and Pettersen and Krüss and Moraht, and would have given a second ratio for the determination of the equivalent.

In the early stages of my work on the sulphate it became apparent that I could not dry the normal tetrahydrous salt over phosphorus pentoxide as Krüss and Moraht had done, for the material slowly but continuously lost in weight. No absolutely definite point could be taken as representing exactly the salt $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$, although the powdered crystals are stable at ordinary temperatures and pressures when air-dried. Under these conditions they probably are as near to the accepted formula as is the case with most hydrous salts. Nilson and Pettersen seem to have recognised this fact, for they made no attempt to dry their

air-dry material other than by pressing between filter paper. To establish more definitely the instability of the water of crystallisation I undertook a series of tensimeter experiments. With phosphorus pentoxide as the desiccating agent, the water of crystallisation of the tetrahydrous salt shows a pressure of 20 m.m. olive oil at 20° , and this pressure increases rapidly as the temperature of the thermostat rises. The pressure in the tensimeter was many times equalised and the experiment repeated. Weeren (*Ann. der Phys.*, xcii., 124) states that $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ loses one-third of its water at 35° . The dihydrous salt $\text{BeSO}_4 \cdot 2\text{H}_2\text{O}$, while for all ordinary purposes stable at 100° , appears to very slowly lose its water of crystallisation if continuously maintained at this temperature. I have never been able to obtain the same equivalent from the weight of $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ taken and the weight of $\text{BeSO}_4 \cdot 2\text{H}_2\text{O}$ derived therefrom. One would naturally suppose, since Krüss and Moraht first dried their salt to slowly remove the first 2 molecules of water before ignition, that they arrived at a like conclusion. This fact in itself should, in the absence of other proof of definiteness of composition, render the use of either for atomic weight purposes subject to question.

In order to repeat the work of previous investigators on the sulphate, I prepared a quantity of a very pure salt by first dissolving the carbonate, already mentioned, in hydrochloric acid and treating according to the method of Havens (*Zeit. Anorg. Chem.*, xv., 18) to remove any aluminum remaining. During the course of this work it was discovered that if the filtered saturated solution of beryllium chloride in the ether hydrochloric acid mixture was cooled down or supersaturated, a mass of beautiful white needle-like crystals were formed, which could be separated from the mother-liquor by means of a Buchner funnel without the use of filter-paper. These crystals contain all the constituents of the solution—beryllium chloride, hydrochloric acid, ether, and water. Their exact composition is yet to be determined, but as they seemed to offer a further means of purification, all of the beryllium chloride used in the preparation of the sulphate was passed through this medium. On exposure to air the crystals were decomposed, losing ether and hydrochloric acid. The purified material was dissolved in excess of ammonium carbonate, boiled, precipitated, and washed free from chlorides and ammonia. The carbonate so produced was dissolved in slight excess of carefully purified sulphuric acid. On evaporation, crystals of $\text{BeSO}_4 \cdot 4\text{H}_2\text{O}$ were obtained, which were four times crystallised from water, washing each time with absolute alcohol. The crystals so prepared were dissolved in pure water, evaporated to the crystallising point, and the viscous hot solution poured into a large excess of strong alcohol. No precipitation occurred at once, although a milky, apparently colloidal, solution was produced, which, on standing over night, crystallised out almost completely. This was repeated once, and the crystals so obtained were dissolved in carefully purified water, evaporated, and crystallised as small crystals by stirring. When air-dry they were powdered and used for determination of the equivalent and for the experiments already briefly described. Determinations were made on both the air-dried sulphate and upon sulphate which had been, for a short time only, over phosphorus pentoxide. The sulphate was weighed into platinum crucibles, dried at 100° , re-weighed, and dried at a gradually increasing temperature in a Jannasch beaker until the remainder of the water and most of the sulphur trioxide was removed. It was then blasted to complete removal of the sulphur trioxide. This required a very high temperature and was not complete, with the blast at my command, if the platinum crucible was protected by enclosure in a second. Fortunately, however, the oxide produced from the sulphate did not in the least adhere to the platinum crucible. The final weight of the crucible was, therefore, taken in determining the weight of the oxide. Nilson and Pettersen, and Krüss and Moraht both blasted platinum direct and mention no correction therefor. It would seem likely, however, that Krüss and Moraht made such a correction, for they speak of having to

diminish the weight of the platinum crucible used as a tare in order to balance the one used in analysis. They used such large amounts of material that this error would be comparatively small in their results.

It has not been deemed necessary to enter into details of manipulation, but full precautions were observed, as described in the analyses to follow. Results on the sulphate yielded atomic weights from 9.18 to 9.36. Sources of probable error were so apparent that I had no confidence in the results obtained, and they will not be included in the final summary. The work is described for its bearing on the investigations of others, and to call attention again to the probable errors in using a hydrous salt as a basis for the determination of atomic weight. Unfortunately, until quite recently, no other salt seemed to be available in the case of beryllium.

(To be continued).

NOTE ON THE URINE OF A TORTOISE.

By L. DE KONINGH.

THIS very clear specimen had a faintly acid reaction. Total solids, 1.03; ash (nitrated), 0.63 per cent. On heating the residue, a slightly aromatic, but not at all offensive odour, was noticed. The ash was slightly phosphatic. The urine gave no precipitate with picric acid, but a strong darkening on applying the bismuth test for sugar; the usual precipitate was not noticed.

After being kept in a test-tube for two days the sides were coated with a transparent crystalline deposit, which was found to be insoluble in strong acetic acid, but which gave the murexide reaction.

The liquid poured off from the deposit was tested in a nitrometer with excess of alkaline bromine solution. 1.4 c.c. of the urine yielded only 0.2 c.c. of gas.

THE IODOMETRIC ESTIMATION OF IRON IN THE FERRIC STATE.

By R. NAMIAS AND L. CARCANO.

THE volumetric estimation of iron is almost always carried out in solutions in which the iron is in the ferric state. With the ordinary permanganate method it is important to have only sulphuric acid present, because under all conditions hydrochloric acid has an action on the permanganate that cannot be overlooked; it is difficult to observe the end of the reaction accurately, since the colour obtained, after having oxidised the whole of the ferrous salt, disappears rapidly. With a view to avoiding the long operation necessary for the elimination of the hydrochloric acid, we can make use of Penny's method, in which we use a titrated solution of bichromate, and the touch method with a solution of ferricyanide of potassium, to find the exact moment at which the blue colour of the ferrous ferricyanide ceases to be formed. The method devised by Namias (*Moniteur Scientifique*, Feb., 1900) is much preferable, but it is little known although it is very exact.

This method is founded on the estimation of the ferrous salt in neutral solution (containing pure oxide of zinc in suspension) by permanganate of potassium. Under these conditions the reaction does not take place, as in acid solutions, between 10 atoms of iron in the ferrous state and 2 molecules of permanganate, because in this case the reduction of the permanganate stops after the formation of the MnO_2 . This method depends on the following simplified reaction:—

As will be easily understood, this method enables us to neglect entirely the nature of the acid combined with the iron, provided we have not to do with a reducing organic

acid. The operation should be carried out warm so as to deposit the oxides and to observe when the liquor commences to turn red. One of the most persistent drawbacks of all the methods in which the iron is estimated volumetrically in the ferrous state, is the necessity for reducing the ferric salt to the ferrous state. With this operation, besides losing a great deal of time, we have the further drawback that the impurities contained in the zinc, especially the small quantities of iron, may cause an error which is often important and never negligible, as we have proved.

We have not found any zinc, supplied as very pure, which after solution will not reduce a little permanganate; it is necessary, therefore, to calculate with the greatest accuracy the amount of permanganate reduced by a known weight of the zinc. The utility of a method which will enable us to estimate the iron in the ferric state directly, and by volumetric means, is evident, especially when we are dealing with the analysis of lime, slags, iron ores, refractory materials, &c.

We can safely say that up to the present there is no method known by which iron can be determined volumetrically and accurately in the ferric state.

The method based on the use of stannous chloride is very inconvenient, and not to be depended upon, because of the rapid variation of the strength of the solution of stannous chloride, even when kept in special apparatus.

The method founded on the reduction of the ferric salt by hyposulphite of sodium in the presence of a salt of copper, is inaccurate also, as was recognised by Fresenius, and it requires very careful manipulation.

The only method which is very simple and rapid in practice, and looked upon as exact, is the one founded on the following reaction:—(1) $Fe_2Cl_6 + 2KI = 2FeCl_3 + 2KCl + I_2$.

This method, examined by Mohr and Braun, is considered by Fresenius to be practically accurate. We have followed the instructions of Fresenius closely, and we have also endeavoured to modify them as far as time, the dilution of the liquid, and acidity is concerned, but in no case have we obtained accurate or even approximate results. This can be seen in the table of results we give at the end of this article.

We are convinced that the principal reason for the inaccuracy of the method must be attributed to the great facility with which the inverse reaction takes place, that is to say:—(2) $2FeCl_3 + 2HCl + I_2 = Fe_2Cl_6 + 2HI$.

Thus, it is evident that if we could remove a great part of the iodine set free, the reaction would take place quantitatively. We first of all tried to get rid of the greater portion of the iodine by heating the solution to boiling in a current of carbonic acid, and collecting the iodine in a solution of iodide of potassium, and estimating both the iodine given off and that remaining. The results approach the truth closely, but they are too low.

We next endeavoured to remove the greater part of the iodine by means of a small quantity of chloroform added to the solution, and this is the method that gave us the best results. These results are very accurate and are such that no other method for the volumetric determination of iron can surpass.

The following is briefly our method of proceeding:—

The solution containing the salt of iron, oxidised with nitric acid, is evaporated to dryness with an excess of hydrochloric acid; the residue is dissolved in the smallest possible quantity of hydrochloric acid. The solution is diluted with water until it contains about 1 or 2 per cent of iron.

The solution is almost completely neutralised with carbonate of soda, add concentrated hydrochloric acid until about 5 to 10 per cent of acid is present, then add 5 or 10 c.c. of pure chloroform. Leave for several hours, twelve if possible, in a closed matras, shaking occasionally. The iodine set free is estimated with a titrated solution of hyposulphite of sodium in the presence of starch emulsion.

It is necessary to make a blank experiment with the same quantity of chloroform and iodide of potassium dissolved

in a small quantity of water, and treated with the same amount of hydrochloric acid as is used in the actual analysis. In this manner we find that a small quantity of iodine is always set free under these conditions; naturally this iodine should be subtracted from the total iodine. We have attempted to apply an analogous method to the estimation of copper in the state of cupric chloride, and we have obtained satisfactory results. We shall make further experiments with a view to finding the best conditions for applying the method to this case.

Solution of Ferric Chloride containing 1 per cent. of Iron, slightly Acid.

	Fe per cent.
10 c.c. with 24 grms. of iodide of potassium: left for twelve hours in the cold ..	81.00
Heated in a matras, containing a solution of iodide of potassium, and titrated immediately ..	75.00
Ditto ditto, after standing two hours ..	74.00
With the addition of acetate of soda in the cold	69.06
Distillation of the greater portion of the iodine in a current of carbonic acid ..	93.08
Acidulated with a drop of concentrated hydrochloric acid, treated with chloroform, and left for twelve hours in the cold ..	98.52
With 1 c.c. of hydrochloric acid, and left for twelve hours ..	99.6
The same repeated ..	99.6
Repeated, but without standing ..	90.0
Add 1 c.c. of hydrochloric acid, left for nineteen hours ..	99.3

The iron used for these estimations was pianoforte wire, which might contain 0.3 to 0.4 per cent. of impurities (C and Mn).—*Moniteur Scientifique*, vol. xviii., April, 1904.

CONSTITUTION OF NITRIC PEROXIDE.

By EDWARD DIVERS, M.D., D.Sc., F.R.S.,
Emeritus Professor of Chemistry, Imperial University of Tokyo.

In a paper appearing in the *Journal of the College of Science, Imperial University, Tokyo* (vol. xix., Article 15), Haga has demonstrated that Fremy's sulphazilate is an oximeperoxide and a tervalent nitrogen compound. If Hantzsch and Semple's suggestion is accepted (*Ber.*, 1895, xxviii., 2744; cf. Piloty and Schwerin, *Ber.*, 1901, xxxiv., 1884 and 2354), that Fremy's salt is also a sulphonated nitric peroxide, it follows that the constitution of nitric peroxide is at last determined, being that of nitrosyl peroxide. Hantzsch and Semple must be right, for, after Haga's researches, a sulphazilate as a peroxylaminesulphonate cannot be supposed to be other than a sulphonated nitric peroxide. It only remains, therefore, to show that nitric peroxide is a true peroxide in its chemical relations.

It is formed from nitric oxide and oxygen, just as sodium peroxide is formed from sodium and oxygen. Nitrous acid cannot, indeed, be shown to pass simply into it and back again, as a hydroxylaminedisulphonate (sulphonated nitrous acid) changes into a peroxylaminesulphonate, but that is only on account of its own instability and that of nitrous acid.

Its interaction with organic oximes, in which it converts these substances into peroxides and becomes hydrogenised into nitrous acid (Scholl), is in accordance with its nature as a true peroxide. Similarly, it converts a hydroxylaminedisulphonate into a peroxylaminesulphonate (Haga).

Nitrosyl peroxide and a peroxylaminesulphonate both interact with water in essentially the same way, the apparent difference being due to the limits imposed by the sulphonation in the case of the latter substance. The former yields half its nitrogen as nitric acid and half as nitrous acid, whilst the latter yields half its nitrogen as a mixed anhydrosulphate (hydroxylaminetrisulphonate) and

the other half as nitrous acid and sulphonated nitrous acid (hydroxylaminedisulphonate):—

It would seem, therefore, that wholly on the evidence afforded by Haga's work, it can now be confidently asserted that dinitric peroxide is nitrosyl peroxide and a compound of exclusively tervalent nitrogen. The constitution of mononitric peroxide, in regard to these two points, remains to be considered, but can hardly be very different.

Hantzsch and Semple have suggested (*loc. cit.*) that the bluish-violet dissolved form of a peroxylaminesulphonate corresponds with mononitric peroxide, and its crystalline form with dinitric peroxide. Since then, Piloty and Schwerin (*loc. cit.*) have expressed the belief that porphyrexide, which has the colour of mononitric peroxide, may also be a derivative of this peroxide, because it contains the group :NO singly, as shown by the formula $(\text{C}_5\text{H}_5\text{N}_3):\text{NO}$. Its molecular weight, however, has been only indirectly ascertained, that is, by cryoscopic determinations of those of its nitrate and its chloroderivatives. That its molecular weight is not double as great is a remarkable fact, for, in its chemical behaviour, and especially in its reversible relation with porphyrexine $(\text{C}_5\text{H}_5\text{N}_3):\text{NOH}$, porphyrexide seems to belong to the class of oximeperoxides. Piloty and Schwerin do not indeed recognise this, and have instead come to the conclusion that the nitrogen of the group :NO in porphyrexide and in mononitric peroxide must be quadrivalent. In the light of Haga's experimental results, this view of the matter has become untenable, since porphyrexide and the peroxylaminesulphonates appear to belong to the same class of nitroso compounds, as Piloty and Schwerin themselves have pointed out.

In the few cases in which it has been possible to determine cryoscopically the molecular weight of a glyoximeperoxide, this has been found to include :NO twice. This result may be owing to the glyoxime constitution of these peroxides, but even so there is still no peroxide, except mononitric peroxide, and possibly porphyrexide, the molecular weight of which is such that it contains the group :NO only once. The occurrence of many nitroso-compounds in a colourless, solid form, and in a bluish-violet liquid form, does not lend much assistance in deciding the molecular weights of the two forms of a peroxylaminesulphonate, since they contain not :NO but :NO. But it must not be left out of sight that Piloty (who thinks otherwise, and has been followed by Schmidt, Bamberger, and others) has succeeded in showing that the white form of these compounds contains the group :NO twice, and that the deeply-coloured modification contains it only once. But here the latter is the form which must be treated as the chemically active one, whilst the double weight found for the white form has to be left uninterpreted chemically, as, for example, in the case of the formula $(\text{C}_5\text{H}_7\text{NO})_2$ for nitroso-octane.

In the paper by Hantzsch and Semple (*loc. cit.*) there occurs, but in a footnote only and without comment or explanation, the punctuated formula $\text{O}:\text{N}:(\text{SO}_3\text{K})_2$; whether this is to be regarded as a printer's error for $\text{O}:\text{N}:(\text{SO}_3\text{K})_2$ is uncertain, but if it is not it indicates some recognition by these chemists of the presence of univalent oxygen. However this may be, the possibility of the nitrogen being quadrivalent being inadmissible, the only solution of the matter seems to be to consider that both mononitric peroxide and porphyrexide are compounds of univalent oxygen, although still peroxides. The fact that a molecular quantity, such as that formulated by $\text{HO} \cdot \text{NO}_2$, $(\text{SO}_3\text{K})_2\text{NO}$, or $(\text{C}_5\text{H}_5\text{N}_3)\text{NO}$, is never met with singly in chemical interactions militates against the acceptance of this explanation. Piloty and Schwerin, in discussing the quadrivalency of nitrogen, conceal this fact by stating that porphyrexide is produced from porphy-

rexine by the action of *half an atom* of oxygen. It is much more correct to hold with Haga that the molecule of peroxylaminesulphonate, and therefore also of mononitric peroxide and of porphyrine, is not less than that represented by $[\text{NO}(\text{SO}_3\text{K})_2]_2$, $(\text{NO})_2$, or $(\text{C}_5\text{H}_7\text{N}_2\text{O})_2$. as the case may be, if by molecule is meant the smallest chemically active weight of a substance. But still the fact remains that, when measured by comparison of their physical properties, the molecular weights of porphyrine and red nitric peroxide are expressed by half the above formulae, and probably the bluish-violet form of a peroxylaminesulphonate has also a molecular weight, which when physically considered, should be expressed by the formula $\text{NO}(\text{SO}_3\text{K})_2$. These weights, only physically determined, have no chemical significance, and should be distinguished from their doubles, the truly chemical molecular weights. But, as pseudochemical molecules, they must be represented to contain a univalent atom of oxygen.

It is, after all, not so difficult to admit that oxygen may be univalent in a peroxide. In fact, true peroxide may be defined and differentiated from other oxides, as being a compound in which some or all of the oxygen is exerting on the rest of the compound only half its usual valency. Or, conversely, a peroxide may be defined as a compound containing oxygen which is either actually univalent or exteriorly and quasi-univalent. Apart from the unfamiliar nature of the conception of actually univalent oxygen, it seems natural enough to find a normal molecule of nitric peroxide dissociate at a gentle heat into two identical but simpler ones, in consequence of the linked oxygen atoms becoming parted and losing valency. On the other hand, the assumption that nitrogen is quadrivalent does not accord with the result actually obtained, when by cooling nitric peroxide it is found that the valency of the nitrogen decreases instead of increasing, 2O:N:O becoming O:N:O:N:O .—*Journ. College of Science, Imperial University, Tokyo, xix., Art. 17.*

THE ATOMIC WEIGHT OF TUNGSTEN.*

By EDGAR F. SMITH and FRANZ F. EXNER.

(Concluded from p. 52).

Preparation of Tungsten Hexachloride.

CHLORINE, free from oxygen and moisture, is absolutely essential to obtain this compound pure and in comparatively large amounts. The product must also be sublimed repeatedly in an atmosphere of chlorine, without exposure to the air. The first condition, although apparently simple, is really very difficult to attain; and after much experimenting, we cannot say that we got chlorine absolutely free from moisture. But the quantity of oxychloride formed along with the hexachloride may be taken as an index of the amount of moisture (also oxygen) in the chlorine.

The generator was charged with material sufficient to yield chlorine an entire day without the addition of acid, and consequent introduction of air into the apparatus. When the flow of gas commenced to grow less only the gentlest heat was applied for a few minutes to the generator. The chlorine was most completely dried by conducting it through three six-inch U-tubes, connected in series, containing pumice stone saturated with pure concentrated sulphuric acid, and in the bend sufficient acid to fill the bottom of the tubes, thus causing the gas to bubble through the acid before each new preparation. Indeed, it was about every fourth day that a renewal was made. Only traces of oxychloride were observed. The reaction of chlorine and metal took place in a combustion tube of soft glass, 15 to 18 m.m. in diameter and 4½ feet in length. The tube was contracted in two places to the thickness of a lead pencil, thus making three sections, of which the first was 3 feet in length, the second 1 foot, and the last ½ foot. A porcelain

boat carried the tungsten metal. The chlorine was passed through the apparatus for two hours before any heat was applied. This was done to expel the air. Then the burners of the furnace (to within three of the boat) were lighted, beginning with those most distant from the boat, the flames being small. The tube beyond the boat thus reached a temperature of nearly 350° C. These burners were then extinguished, while those immediately beneath the boat were lighted, the flames being small. The tube to a length of eight inches beyond the boat was also heated. In a very short time the reaction began, noticeable at first in the yellow vapours which condensed in the colder part of the tube, beyond the furnace, to the light brown oxychloride. This did not continue more than two minutes, when copious reddish brown vapours appeared, and condensed beyond the lighted burners to brilliant blue-black needles. The formation is very rapid. The utmost vigilance is constantly required to the very conclusion of the experiment. In two hours 20 grms. of metal may be fully converted into hexachloride. That portion of the combustion tube at which the hexachloride condenses should be kept just hot enough to cause the traces of oxychloride to pass beyond the hexachloride. This can be readily adjusted after a little experience. When working with large amounts the deposits of the hexachloride may obstruct the tube. In that event manipulate a lamp-flame with the hand beneath the chloride until it is partially melted. This converts it into a compact solid, requiring less space. Melting and re-sublimation of the chloride removes every trace of oxychloride. Two sublimations are sufficient for the purpose. The tube can then be sealed off at the contracted points. Perfectly pure hexachloride has a beautiful brilliant steel-blue colour. It can be readily transferred to clean dry weighing bottles, and preserved in them. It has marked stability. There is no perceptible action on bringing the chloride into water at the ordinary temperature, even after considerable time. On the application of heat the decomposition does not begin until the temperature of the water reaches 60°. The specific gravity of the hexachloride, taken in water at the ordinary temperature, equalled 3.518. After all the weighings were made the water employed for the purpose was tested with litmus; it gave the very faintest acid reaction. Having obtained in the above manner large quantities of the hexachloride, it was decided to change it to trioxide, and thus arrive at the atomic weight of the metal. Roscoe had determined the chlorine in this compound. His results were not especially concordant. Perhaps this was due to the involved method or to the presence of traces of oxychloride. However, our thought was to adopt the simplest available course, hence we aimed to convert the chloride into oxide. Roscoe has stated that when hexachloride is directly decomposed with water and the resulting acid ignited to oxide, the latter will contain chlorine which cannot be expelled by heat. We had hoped to pursue this method, but as it had the condemnation of so high an authority the hexachloride was introduced into freshly distilled ammonia water, contained in a weighed platinum dish, with the expectation of eventually getting ammonium tungstate and chloride which would leave the trioxide upon ignition. Experience showed that the quantity of the resulting ammonium chloride was so great that even with the most careful ignition there was much danger of expelling mechanically appreciable amounts of the oxide. Nor was it forgotten that it is very doubtful whether from such a mixture the chlorine could be completely removed by heat.

The treatment of the hexachloride directly with nitric acid was also found impracticable.

In spite of Roscoe's objection to the decomposition with water, it was believed that the transposition could be carried out. Five glazed No. 2 porcelain crucibles of 40 c.c. capacity were selected, thoroughly cleansed and ignited, allowed to cool in vacuum desiccators, and weighed upon a specially constructed Troemner balance, sensitive to one-tentieth of a milligram. There was next introduced into

* From Proceedings of the American Philosophical Society, vol. xliiii., No. 176.

each one of them tungsten hexachloride from a weighing bottle, which was re-weighed after the removal of each portion. The crucibles with their chloride content were placed on water-baths, and cold distilled water introduced into each. When the volume of water was insufficient for the quantity of chloride, sufficient heat was generated by the reaction to make the water boil, and spattering followed. At 60° the decomposition proceeded quietly to the hydrated trioxide, which at the beginning had a slight greenish yellow colour, due probably to imperfect decomposition, as mentioned by Roscoe, but this tint disappeared as the hydrochloric acid was expelled. When the mass was perfectly dry a few drops of pure concentrated nitric acid was introduced from a pipette upon the trioxide. Instantly any green tint vanished, and was replaced by a rich orange-yellow colour. The excess of nitric acid was slowly evaporated away, and the oxide assumed a pale yellow hue.

The crucibles were now removed from the water-bath, and after careful drying were ignited for half-an-hour to a dull red heat, then allowed to cool in the desiccator, and at the expiration of an hour and a-half were weighed.

In the calculations the values for oxygen and chlorine were taken at 16 and 35.45 respectively. The specific gravity of tungsten trioxide was found to be 7.157, and that of tungsten hexachloride 3.518.

Seven different series of determinations were made, each from a different sample of hexachloride. The results appear in the subjoined table:—

No. of expt. series.	No. of of	Weight of WCl ₆ corrected for vacuum. Grms.	Weight of WO ₃ corrected for vacuum. Grms.	Atomic weight of W.	Means of series.	Mean of means.

27.		7.37889	4.31643	184.14		

It should be mentioned here that at the conclusion of these experiments etching or corrosion of the glaze of the crucibles could not be observed. Nor was there any stain upon them; they looked as if they had been unused.

Metallic Tungsten.

It would be superfluous to set forth here the steps taken in procuring the metal. They are familiar to every reader. They were identical with those described by Hardin. One point, however, is worthy of notice. It was discovered that if the trioxide, reduced to metal, had been previously gotten by the ignition of ammonium paratungstate in vessels of platinum, then it might well be expected that

after the removal of the tungsten from the reduction boats the latter would show dark spots here and there. This occurred, but uncontaminated trioxide was repeatedly reduced in porcelain by hydrogen without leaving dark stains.

Several experimenters—Riche, Desi, Shinn, and Hardin—endeavoured to reach the atomic value of tungsten by collecting the water resulting from the reduction of definite amounts of trioxide in hydrogen. Their results were disappointing in the extreme, although the method is surely rational and in some measure ideal. The reasons for its failure have never been satisfactorily explained. We were induced to give it trial. Every attention to detail was scrupulously observed. The results were most disappointing, and yet we cannot give a reasonable explanation for our failure. There seems to be an inherent defect in the method which we were unable to lay bare.

We also reduced definite quantities of trioxide to metal, and from the loss in weight sought to get the atomic value of tungsten. Again the results were discordant. The boats were never stained from the reduction, nor was the porcelain tube in which the reduction took place stained, but on close scrutiny particles of metal could be seen along the sides of the tube. They rested loosely upon it, and were removed with ease. This metal, in all probability, was carried out into the tube by the aqueous vapour produced in the reduction. This is therefore a serious point in this method.

There remained, finally, only Method 2, another time-honoured method, upon which much discredit had been cast. Yet with pure material it seemed worth the while to give it further trial. The metal used in this study was made from trioxide obtained from the hexachloride. Portions of it were weighed out into the same crucibles which had been used in the experiments with the hexachloride and gently heated with air contact. The steps in the ignition were those which any careful analyst would observe, so that they need not be mentioned here. The final oxide was uniformly yellow in colour throughout its entire mass.

The weighings here, as in all previous experiments, were reduced to vacuum standard. The value of oxygen was placed at 16. The specific gravity of the oxide was, as before, 7.157, and that of the metal—19.

In the appended table it is to be understood that each single series was made from portions of the same sample of metal. The results are:—

No. of expt. series.	No. of of series.	Weight of W. Grms.	Weight of WO ₃ Grms.	Atomic weight of W.	Means of series.	Mean of means.
1.	I.	2.24552	2.83144	183.96	183.96	
2.	II.	1.78151	2.24619	184.07	184.07

23.		4.96735	6.26229	184.13		

In Series VII., a very large quantity of oxide was heated in hydrogen from 9 a.m. until 5 p.m. The resulting metal was placed over night in a desiccator, and on the following day a portion of it was weighed out for the eighteenth experiment, the remainder being heated for a day more in hydrogen. After standing over night a second portion was removed and used in Experiment 19. The remainder was exposed all of the third day to the action of hydrogen, and was then oxidised for Experiment 20. Had not the first reduction been complete, the results would not have agreed so well.

The mean atomic value from the hexachloride is 184.04, that from the oxidation of metal 184.065, or the average of the two independent series is 184.05, which probably approximates the truth very closely, and may be safely regarded as the atomic weight of tungsten.

Summary.

Our study, extended over so long a period, has revealed:—

1. That it is quite doubtful whether any chemists who in the past occupied themselves with a determination of the atomic weight of tungsten have worked with pure substance. Tungstic acid is prone to form "complexes." It was found that if the acid contain no iron, for instance, but be digested with acids, e.g., hydrochloric or nitric acid, in which iron is present, the latter will enter the tungstic acid. Iron and manganese are eliminated from the acid with the greatest difficulty. In the earlier work there is no evidence of their removal. Neither do we discover that vanadium and phosphorus had been considered as present, yet in purifying ammonium paratungstate by re-crystallisation alone it was found that the tenth re-crystallisation showed vanadium.

2. The slimy greenish or bluish white masses, believed to be "paratungstates" because of their great insolubility, are probably "complexes."

3. The fourth method of purification can be relied upon to yield pure tungstic acid.

4. The use of pure sodium carbonate (2 per cent) to dissolve tungsten trioxide gives an excellent means of ascertaining when the iron, manganese, and silica are fully removed, but that its development into a method for the determination of the atomic weight of tungsten is not at all probable.

5. The plan of digesting pure ammonium paratungstate with nitric acid, then evaporating to complete dryness and gently igniting, affords pure oxide.

6. That porcelain vessels are preferable to those of gold, silver, or platinum for the ignition of ammonium paratungstate and tungstic acid.

7. That the oxidation of metal (Method 2) leads to reliable atomic numbers when the material is pure.

8. That tungsten hexachloride can be completely transposed into pure oxide with water and a little nitric acid.

considering it to be gum. Professor Wiesner (Abstract, *Pharmaceutical Journal*, 1871, Series 3, vol. ii.) stated that it was closely allied to Acacia gum, and J. H. Maiden (*Proc. Linn. Soc. N.S.W.*, 1899 and 1891) later formed one of his *Eucalyptus* kino groups (the Gummy Group) upon its presence. It does not appear possible to obtain it in a crystallised condition, nor could it be removed from aqueous solution by miscible solvents. It was obtained in as pure a condition as possible by repeated precipitation by alcohol from concentrated aqueous solutions. When dried and powdered, it was of a cinnamon colour, and this colour was not removed by boiling with animal charcoal. It is very soluble in water, and when boiled with acid for some time a "kino red" is formed in quantity, a sugar being separated at the same time. The "kino red" dyes mordanted cloth a series of browns, alumina giving the best colour. When fused with potash it forms protocatechuic acid, but not phloroglucinol. The sugar had no rotation, was reduced by Fehling's solution readily, was slowly but entirely fermented by yeast, and gave an osazone soluble in hot water, and which melted at 176—178° C. Were it not that it was inactive to light it might, from these reactions, be supposed to be melibiose, which is formed from melitose (*Eucalyptus* sugar) by hydrolysis, levulose being split off at the same time, This glucoside, for which the author proposes the name *Emphloin* (as it principally occurs in the bark of certain species), is found in almost a pure condition in those *Eucalypts* known as "Ironbarks." The kinos of the "Stringybarks" and of the "Peppermints," although consisting of the same tannin, do not contain sugar and are not glucosides, but the author has already isolated glucoside, *Myrticolarin*, from the "Stringybarks," the sugar of which is glucose. This kino glucoside is practically a bark product, occurring in species which do not appear to give *Eucalyptus* Manna. Melitose, however, is found in the bark of certain species in which the tannin is principally located in the wood, as in *E. punctata*. For these reasons the author thinks that melitose itself should be considered a glucoside, the third glucose molecule taking the place of the tannin in the glucoside. The quantitative results and the relative astringent values show the substance to contain an equivalent to two glucose molecules. Although entirely precipitated by gelatin, the glucoside has very slow action on hide, and thus the sluggishness of "Ironbark" liquors is accounted for. It now remains to devise a method whereby the glucoside may be cheaply hydrolysed, and thus the tannin in the bark of *E. sideroxyloides*, for instance, be made available for tanning purposes.

NOTICES OF BOOKS

Introduction to Physical Chemistry. By JAMES WALKER, D.Sc., F.R.S., &c. Third Edition. London: Macmillan and Co., Ltd. New York: The Macmillan Company. 1903. Pp. 368.

MODERN science tends more and more to bring together what were at one time looked upon as two separate sciences, viz., Chemistry and Physics, the result being now known as "Physical Chemistry." These is still, however, a strong tendency on the part of the student to keep his every-day chemistry and his physical chemistry apart. This is brought about to a great extent by the general methods of teaching adopted, by which what we may term the old chemistry is first drilled in, to be followed a few years after by the new ideas which seem only to complicate matters.

In this volume the author has endeavoured to smooth away the difficulties which beset the young student, and to bring out as clearly as possible the actual connection between the old and the new science, or perhaps more correctly to show how the latter has developed naturally from the former.

PROCEEDINGS OF SOCIETIES.

ROYAL SOCIETY OF NEW SOUTH WALES.

THE General Monthly Meeting of the Society was held at the Society's House, No. 5, Elizabeth Street North, on Wednesday evening, June 1st, 1904; C. O. BURGE, M. Inst. C.E., President, in the chair.

"On the Absence of Gum, and the Presence of a New Diglucoide in the Kinos of the *Eucalypts*," by HENRY G. SMITH, F.C.S., Assistant Curator, Technological Museum.

In this paper, which is the first of a series dealing with *Eucalyptus* kinos, the author shows that the supposed gum occurring in many *Eucalyptus* kinos is not gum but a peculiar tannin diglucoide. The insolubility in alcohol of this substance seems to have been the only reason for

The present edition differs from those that have preceded it in many points of detail. Newer data and more accurate numerical determinations have been adopted wherever available, and an additional chapter (Chapter XXVII.) has been written on electromotive force, while Chapter XXVIII., on thermodynamical proofs, dealing with the same subject, has been extended.

The book has been brought up to date as far as possible, and will no doubt attain as great success as the former editions.

A Method for the Identification of Pure Organic Compounds. By SAMUEL PARSONS MULLIKEN, Ph.D. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

THIS large volume represents an attempt at simplifying the labour of identifying organic compounds by giving systematised information concerning all known substances, classified together according to their behaviour when subjected to certain specified tests. Hitherto, when an investigator in the course of research has prepared a substance unfamiliar to him, in order to identify it he has been obliged to find its percentage composition and molecular weight, and then compare its properties with those of other compounds of the same empirical formula, which often entails consulting a large number of authorities, and is at the best a tedious and laborious process. The author of this work has devised a method of classification first of all into what he calls orders, *i.e.*, classes comprising compounds containing the same elements, then into genera, characterised by their behaviour on the application of certain chemical tests, and the various members of each genus are then tabulated according to the value of some readily determined physical constant, such as the melting- or boiling-points; various other characteristics of each member of the genus are also specified, and simple corroborative tests appended, so that the investigator should finally be able to be absolutely certain of the identity of his unknown substance, and that with comparatively little trouble. In the examples given of actual experiments performed, two typical though perhaps rather easy specimens were identified in one hour fifty minutes and two hours fifty-five minutes respectively, 0.8 gm. of the substance being consumed in each case. This speaks for itself when we consider the time that would probably be occupied in identifying an unknown substance by the old method, and, moreover, no account is taken of the fact that the investigator would probably have some clue as to the genus of his compound, which might shorten the labour considerably.

The collection of data concerning 2300 substances has, of course, involved an enormous amount of work, but exceeding conciseness and the judicious use of abbreviations have kept the book quite within the limits of ordinary size. This first part contains only the compounds of carbon with hydrogen, and with hydrogen and oxygen, and practically all such compounds are included excepting some uncrystallisable syrups which cannot be distilled without undergoing decomposition, the oily and fatty glycerides, and some glucosides and sugars, specimens of which could not be obtained for analysis. A second volume containing compounds of carbon with nitrogen, and nitrogen and oxygen, and a third to include the compounds of carbon with the other more important elements, are to be issued, and will, no doubt, with this be acceptable to the somewhat limited circle of readers to whom such works can appeal.

Jahrbuch der Elektrochemie. IX. Jahrgang. ("Electrochemical Annual." Vol. IX.). Edited by Dr. HEINRICH DANNEEL. Halle-a-S.: Wilhelm Knapp. 1904.

THIS volume, which contains the reports for the year 1902, has only just appeared, which greatly diminishes its value as an annual. As in preceding years, in it is discussed the progress which has been made during the year, both in

pure and applied electrochemistry, and improvements in apparatus and manufacturing processes are also fully described. It also contains the contributions which have been made to our knowledge of the theoretical aspects of the science, and a somewhat belated book review, chiefly relating to books which have appeared in Germany, though one American work receives rather a grudging notice. A vast amount of useful information is contained in the volume, which can lay claim to being comprehensive, and a full account of almost any point connected with electrochemistry could be obtained by looking it up in this book, for the leading current periodicals have been carefully searched and articles of interest and importance abstracted.

Atti della Società Elvetica di Scienze Naturali. ("Transactions of the Swiss Scientific Society"). Zürich: Zürcher and Furrer. 1904.

THIS volume contains the programme of the meetings of the Swiss Scientific Society, which held its eighty-sixth session at Lucerne in September, 1903, together with verbatim reports, either in German, French, or Italian, of the papers read before the general assembly; detailed accounts are given, in some cases copiously illustrated, of the commissions appointed to examine various questions of scientific interest, and also the reports of the auxiliary biological, geological, and chemical societies; these latter are sufficient to give an interesting insight into the workings and activity of a society which appears to combine in itself the vigour of youth with the stability of age. The biological sections in particular appear to be specially flourishing, and most of the papers and communications relate to this branch of natural science. The volume closes with biographical obituary notices of the members who have died in the years 1902 and 1903.

CORRESPONDENCE.

PEROXYLAMINESULPHONIC ACID.

To the Editor of the Chemical News.

SIR,—Permit me to point out a mistake in the first line of my paper on "Peroxylaminesulphonic Acid" (CHEMICAL NEWS, vol. xc., p. 42), which runs—"Although unrecorded in works on . . . chemical technology . . ." As a matter of fact, mention of the production of a violet colour in the acid in the Gay-Lussac tower is to be found in all three editions of Lunge's "Sulphuric Acid and Alkali." The treatment of the subject discussed in the paper is in no way affected by this statement in error; but, in correcting it, I desire to express my regret at having made it. At the time of writing the paper I was unable to make adequate references, and therefore invoked the aid of a most competent but busy friend in looking-up the matter for me, and he wrote that he could find nothing about the subject in Lunge's treatise. Professor Lunge has been good enough to inform me that he has also published an account of an investigation of the nature of this blue or purple colour in *Dingler's Journal* and in the *Berichte* in 1879. The colouration had already been noticed by C. Winkler and R. Weber. But Lunge ascertained that the production of the colour is due to interaction between sulphur dioxide, mercury (or other reducing agent), and nitrososulphuric acid, so far anticipating Sabatier's observations.—I am, &c.

EDWARD DIVERS.

Synthesis of Pentamethylene Glycol, $\text{HO}(\text{CH}_2)_5\text{OH}$, of Nitrile, and Pimelic Acid.—J. L. Hammett.—To obtain pentamethylene glycol the author transforms the dibromopentane into diacetate, and this, by saponification, into glycol.—*Comptes Rendus*, cxxxiv., No. 1.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxiv., No. 1, July 4, 1904.

Synthesis in the Anthracene Series. Dihydride of γ -Triphenylanthracene and Derivatives.—A. Haller and A. Guyot.—In a former research the authors described the preparation and chief properties of symmetric γ -diphenylanthracene dihydride and a few of its derivatives. They now continue their experiments, and describe the triphenyl derivatives and the conditions under which they are prepared. Theoretically they should be produced in several ways. These different methods are described in detail and the products obtained in each case.

Determination of the Atomic Weight of Nitrogen by Analysis by Volume of Nitrogen Protoxide.—Adrien Jaquero and M. St. Bogdan.—The authors determine the atomic weight of nitrogen by the volumetric analysis of one of the oxides of nitrogen. The method consists in decomposing nitrogen protoxide in an hermetically sealed tube by means of an iron wire heated by the electric current. The oxygen unites with the iron, leaving pure nitrogen. The weight deduced is 14.019 as the mean of all the experiments.

Allotropic Forms of Antimony Sulphide. Heat of Formation.—M. Guinchant and Chrétién.—The authors succeed in isolating a modification of antimony sulphide in a pure state; this is the stable form at a high temperature. The heat of formation is less than that of the black sulphide, the stable form at a low temperature. They also determine the heat of transformation of the different allotropic modifications of antimony sulphide when these pass to the stable form, admitting Berthelot's value for wet precipitated sulphide:—

$\text{Sb}_2 + \text{S}_3 \text{ oct.} + \text{H}_2\text{O} = \text{Sb}_2\text{S}_3 \text{ wet precipitate} \dots + 34.0 \text{ cal.}$
 From this the following numbers are deduced for 1 mol. or 336 grms.:—

$\text{Sb} + \text{S}_3 \text{ oct.} = \text{Sb}_2\text{S}_3 \text{ dry precipitate} \dots + 32.6 \text{ cal.}$

$\text{Sb}_2 + \text{S}_3 \text{ oct.} = \text{Sb}_2\text{S}_3 \text{ lilac precipitate} \dots + 33.9 \text{ cal.}$

$\text{Sb}_2 + \text{S}_3 \text{ oct.} = \text{Sb}_2\text{S}_3 \text{ black precipitate} \dots + 38.2 \text{ cal.}$

Action of Mixed Organo-magnesium Compounds on Phthalimide and Phenylphthalimide.—Constantin Béis.—In a preceding research the author showed that M. Grignard's mixed organo-magnesium compounds react on phthalimide, and that the products of this reaction, when treated with water, are decomposed into a body corresponding to—

This dehydration can take place in one of two ways:—

The author's experiments lead him to believe the latter to be the correct formula.

Action of Ammonia Gas on Arsenic Trichloride, Tribromide, and Triiodide.—C. Hugot.—Ammonia gas reacts at a low temperature on trichloride, tribromide, and triiodide of arsenic, giving arsenic amide. A chloride, bromide, or iodide of ammonium is formed at the same

time, according to the arsenic compound used. The amide thus prepared can be used to form also the imide and nitride of arsenic.

A Method of Decomposing the Lactic Acid of Fermentation into its Components Active to Polarised Light.—E. Jungfleisch.—The author describes a method of decomposing the lactic acid produced during fermentation into its active components. This method is founded on the difference in properties between *d*-lactate, *l*-lactate, and (*d*+*l*) lactate of quinine.

Iodine Compounds obtained with Metanitrilaniline.—P. Brenans.—The author prepares the following iodine compounds from metanitrilaniline:—(1) Di-iodonitrilaniline, $\text{NH}_2 \cdot \text{C}_6\text{H}_4\text{I}_2 = \text{NO}_2 \cdot 1.2.6.3$; (2) di-iodonitrobenzene, $\text{NO}_2 \cdot \text{C}_6\text{H}_3 = \text{I}_2 \cdot 1.2.4$; (3) di-iodoaniline, $\text{NH}_2 \cdot \text{C}_6\text{H}_3 = \text{I}_2 \cdot 1.2.4$; (4) Di-iodophenol, $\text{OH} \cdot \text{C}_6\text{H}_3 = \text{I}_2 \cdot 1.2.4$.

New Synthesis of α -Dimethyladipic Acid.—G. Blanc.—The author has previously shown that when $\text{C}_2\text{H}_5\text{O} \cdot \text{CO} \cdot \text{C}(\text{CH}_3)_2 \cdot \text{CO}_2 \cdot \text{C}_2\text{H}_5$, α -dimethylsuccinic ether,

is reduced by sodium and alcohol, a lactone, $\text{C}_6\text{H}_{10}\text{O}_2$, is formed besides the glycol. This lactone, when treated with potassium cyanide, gives α -dimethylglutaric acid by hydrolysis of the product of the reaction. The same method may be applied to dimethylglutaric ether, the resulting product being α -dimethyladipic acid.

Atmospheric Formaldehyde.—H. Henriet.—The author discovers an important objection to the accuracy of his former estimation of atmospheric formaldehyde, owing to the existence in the air of a compound of this aldehyde. He is continuing his researches on this question.

Bulletin de la Société Chimique de Paris.
 Series 3, vol. xxxi., No. 2.

Action of Isocyanate of Phenyl on some Univalent Alcohols. (II.)—A. Bloch.—The author easily obtained cholesterylphenylurethane by heating anhydrous cholesterol to 180° with isocyanate of phenyl. The net return was 70 per cent. With sulphuric acid it gives a bright orange-yellow colouration, becoming brown after fifteen or twenty minutes. When heated in a test-tube it decomposes and forms a white sublimate. Heated in the air it commences to decompose at about 280° , giving off carbonic acid slowly and regularly, till there finally remains a brown fluorescent liquid mass containing aniline, while on the sides of the tube there is a slight deposit of diphenylurea.

Action of the Diazo Chlorides in Excess in Alkaline Solution on Oxalacetic Ether.—J. Rabischong. Two-tenths of a molecule of aniline are dissolved in 50 c.c. of hydrochloric acid at 40 per cent, and treated with 100 c.c. of water. It is diazotised at 0° with two-tenths of a molecule of nitrite of soda and kept at this temperature. At the same time a tenth of a molecule of oxalacetate of ethyl, or 18.8 grms., is treated with 100 c.c. of a solution of soda of such strength as to saturate exactly the 50 c.c. of hydrochloric acid added to the aniline. This latter solution is cooled and the chloride of diazobenzene poured in very slowly. Gas is given off, and gradually a very thick, deep-red body is formed. The reaction continues for several hours, and the liquid takes the form of a soft mass. The substance is purified by two recrystallisations in absolute alcohol. Analysis gives it the formula of diphenylformazylformate of ethyl.

Action of the Diazo Chlorides on the Oxalacetic Ethers.—J. Rabischong.—A tenth of a molecule of aniline, or 9.3 grms., is dissolved in 25 c.c. of pure hydrochloric acid at 40 per cent, and treated with 50 c.c. of distilled water. This solution, cooled to 0° , is diazotised by a tenth of a molecule, or 6.9 grms. of nitrite of soda dissolved in 100 c.c. of water also cooled to 0° . At the same

the other, a brown salt, is altogether different, $(\text{S}_2\text{O}_3)_2\text{BiRb}_2\text{H}_2\text{O}$. The yellow salt is obtained in a similar manner to the potassium salt. The brown salt is formed by treating the yellow salt with a quantity of water insufficient to dissolve it. The two salts become anhydrous over P_2O_5 . The caesium salt, which is anhydrous, $(\text{S}_2\text{O}_3)_2\text{BiCs}$, is obtained by precipitating a nitric solution of nitrate of bismuth, nitrate of caesium, and hyposulphite of soda with alcohol. It is more stable than the salts of potassium and rubidium. The barium salt, $[(\text{S}_2\text{O}_3)_2\text{Bi}_2]\text{Ba}$, is obtained by the double decomposition of an alcoholic solution of a sodium salt and a solution of BaCl_2 ; the precipitate is pale yellow, and is strongly hydrolysable on contact with water; the solution deposits a basic salt. This compound, when pure, is fairly stable; when moist it decomposes rapidly into sulphide of bismuth and sulphate of barium.—*Zeit. Anorg. Chem.*, vol. xxxv., p. 1.

Pure Rhodium.—S. M. Jorgensen.—This metal is obtained by the reduction of the chloride $\text{Cl}(\text{Rh}_3\text{NH}_3)_2\text{Cl}_2$ by means of hydrogen. This chloride, prepared according to the method already described by the author (*Journ. f. Prakt. Chem.*, [2], vol. xxvii., p. 435), is not chemically pure, but contains a little iridium. The purification is easily effected by dissolving 10 grms. of the salt in 250 c.c. of NO_3H ($D = 1.40$), and heating on the water-bath until a small quantity diluted with water does not become cloudy with nitrate of silver. On cooling, we obtain the chloropentammonium nitrate. Dilute with its own volume of water, filter, and wash with NO_3H (1 vol. of acid, $D = 1.4 + 2$ vols. of water), then with alcohol. The salt obtained is dissolved in water and filtered, and the filtrate is collected in concentrated hydrochloric acid. The precipitated chloride, washed with dilute hydrochloric acid, then with alcohol after a second treatment with nitric acid, is dissolved in dilute soda and then precipitated by boiling with hydrochloric acid. Dissolve in boiling water and precipitate again with hydrochloric acid. After three dissolutions and re-precipitations the precipitate is free from soda and from HNO_3 .—*Zeit. Anorg. Chem.*, vol. xxxiv., p. 82.

VOL. XC., No. 2333.

THE ABSORPTION AND THERMAL EVOLUTION OF GASES OCCLUDED IN CHARCOAL AT LOW TEMPERATURES.*

By Sir JAMES DEWAR, M.A., D.Sc., LL.D., F.R.S.,
Jacksonian Professor, University of Cambridge, and Fellenius,
Royal Institution, London.

DURING the year 1874-5, in association with the late Professor Tait, a research was undertaken which involved the production of very perfect vacua, and with the object of improving on the then known methods, dense charcoal was employed as an efficient absorbent of traces of any gaseous residuum.

An account of these experiments communicated to the Royal Society of Edinburgh appeared in *Nature*, July 15, 1875, under the title of "Charcoal Vacua."

In Professor Clerk Maxwell's Notes on "Molecular Physics" the following succinct description of the process is given:—

"Another method employed by Professor Dewar is to place in a compartment of the vessel a piece of freshly heated cocoanut charcoal, and to heat it strongly during the last stages of the exhaustion by the mercury pump. The vessel is then sealed up, and as the charcoal cools it absorbs a very large proportion of the gases remaining in the vessel.

"The interior of the vessel, after exhaustion, is found to be possessed of very remarkable properties.

"One of these properties furnishes a convenient test of the completeness of the exhaustion. The vessel is provided with two metallic electrodes, the ends of which within the vessel are within a quarter of an inch of each other. When the vessel contains air at the ordinary pressure a considerable electromotive force is required to produce an electric discharge across this interval. As the exhaustion proceeds, the resistance to the discharge diminishes till the pressure is reduced to that of about a millimetre of mercury. When, however, the exhaustion is made very perfect, the discharge cannot be made to take

place between the electrodes within the vessel, and the spark actually passes through several inches of air outside the vessel before it will leap the small interval in the empty vessel. A vacuum, therefore, is a stronger insulator of electricity than any other medium."

At one of the conferences held in connection with the Special Loan Collection of Scientific Apparatus (see "Science Conferences," "Physics and Mechanics," p. 154) in the year 1876, I showed that with a vapour like bromine the absorptive power of the charcoal was so effective that a space filled with the vapour even at atmospheric pressure could be made into a fairly high vacuum showing very wide striae.

When the charcoal was heated the bromine vapour was again expelled, and on allowing it to cool, all stages in the appearance of the electric discharge as the vacuum is reached could be conveniently observed without the use of any form of air-pump.

When in the course of low temperature investigations the perfection of the vacuum vessels for the storage and manipulation of liquid air and hydrogen came to be important, the effect of charcoal on heat isolation in such utensils was fully investigated and confirmed in a paper entitled "Liquid Air as an Analytic Agent" (*Roy. Inst. Proc.*, 1898). Still no systematic experiments on the absorptive power of charcoal at low temperatures were made either at this time or subsequently.

It is the object of the present preliminary paper to contribute some definite quantitative data regarding gas absorption and thermal evolution in charcoal at the temperature of liquid air. The mode in which liquid gases like oxygen or air could be used as calorimetric agents was described in my paper on the "Scientific Uses of Liquid Air" (*Roy. Inst. Proc.*, 1894).

The apparatus was further improved into the form illustrated and described in Madame Curie's work, "Recherches sur les Substances Radio Actives," 2nd edition, p. 100, as used for the determination of the heat evolved by radium bromide either in liquid oxygen or hydrogen. Such calorimeters are easily adapted to the simultaneous observation of the volume of any gas absorbed by charcoal, and of the concomitant heat evolution.

For this purpose a small glass bulb, c, containing from 0.5-1 gram. of charcoal, has a long narrow tube, c', attached, so that it can be immersed in the liquid oxygen or air in the calorimeter, a b, while still allowing a part of the tube to project above the cork a. In order to dry and cool the 40 c.c. of gas, which represents the largest volume

* A Paper read before the Royal Society, June 16, 1904.

taken in by the charcoal in my experiments, a little annular space is arranged at D into which liquid air is poured immediately before the experiment is made.

The charcoal, after being placed in the tube, C, is heated to a low red heat and simultaneously exhausted by a good air-pump, and after all the gas has been removed the stopcock E is closed. In this condition it is placed in the calorimeter.

The experiment is conducted by connecting the end of the tube at E by means of an india-rubber tube with a graduated vessel, F, containing the gas. When all is ready the stopcock E is opened, so that the gas may rush into the charcoal, and the heat evolved by its absorption distils off the equivalent quantity of liquid air from the calorimeter, which is measured in the vessel G.

The constant of the calorimeter being known (which with liquid air is about 14.5 c.c. per calorie), we get the actual thermal evolution together with the volume of gas absorbed.

The heat correction for the rush of gas into the same exhausted glass bulb without charcoal is small in proportion to the total heat evolved, and the same may be said of the volume correction on account of the cooling of the space external to the charcoal. With a variable material like coconut charcoal, I have in the calorimetric experiments used the same sample in all cases. The following table embodies the general results per cubic centimetre of charcoal. The gas absorption is given at 0° and 760 m.m. If the volume of gas absorbed had been measured under the same conditions of pressure at -185° C., then the numbers in Column II. would all have to be divided by three.

	I. Volume absorbed. 0° C. C.c.	II. Volume absorbed. -185° C. C.c.	III. Heat evolved. Grm.-calories.
Hydrogen	4	135	9.3
Nitrogen	15	155	25.5
Oxygen	18	230	34.0
Argon	12	175	25.0
Helium	2	15	2.0
Electrolytic gas	12	150	17.0
Carbonic oxide and oxygen	30	195	34.5
Carbonic oxide	21	190	27.5

In all cases, it will be observed, the amount of gas occluded has been greatly increased at the low temperature, and the degree of condensation is generally such as we should anticipate from the known physical constants of the gases. The amount of heat evolved is so great as to be in excess of that required for liquefaction in the case of gases like hydrogen, nitrogen, and oxygen. The heat produced when successive fractions of the volume of gas required for saturation are absorbed has yet to be determined. In the time required for the absorption no measurable amount of chemical combination was effected between mixtures of hydrogen and oxygen or carbonic oxide and oxygen in the pores of the charcoal.

Such experiments must be extended to the use of platinised charcoal and other catalytic agents.

Perhaps the most striking result is the great difference in properties exhibited by helium. While resembling the other gases in showing increased absorption at the temperature of liquid air the absolute amount occluded per unit volume of charcoal is about one-tenth that of the other gases at the same temperature. There can be little doubt that when the relative absorption of helium in charcoal is measured at the temperature of liquid hydrogen, the increased absorption will be so marked as to make it comparable to that of hydrogen in the present set of experiments. In this case charcoal at the boiling-point of hydrogen will become an efficient condensing agent for helium, and this property will have important applications in future research.

Separation of Highly Concentrated Oxygen from Air.

In order to examine the changes taking place in a mixed gas like air during the absorption, a quantity of about 50 grms. of charcoal was, after heating and exhaustion, saturated at -185° in a current of pure dry air; got by passing the air current through a U-tube immersed in liquid air.

For a time the air rushed into the charcoal with great rapidity, and in about ten minutes between 5 and 6 litres were taken in. A manometer attached to the vessel containing the charcoal showed, on shutting off the air current, that during the early part of the saturation the absorption was so effective as to give practically no measurable mercury pressure. As soon as the absorption was ended, and a current began to pass slowly over the charcoal, the composition of the air leaving the charcoal showed 98 per cent nitrogen. After the current of air had passed for half an hour, the total gas occluded in the charcoal was expelled by taking the vessel in which it had been treated out of the liquid air, and allowing the temperature to rise to 15° C.

The gas, which was rapidly expelled, measured 5.7 litres, and contained 56 per cent of oxygen. If the saturated charcoal before heating up was subjected for an hour to the action of an air-pump, capable of giving a steady exhaustion of 5 m.m., no difference was effected in the oxygen percentage of the evolved gas. The same experiment was repeated with this variation, that, instead of the air current having the pressure of the atmosphere, it was kept below one-tenth of an atmosphere. In this experiment 4.8 litres were expelled on heating up, and the percentage of oxygen was 58. Then a further repetition was made with an air current supplied at a pressure not exceeding 5 m.m. of mercury. After three hours' treatment the charcoal, on heating to 15° C., gave 44 litres of 57 per cent oxygen. From these experiments it follows that the tension of the occluded gases, at the temperature of liquid air, must be very small, and thus the use of low temperatures, combined with charcoal, introduces a new and greatly improved means of getting high vacua, which in the future may be found susceptible of important practical applications. These experiments are quite conclusive as to the practical constancy of the mean composition of the air gases occluded in the charcoal (subject to the conditions aforesaid), and they further show that wide changes in the pressure of the air current has little or no effect in altering the proportions. In another experiment, the vessel containing the saturated charcoal, instead of being allowed to rise rapidly in temperature, was transferred to a vacuum vessel, in which a little liquid air was placed, in order that the temperature might rise slowly, and thereby enable the successive litres of gas given off to be collected separately and analysed.

This experiment gave the following results:—

	Oxygen, per cent.
First litre	18.5
Second litre	30.6
Third litre	53.0
Fourth litre	72.0
Fifth litre	79.0
Sixth litre	84.0

The mean composition of the 6 litres is again 56 per cent oxygen. From the above experiments it follows that one of the most rapid means of extracting a high percentage of oxygen from atmospheric air is to absorb it in charcoal at low temperatures, and then to expel it either rapidly or slowly by heating the mass of charcoal to the ordinary temperature.

A few experiments have been made, using, instead of air, special mixtures of oxygen and nitrogen. Thus it was found that a gas containing 6.5 per cent of oxygen used in the same manner as in the air occlusion experiments gave, on heating up the charcoal rapidly to 15° C., 5 litres of gas having the composition of 23 per cent of oxygen. A

repetition of the same process with the 23 per cent of oxygen would have raised the percentage about 60 per cent, or a stronger concentration could have been reached by fractionating the gas as it slowly leaves the charcoal on gradually increasing the temperature.

This preliminary investigation suggests many fields for further inquiry, and some of these I hope to deal with in future papers.

I have to express my thanks to Mr. Robert Lennox, F.C.S., for efficient aid in the conduct of the experiments, and Mr. J. W. Heath, F.C.S., has also rendered valuable assistance.

A REVISION OF THE ATOMIC WEIGHT OF BERYLLIUM.*

By CHARLES LATHROP PARSONS.

(Concluded from p. 64).

II. Determinations of the Atomic Weight.

SINCE the last investigation of the atomic weight of beryllium was made by Krüss and Moraht, in 1890, two new anhydrous compounds of beryllium have been discovered which are especially fitted for a re-determination of this constant, viz., the acetylacetonate and the basic acetate. The first has the disadvantage common to all compounds previously used, in that it contains a small per cent of beryllium, slightly less than the sulphate, in fact, and any variation in the per cent of beryllium oxide is doubled in the atomic weight. The basic acetate fortunately contains a much larger proportion of beryllium, and in this respect approaches to the composition of the chloride. Both are readily crystallised and sublimed, and lend themselves to a very complete separation of the element from others, which might interfere in the determination. The basic acetate, a compound with very unusual properties and peculiar to beryllium alone, would seem to be especially adapted for this purpose.

The Properties and Analysis of Beryllium Acetylacetonate.

Properties.—Beryllium acetylacetonate was first prepared by Combes (*Comptes Rendus*, cxix., 1221), the discoverer of acetylacetonate itself (*Ibid.*, ciii., 814), and many of the interesting metallic derivatives of that compound. It is most readily prepared by the action of beryllium carbonate or hydroxide on acetylacetonate. It is a perfectly white crystalline substance which is slightly soluble in cold water, more soluble in hot water, and slowly decomposed by boiling water with loss of acetylacetonate and precipitation of beryllium hydroxide. It is readily soluble in alcohol, and is easily crystallised therefrom in rhombic plates, differing widely from the crystals of the corresponding aluminum salt. It is soluble in benzene, toluene, xylene, naphtha, and all petroleum distillates, coloriform, turpentine, methyl alcohol, amyl alcohol, ether, ethyl acetate, acetone, carbon disulphide, and all other solvents at my disposal. It melts at 108°, and boils at 270° without decomposition (Combes, *Comptes Rendus*, cxix., 1222). It sublimed readily many degrees below its boiling-point, and begins to sublime even below the boiling-point of water. The sublimed crystals are light and flocculent, with a marked resemblance to flakes of snow. It is soluble in acids, setting free acetylacetonate.

Preparation of Material.—Two separate lots of material were prepared for the atomic weight determinations.

1. Basic beryllium carbonate, prepared as before described from beryl, was carefully washed with ammonia-free water until absolutely free from sulphates, and while still moist was treated with Kahlbaum's acetylacetonate, which was first re-distilled. Carbon dioxide was slowly evolved, and the insoluble beryllium acetylacetonate left

behind. This was pulverised and washed with pure water to remove excess of acetylacetonate, and was then dissolved in re-distilled absolute alcohol, and filtered to remove any unchanged carbonate. On partial evaporation, beryllium acetylacetonate was deposited. The clear plate-like crystals showed no colour, but were again pulverised, washed with water, dissolved in absolute alcohol, and re-crystallised. This operation was repeated for the third time, and the mother-liquors each time rejected. The crystals so produced were absolutely free from iron, and not the slightest residue of aluminum chloride could be obtained by Havens' method of separation (*Zeit. Anorg. Chem.*, xvi., 15—18). They were pulverised and dried for several hours in an air-bath. After drying they were introduced into a Jena glass retort, connected with a receiver of the same material, and were sublimed in a current of dry carbon dioxide many degrees below their boiling-point. The retort was heated evenly on a bath of rosin kept at 230°, and the neck of the receiver was covered with a piece of silk bolting-cloth, which allowed only the carbon dioxide to pass. The perfectly white light and feathery acetylacetonate was again introduced into the freshly prepared apparatus, melted and re-sublimed. The sublimed crystals were kept over phosphorus pentoxide until ready for use.

2. Kahlbaum's "Berylliumhydrat," containing a small amount of iron and some aluminum hydroxide, was treated direct with acetylacetonate. The reddish colour of the iron salt became immediately apparent, and the main part of the beryllium hydroxide was converted into the acetylacetonate. Some aluminum hydroxide was also converted into aluminum acetylacetonate, although Urbain and Debiere state that the aluminum derivative is not easily prepared from the hydroxide (*Comptes Rendus*, cxix., 302—305). The acetylacetonate was dissolved in alcohol, filtered, and crystallised, rejecting the mother-liquor which contained almost all of the small amount of iron and aluminum acetylacetonates. The deep red colour of the iron salt is a very delicate test for the presence of iron, even the slightest traces in an otherwise apparently pure beryllium carbonate being made evident at once by the yellowish tinge of the acetylacetonate. The crystals, still slightly coloured, were pulverised and washed in water in which the iron salt is much more soluble, and again crystallised from alcohol. This was repeated until crystals were obtained which yielded a clear colourless solution in absolute alcohol. These crystals were re-crystallised three times, as in preparation 1, were dried, sublimed, and re-sublimed, as already described. No evidence of any impurity could be found.

The Analysis.—The analyses were carried out in platinum crucibles without any transfer of material. The crucibles had been ignited for several hours in an atmosphere of hydrochloric acid gas containing a small amount of chlorine, to remove iron, after which they were submerged in fused acid potassium sulphate, cleaned, and finally boiled in concentrated hydrochloric acid. Light glass weighing bottles were procured of a convenient size to contain these crucibles, and in each was placed a thin porcelain dish, so that the crucibles could be enclosed in the weighing-bottles while still warm without danger of fracturing the glass. A platinum cone was weighed with each crucible. Before each weighing, the weighing-bottles and contents were placed in a desiccator over phosphorus pentoxide, the desiccator being so constructed that the bottles could be closed before removal, and the air of the desiccator, which always contains some moisture after being opened, replaced by perfectly dry air before the crucibles had cooled. The crucibles were placed in the desiccator warm before each weighing, except the initial weighing of the acetylacetonate.

Beryllium acetylacetonate is not hygroscopic, nor is the oxide, although Nilson and Petersen seem to have had a contrary experience (*Ber.*, xiii., 1451). Still every precaution was taken to have the conditions of weighing as nearly identical as possible. As before stated, all weighings were made by the method of substitution and

* From the *Journal of the American Chemical Society*, xxvi., No. 7.

against a tare treated in like manner and of the same material and shape, and of but slightly greater mass than the weighing-bottles and contents against which it was balanced. The crucible forming a part of the tare was not blasted.

After standing for some hours in the desiccator, the weighing-bottles, containing the empty crucibles and cones, were closed, removed, placed in the balance case, and after standing for one-half hour were weighed. The acetylacetonate was now placed in the crucibles, and the whole returned to the desiccator and allowed to stand for at least twelve hours, when they were again closed, removed, and weighed. Although subsequent weighings were always made, there was no further loss in weight.

The crucibles were then taken from the weighing-bottles, and re-distilled pure nitric acid, leaving no residue on evaporation, was added. The acetylacetonate dissolved to a perfectly colourless solution, which was diluted with twice its own volume of water, that had been re-distilled through block-tin and caught in platinum. The crucibles and contents were then placed upon a small platinum dish in an air-bath at 50°. It was kept at this temperature for from twenty-four to forty-eight hours, a further addition of water being once made. During this heating the acetylacetonate was almost completely evaporated. Any considerable rise in temperature caused the nitric acid to attack the liberated acetylacetone, decomposing it with foaming, which invariably ruined the determination. If the temperature was carefully regulated, however, no trouble whatever was experienced. After the removal of the acetylacetone, the temperature was slowly raised during another forty-eight hours to 100°, which served to remove most of the remaining liquid, leaving a clear glucose-like nitrate already basic in character from loss of nitric anhydride.

Perforated platinum cones, previously weighed with the crucibles, and of such size and shape that when inserted they fitted tightly in the crucibles above the nitrate, were now placed in an inverted position in the crucibles and the temperature again gradually raised during several hours to 175°. The use of the cones was thought advisable from noticing in a preliminary experiment that the last traces of water escaped through the viscous material in small bubbles, and it was thought that possibly in breaking, a loss might occur through spurting. The inner surface of the cones showed no trace of this, however, when later removed. The heating to 175° left the nitrate as a slightly porous white solid which had already lost more than 75 per cent of the nitric anhydride, equivalent to the beryllium present. The crucible was next supported in a Jannasch beaker upon a platinum triangle, and slowly heated over a Bunsen burner to decompose the last traces of nitrate, which was accomplished at a low heat and without any danger of loss of material. The crucible and contents were finally placed inside of a second platinum crucible, as recommended by Brauner (*Ann. Chem. Soc.*, lxxxi., 1249), to prevent loss of weight of the crucible itself, as Beilstein (*Chem. Centrbl.*, 1880, p. 614) and Hall (*Journ. Am. Chem. Soc.*, xxii., 496) have shown can so easily occur, and the whole blasted at a bright red heat until the crucible and contents showed no further loss of weight.

Corrections.—All weights are corrected to a vacuum standard, and the weights of beryllium oxide are also corrected for occluded gases.

Specific Gravity.—Unexpected difficulty was encountered in determining the specific gravity of the beryllium acetylacetonate, as no liquid could be found in which it was insoluble. It was but very slightly soluble in water at 20°, and it was found necessary to determine its specific gravity in an aqueous solution of itself at this temperature. This was not all that could be desired, but gave results which vary but little from the truth, and introduce an error into the subsequent corrections of weight so small that it can be entirely disregarded. In determining the specific gravity of the water, saturated with beryllium acetylacetonate, the pycnometer was filled to a mark on its outer surface and

evacuated for the same length of time as employed in the actual determinations of the specific gravity of the solid. No acetylacetonate separated. The pycnometer was then filled as usual, and its weight determined. The average of closely agreeing determinations gave sp. gr. $\text{Be}(\text{C}_2\text{H}_3\text{O}_2)_2 = 1.168$ compared to water at 4°. The determination of the specific gravity of beryllium oxide needs no special comment. Krüss and Morath obtained the value 2.9644 (*Liebig's Ann. Chem.*, cclxii., 57). My results gave sp. gr. $\text{BeO} = 2.9640$, compared to water at 4°.

Occluded Gases.—Richards has shown that oxides, derived from the ignition of nitrates, contain occluded nitrogen and generally oxygen (*Am. Chem. Journ.*, xx., 702). Beryllium oxide is no exception to this rule, but the conditions of its formation by the very slow and gradual decomposition of the nitrate were peculiarly favourable to the removal of these gases. Gas was evolved on solution in strong sulphuric acid to the extent of 0.35 c.c. for each grm. of beryllium oxide, of which almost exactly one-third was soluble in alkaline pyrogallate. A correction was therefore made on the weights obtained of 0.00047 grm. per grm. of BeO .

The Properties and Analysis of Beryllium Basic Acetate.

Properties.—This unique and interesting chemical compound appears to be peculiar to beryllium alone. It was discovered by Urbain and Lacombe in 1901 (*Comptes Rendus*, cxxxiii., 874), and Lacombe a year later, (*Ibid.*, cxxxiv., 772), produced the basic formate, propionate, butyrate, isobutyrate, and isovalerianate of the same type. The formate having the highest percentage of beryllium would be excellent for determining the relative proportion of that element, but unfortunately it sublimates at so high a temperature, and consequently condenses so quickly, that it is extremely difficult to purify, especially as it is quite easily decomposed, even under much reduced pressure, at the temperature required for its sublimation. The basic acetate, however, has properties peculiarly fitting it for very complete purification, and also contains nearly twice as great a percentage of beryllium as any substance heretofore used for the determination of the atomic weight.

Basic beryllium acetate, $\text{Be}_2\text{O}(\text{C}_2\text{H}_3\text{O}_2)_6$, melts at 283—284°, and boils at 330—331° (*Comptes Rendus*, cxxxiii., 874), and is readily sublimed without decomposition. It is itself almost insoluble in water, but is slowly hydrolysed by cold water, and quickly by hot, after which it dissolves. It is easily soluble, unchanged in absolute alcohol and in chloroform, and is soluble in all the solvents already mentioned for the acetylacetonate (see ante). It is also soluble in acetic anhydride and glacial acetic acid. Although a basic compound, its solution in glacial acetic acid can be saturated with hydrochloric acid gas and remain unchanged. It has not been found possible to produce the normal salt. It is unaffected in dry air. Ordinary acids attack it, setting free acetic acid, probably through the agency of water they contain. It is much more soluble in boiling glacial acetic acid than in cold, and is most readily crystallised in this manner. On cooling, it separates from boiling glacial acetic acid as small shining grains which, under a magnifying glass, are seen to be almost perfect octahedrons.

Preparation of Material.—1. Basic beryllium carbonate

prepared, as already described, from "Kahlbaum's hydrate" was dissolved in pure concentrated hydrochloric acid, ether added, and the small amount of aluminum, which it still contained, was separated by Havens' method (*Zeit. Anorg. Chem.*, xvi., 15-18; *Am. Journ. Sci.*, 4, v., 111-114). The pure chloride was precipitated by ammonia, dissolved in ammonium carbonate, ammonium sulphide added, allowed to stand, filtered, and boiled to precipitate the carbonate. The carbonate so produced was thoroughly washed with carefully purified water, and dissolved in excess of Kahlbaum's "Eisessig," which had been re-distilled and which left no residue on evaporation. The excess of glacial acetic acid was boiled off, with constant stirring, by means of a Bunsen burner held in the hand under the porcelain evaporator, and the residue dried. A large excess of glacial acetic acid was now added and boiled. Solution immediately took place, and, on cooling, the basic salt crystallised out in small shining octahedrons, which in the mass much resembled granulated sugar. The mother-liquor was rejected and the crystals washed with cold glacial acetic acid. They were again twice dissolved in hot, and re-crystallised in cold glacial acetic acid, rejecting the mother-liquors, and washing as before. The basic acetate so produced was dried at 150° to remove all excess of acid. It was then twice sublimed in Jena glass under a pressure of 250 m.m., and in a current of dry air free from water and carbon dioxide. The sublimation was brought about by means of a bath of cylinder oil maintained at a temperature varying little from 290°. The perfectly white crystalline product so obtained was kept over phosphorus pentoxide until wanted.

2. Another lot of the acetate was prepared in a manner differing little from that already described, except that it was sublimed at normal pressure, and the bath kept at 305-310°.

Analysis of the Basic Acetate.—The method used for the analysis of the basic acetate was almost identical with that employed for the acetylacetate. The initial temperature was 70°, however, as the decomposing action of the nitric acid was no longer to be feared. At this temperature most of the acetic acid was removed, but to be sure that no acetate remained undecomposed, concentrated nitric acid was added twice more, and the evaporation repeated. The basic acetate dissolved readily in nitric acid to a colourless nitrate.

Corrections.—The specific gravity of the basic beryllium acetate was determined in gasoline in which liquid it is less soluble than in any other investigated. Unfortunately, it is slightly soluble in this liquid, 50 c.c. dissolving 0.054 grm., and the gasoline was first saturated with the basic acetate before its own gravity was determined. Closely agreeing results yielded specific gravity $\text{Be}_2\text{O}(\text{C}_2\text{H}_3\text{O}_2)_6$ 1.362. Determinations of the gases, occluded by the oxide produced from the basic acetate, agreed with those from the acetylacetate. In fact, the figure given is the average of several results on both. The variation of all results was from 0.32 to 0.39 c.c. per grm. of oxide. Occluded gases = 0.0047 grm. per grm. BeO .

Samples of the oxide produced from both the beryllium acetylacetate and the basic acetate were dissolved in pure hydrochloric acid, and sent to Prof. Charles C. Hutchins, of Bowdoin College, who kindly consented to examine them with the special spectroscopic facilities at his command. He reported that they were absolutely free from iron and aluminum, and that he was unable to find any other impurity. My acknowledgment and sincere thanks are due to him for this part of the work.

In connection with this investigation I have prepared a bibliography of beryllium, with abstracts, which I believe to be complete, and which will shortly be published separately.

THE OCCURRENCE OF PLATINUM IN
WOLLASTONITE ON THE ISLAND OF SUMATRA,
NETHERLANDS EAST INDIES.*

By L. HUNDESHAGEN.

WHEN visiting Western Sumatra in 1901, the author's attention was drawn to the unusual conditions under which a deposit of wollastonite and grossularite occurs, and, on the opportunity arising, a further study of the ground was made last year (1903). The deposit is situated near the high road, at the Singenggo river, west of the village Moeara Sipongi (Japanoei), and about 35 English miles from the sea coast, and in former times was mined by the Malays. It contains gold, also small quantities of platinum.

The main features of the ore deposit, which is composed chiefly of grossularite, are the following:—

At 30 m. to the south-west occur old schists, having a strike of north 70° W. These are older than the granites which in many parts of the district are met with at the same or at a much higher elevation. To the north the ore deposit has been sharply and almost vertically cut off by a well-defined dyke of hornblende rock, which is in some places slightly silicified, but contains no garnet, and shows no transition into the ore body. On the west the ore deposit is covered by a cap of a blackish angite-diorite, under which in one place a little granite outcrops, while almost the whole is buried under the products of an enormous extinct volcano. Its crater-lake on the Malintang mountain is 1.2 km. long and 0.7 km. wide, and lies 19 km. due south. Far to the north of the ore deposit, primitive and Cambrian schists are met with, and also some remnants of the carboniferous limestone series.

Upon a consideration of the facts, the author is of opinion that the present ore deposit was originally a layer, or a big lens, of limestone imbedded in the old schists, which has, by apophyses of granite, been altered into garnet and wollastonite, being at the same time, or very soon afterwards, mineralised by hot solutions carrying copper, gold, platinum, &c. This Singenggo ore deposit, therefore, differs in some respects from other garnet,

* A Paper read before the Institution of Mining and Metallurgy, July 21, 1904.

wollastonite deposits (mostly from 9 to 15 km. distant) which all belong to the carboniferous limestone series, and may, though very old, be considerably younger than the Singingoe deposit.

The almost horizontal but undulated zone of contact between the grano-diorites and limestones has been fairly well disclosed by both ancient and recent workings, which have also exposed some long apophyses of diorite and wollastonite. All the characteristics of a very intense, although local, metamorphism are noticeable at the base of both the carboniferous limestone and the clay slates. The more recent auriferous garnet and wollastonite contact deposits referred to never seem to carry the platinum metals, although they frequently contain copper, and sometimes traces of nickel and cobalt.

The Singingoe ore, which assayed platinum, is composed of the following minerals:—

85 per cent to 88 per cent wollastonite, interlaced sometimes with bornite; 12 per cent to 14 per cent grossularite.

Traces to 5 per cent bornite, with secondary incrustations of copper glaucite.

Traces of magnetite, iron pyrites, manganese (braunite and rhodonite),* and calcite. Arsenic being absent, nothing points to the presence of sperrylite. Occasionally vugs and veins of calcite occur, with large crystals of pyroxene.

The analysis of a practically pure sample of colourless tough wollastonite gave:—

	Per cent.
Loss after heating	0.02
SiO ₂	51.48
CaO	47.61
Oxide of manganese	0.60
Magnesia	Minute trace*
Oxide of iron and alumina	0.24

The absence of magnesia in a platinum ore is rather striking, the more so as white and yellow pure serpentine rocks are met with in the vicinity in primitive schists, and, further, because a well-crystallised white magnesite occurs only a few hundred metres from the Singingoe wollastonite deposit. Besides, carbonate of magnesia sometimes occurs here in contact deposits containing copper and iron pyrites, asurite, magnetite, &c.

It may further be worth mentioning that a sample of slightly decomposed wollastonite with no copper, or only minute traces of that metal, proved to be richest in platinum, the assay showing:—

6 grms. Pt per 1000 kilos.
4 " Au "
2 " Ag "

while, on the other hand, selected samples with 2 to 10 per cent of bornite and malachite contained—

15 to 2300 grms. Au per metric ton,
15 to 560 grms. Ag "

and only traces of platinum.

Auriferous garnet, poor in wollastonite, appears to contain no platinum.

In this section no platinum could be detected under the microscope; nor could any be seen when finely powdered ore was concentrated in the wooden batea.

About 10 to 25 m. from the outcrop, the concentrated river sand shows small particles of whitish crystalline gold and rounded grains of white platinum, the latter varying from 0.1 to 0.3 m.m. in size.

In Western and South-Eastern Borneo, where platinum is met with in diamond placers, it is not found in the form

of grains, but in thin scales, ranging from 0.1 to 1.0 m.m. in thickness.

These platinum scales contain amongst other usual metals, copper varying from 3.8 to 4.5 per cent, evidently as an alloy, since the copper cannot be extracted by strong nitric acid.

Although peridotites (serpentine) abound in Borneo, no platinum could be found by the author in their close vicinity, but only traces of gold and metallic copper. The diurnal platiniferous placers are found at a considerable distance, say 10 to 30 km., from the deposit described.

All this points to the probability that in the Indian Archipelago the occurrence of platinum is unusual, and that where found the metal is not derived from serpentines.

METHOD FOR THE ESTIMATION OF PRUSSIAN BLUE.

By CH. COFFIGNER.

FOLLOWING my paper on the solubility of Prussian blue (*Bull. Soc. Chim.*, vol. xxvii., p. 696) appeared a note by M. Wyruboff (*Ibid.*, p. 940), in which, before asking certain questions to which I am about to give an answer, he remarked that he had already announced the solubility of Prussian blue in hydrochloric acid.

At the time I published my paper I was unaware of M. Wyruboff's work, and I had read in the principal textbooks on chemistry, as well as in special works on the colour industry, that Prussian blue was insoluble in hydrochloric acid.

M. Wyruboff states that it would be interesting to submit solutions of blue in mixtures of HCl + fatty alcohols to the action of cold. I had already thought of that, and had asked M. Claude to be good enough to submit solutions containing 20 grms. per litre to the lowest possible temperatures. In every case the result obtained was invariable: solidification of the solution without any change of colour.

When we add a small quantity of water to alcoholic solutions, the Prussian blue is precipitated. M. Wyruboff asks whether the solution contains ferric chloride.

I have entirely re-examined this question of precipitation by water, using blues from Berlin sold as pure by different makers.

I dissolved 0.5 grm. of blue in 50 c.c. of solvent, precipitated with water, washed until all acid reaction disappeared, and collected the precipitate on a tared filter.

The following results were obtained with the same blue:—

Alcohols used.	Weight of blue obtained.
Isobutylic	0.487 grm.
Amylic	0.498 "
Propylic	0.480 "

The filtration is very difficult. After the second washing the blue will not settle, and it is impossible—even after passing it through the filter several times—to obtain a perfectly colourless filtrate. I have tried using double filters, or the addition of a known quantity of sulphate of baryta, without obtaining any better results.

I succeeded in the filtration, without any loss, by using alcohol for the second and subsequent washings. This simple plan succeeds perfectly, and if, in very rare cases, the first liquor passes a little blue, it is sufficient to wait until the next day; the blue, in small amount, becomes united on the surface or at the bottom, and is easily collected on the filter.

I have operated on several blues of different manufacture in this manner, always using the same dissolving mixture—hydrochloric acid and propylic alcohol, this alcohol having the advantage over amylic alcohol of its greater solubility in water. The following are the results obtained:—

* In some samples of the garnet rock more recently analysed, after separation from the accompanying minerals, the garnet has been found to contain 0.19 per cent of magnesia (MgO), which small proportion is, according to the author's theory, to be accounted for by the biotite of the intrusive granite.

Mark.	Weight of blue dissolved.	Weight of blue recovered.	Blue, per cent.
B.	0.5	0.490	98.0
B.	0.5	0.491	98.2
P.	0.5	0.502	100.4
P.	0.5	0.502	100.4
S.	0.5	0.501	100.2
S.	0.5	0.502	100.4
M.	0.5	0.498	99.6
M.	0.5	0.501	100.2

These results make it clear that it is possible to use dissolving mixtures as a method of estimation.

The principal blue colours containing Prussian blue are the following:—

Charron blue ..	Prussian blue and sulphate of baryta.
Mineral blue ..	Prussian blue, kaolin, and sulphate of baryta.
Paris blue ..	Prussian blue and alumina.
Blue fecula ..	Prussian blue and starch.

These compositions are not absolute and may vary with different makers; but, on the whole, besides pure blue, we find sulphate of baryta, carbonate of lime, sulphate of lime, kaolin, alumina, and starch.

I have prepared the following series of mixtures with one or more of the above-mentioned substances:—

1.	Prussian blue	1.400 gm.
	Sulphate of lime	0.600 "
2.	Prussian blue	1.200 "
	Kaolin	0.800 "
3.	Prussian blue	1.000 "
	Starch	1.000 "
4.	Prussian blue	0.550 "
	Sulphate of lime	0.200 "
	Carbonate of lime	0.200 "
	Kaolin	0.600 "
	Alumina	0.450 "
5.	Prussian blue	0.300 "
	Carbonate of lime	1.700 "
6.	Prussian blue	0.250 "
	Sulphate of baryta	1.750 "
7.	Prussian blue	0.150 "
	Kaolin	0.400 "
	Sulphate of baryta	1.000 "
	Alumina	0.400 "
	Carbonate of lime	0.050 "
8.	Prussian blue	0.060 "
	Sulphate of baryta	1.940 "

I attacked 2 grms. of each of the above mixtures with 100 c.c. of the solvent. When the whole of the blue had gone into solution I made the bulk up to 200 c.c. If the charge goes into solution with the blue, as in the case of the carbonate of lime and the starch, I take 100 c.c. and precipitate with water; the blue only is precipitated. If the charge is not attacked, I filter, collect 100 c.c. in a graduated flask, and precipitate with water. After washing with water and alcohol until the acid reaction has disappeared, the blue is collected on a tared filter and weighed after drying in the oven at 100°. The following results were obtained with the mixtures of which the composition is given above:—

No.	Amount of blue used.	Amount of blue found.
	Per cent.	Per cent.
1	70.0	69.80
2	60.0	60.30
3	50.0	50.20
4	27.5	27.45
5	15.0	14.80
6	12.5	12.30
7	7.5	7.45
8	3.0	2.70

I used this method for the analysis of a commercial "Charron blue," and I found—

Moisture	0.22
Insoluble portion	94.82
Prussian blue	4.30
	99.34

Not at all a bad result when we consider that the natural sulphate of baryta which forms the insoluble portion always contains a little sulphate of lime and oxide of iron.

Remarks.

When we have to deal with a blue containing alumina, the solution takes place much more slowly. For example, if we take 1.600 grms. of Prussian blue and 0.400 gm. of alumina, it is impossible to get all the blue into solution with 100 c.c. of the solvent, even when prolonging the boiling for a considerable time. On the other hand, the solution is soon effected by replacing the alumina by the same proportion of sulphate of baryta, kaolin, &c.

The quantity of water to be added to effect the precipitation varies according to the richness of the solution. I have been surprised at the large amount of water necessary to precipitate solutions slightly concentrated. For this reason I have determined, as accurately as possible, the amount of water necessary to precipitate 50 c.c. of solutions of different strengths. The following table gives the figures obtained:—

Strength of the solution	Water necessary.	Strength of the solution.	Water necessary
Per cent.	C.c.	Per cent.	C.c.
0.1	79.0	0.7	14.5
0.2	46.5	0.8	12.5
0.3	26.5	0.9	11.0
0.4	23.5	1.0	8.0
0.5	20.5	1.5	5.5
0.6	17.0	2.0	2.5

As we add the water the solution becomes deeper and deeper in colour, passing to reddish brown, and finally to deep green immediately before the precipitation of the blue. These changes of colour, especially with solutions of slight concentration, make it very difficult to seize the exact moment of precipitation. The rapidity with which the water is introduced is also a factor to be considered. Finally, it may also be remarked that a smaller quantity of water allows the precipitation to go more slowly.

If we construct a curve, making the abscissae the strengths of the solutions, and the ordinates the number of cubic centimetres of water necessary for their precipitation, we observe a very rapid fall for solutions of 0.1, 0.2, and 0.3 per cent. After this, the variations become very regular.

The liquor separated from the blue precipitate is colourless or of a very slight greenish tint. On concentration it changes to yellow. When all the alcohol has been driven off by boiling, the liquid, almost completely neutralised with carbonate of soda, contains ferric chloride, which is easily detected by means of ferrocyanide and sulphocyanide.

The figures given above prove the complete precipitation of the blue, so that we can only attribute the presence of iron in the aqueous portion to two causes:—(1) To the presence of small quantities of ferrous chloride, which is to be found in nearly every sample of Prussian blue; (2) to a decomposition of a small portion of the blue by hydrochloric acid.

I have been able to prove these suppositions by experiment. For the first, it suffices to exhaust the Prussian blue with water; the aqueous portion gives a slight white precipitate with ferrocyanide—if not with all commercial blues, at any rate with a large number of them. To prove the second case I dissolved a few milligrams of blue in a large excess of hydrochloric acid. The solution is not precipitated by water. When concentrated and neutralised, ferrocyanide and sulphocyanide both give the characteristic reactions of the ferric salts.—*Bull. Soc. Chim.*, Series 3, vol. xxi., No. 7.

THE MECHANICAL ANALYSIS OF SOILS.

By JOHN GEDDES MCINTOSH.

Too much stress should not be given to the mechanical analysis of soils. Man is not an automatic machine, and I am afraid few chemists would get identical results with the same soil in succession. That they do not get it by adopting different methods each of which is a standard method in its way is evident from the following results with the same soil from the neighbourhood of Pisa, quoted by Peligot:—

	I. Per cent.	II. Per cent.	III. Per cent.
Sand	1'47	32'07	13'35
Clay	87'31	37'67	71'90
Earthy carbonates	—	20'20	—
Organic and volatile matter	9'66	10'25	—
Undetermined	—	—	14'75
Soluble matter and loss	1'56	—	—
	100'00	100'19	100'00

I. Nobel's process. II. Schloesing's process. III. Masure's process.

Working with an upward current of water I have found comparative results cannot be obtained unless the pressure of the current of water remain constant, a desideratum difficult to realise. Moreover, the data afforded by a mere mechanical analysis of the soil tells nothing either to the chemist or farmer. No one is able to picture in his mind's eye the appearance and properties of a soil from its mechanical analysis. An expert agriculturist by a single glance at a soil can form an opinion regarding it far more superior and valuable than any which he, aided by the most expert agricultural chemist extant, can possibly form from inspecting the results of a mere mechanical analysis alone. Land valuers do not make mechanical analysis of soils.

Analytical Laboratory,
9, Parsonage Street, Cubitt Town, E.

ANALYSIS OF KUNZITE.

By R. O. E. DAVIS.

At the request of Professor Charles Baskerville, Director of the Chemical Laboratory, I undertook the chemical analysis of kunzite, the new and beautiful variety of spodumene, described by Kunz and himself (see *Am. Journ. Sci.*, vol. xviii., July, 1904; also *Science*, 1903, xviii., 303 and 769). The methods used were those given in Hillebrand's excellent "Principles of Rock Analysis" (*Bull. U. S. Geol. Survey*, No. 176), and need not be re-stated here.

A selected, clean, deep lilac-coloured crystal, quite free from flaws, was ground to an impalpable powder and used in the analytical work. Following are the figures obtained:—

	Per cent.
SiO ₂	64'05
Al ₂ O ₃	27'30
NiO	0'06
MnO	0'11
ZnO	0'44
CaO	0'80
MgO	none
K ₂ O	0'06
Na ₂ O	0'30
Li ₂ O	6'88
Loss on ignition	0'15
Total	100'15

No chromium, vanadium, titanium, iron, strontium, barium, thorium, zirconium, or phosphorus was found. On account of the unique properties possessed by the mineral the other rare earths were looked for. Dr. W. J. Humphreys, of the Rouss Physical Laboratory of the University of Virginia, kindly photographed the arc spectrum obtained from the material which had been freed from silicon and lithium. He reported none of the characteristic lines of cerium and yttrium groups present. The material lost its pink colour on ignition.—*American Journal of Science*, vol. xviii., July, 1904.

THE BRITISH SCIENCE GUILD.

It has been a frequent subject of comment that, although the contribution of this country to the progress of science has been second to that of no other nation, the English people do not manifest that interest in, and belief in the powers of science, which are noticeable among the peoples of the Continent, or of America. In spite of the efforts of many years, the scientific spirit, essential to all true progress, is still too rare, and, indeed, is often sadly lacking in some of those who are responsible for the proper conduct of many of the nation's activities. It is with the view of attempting to remedy this evil, and to bring home to all classes the necessity of applying scientific treatment to affairs of all kinds, that the proposal is made to bring together those convinced of this necessity by founding "The British Science Guild."

The objects and organisation of the Guild, which will be entirely disconnected from party politics, are as follows:—

Objects.

1. To bring together as members of the Guild all those throughout the Empire interested in science and scientific method, in order, by joint action, to convince the people, by means of publications and meetings, of the necessity of applying the methods of science to all branches of human endeavour, and thus to further the progress and increase the welfare of the Empire.
2. To bring before the Government the scientific aspects of all matters affecting the national welfare.
3. To promote and extend the application of scientific principles to industrial and general purposes.
4. To promote scientific education by encouraging the support of universities and other institutions where the bounds of science are extended, or where new applications of science are devised.

Methods of Attaining these Objects.—(a) By publications; (b) by Meetings; (c) by Conferences and Lectures; (d) by Deputations.

Organisation.

Admission of Members.—All British subjects, both men and women, are eligible for membership of the Guild; it is expected, however, that its members will be recruited principally from the following:—

The House of Lords; the House of Commons; Colonial Legislatures; County, District, Borough, and Parish Councils; Municipalities; Educational Committees; Scientific and Literary Societies and Organisations; Commercial and Industrial Chambers and Organisations; the Learned Professions; Universities, Colleges, Educational Bodies, and Graduates of all British Universities; Representatives of Labour.

At a meeting of the promoters of the Guild, held, by permission of the Officers, at the Rooms of the Royal Society, on April 20th, 1904, it was decided that the steps preliminary to the formation of the Guild should be taken by an Organising Committee, of which the following were appointed members, with power to add to their number:—Lord Avebury, F.R.S.; Professor W. E. Ayrton, F.R.S.; Sir George Sydenham Clarke, K.C.M.G., F.R.S.;

Captain E. W. Creak, R.N., C.B., F.R.S.; Mr. Clive Cuthbertson; Dr. William Garnett; Mr. Sidney Lee; Sir Norman Lockyer, K.C.B., F.R.S.; Lady Lockyer; Mr. N. Maccoll; Professor Raphael Meldola, F.R.S.; Professor J. Perry, F.R.S.; Sir Gilbert Parker, M.P.; Sir William Ramsay, K.C.B., F.R.S.; Dr. W. N. Shaw, F.R.S.; Professor S. P. Thompson, F.R.S.; Dr. Augustus Waller, F.R.S.; Sir Henry Trueman Wood.

The Organising Committee has elected Sir Norman Lockyer, President; Lord Avebury, Honorary Treasurer; Lady Lockyer, Honorary Assistant Treasurer; and Mr. C. Cuthbertson, Honorary Secretary.

It was resolved that Life Members of the Guild shall pay, on admission, two guineas, which includes a registration fee of 2s. 6d. and that Annual Subscribers shall pay, on admission, 5s., and in each subsequent year 2s. 6d. It was also resolved that donations may be accepted.

The Committee are now engaged in communicating with those corporate bodies and individuals whose support and sympathy are desired.

A General Committee will be appointed, which will subsequently select from among its members an Executive Committee for the management of the affairs of the Guild. The Executive Committee will meet from time to time as their Chairman may direct, and will formulate such rules as experience may suggest, for the approval of the General Committee.

The General Committee will probably take power to appoint or approve local and special committees, which will act as branches of the Guild.

The following have already signified their general approval of the objects and proposed organisation of the Guild:—

The Right Honourable Lord Alverstone, G.C.M.G.; The Right Honourable Lord Avebury, F.R.S.; Professor Ayrton, F.R.S.; Sir John Wolfe-Barry, K.C.B., F.R.S.; Dr. W. Blandford, F.R.S.; Sir James Blyth, Bart.; Mr. Brabrook, C.B.; Sir George Birdwood, K.C.I.E.; Sir John Brunner, Bart.; Sir Lauder Brunton, F.R.S.; Major-General Sir Owen Tudor Burne, G.C.I.E.; Sir Edward Busk; Mr. R. H. Caird; Sir William Church, Bart., K.C.B.; Sir George Sydenham Clarke, K.C.M.G., F.R.S.; The Hon. Sir John Cockburn, K.C.M.G.; Captain Creak, R.N., C.B., F.R.S.; Mr. Clive Cuthbertson; Professor W. E. Dalby; Dr. Ferrier, F.R.S.; Sir Michael Foster, M.P., F.R.S.; Dr. William Garnett; Sir Archibald Geikie, F.R.S.; Sir Robert Giffen, K.C.B., F.R.S.; Mr. Hammond-Chambers, K.C.; Professor Herdman, F.R.S.; Professor J. Larmor, F.R.S.; Dr. Sidney Lee; Sir Norman Lockyer, K.C.B., F.R.S.; Lady Lockyer; Dr. Lockyer; Mr. Maccoll, Professor R. Meldola, F.R.S.; Sir A. Noble, Bart., K.C.B., F.R.S.; Sir Gilbert Parker, M.P.; Professor Perry, F.R.S.; Sir William Ramsay, K.C.B., F.R.S.; The Lord Ray, G.C.S.I.; Sir Wemyss Reid; Sir William Richmond, K.C.B., R.A.; Sir Henry Roscoe, F.R.S.; Mr. E. Robertson, M.P.; Sir A. Rucker, F.R.S.; Dr. W. N. Shaw, F.R.S.; Mr. Alex. Siemens; The Lord Strathcona and Mount Royal; Sir L. Alma Tadema, R.A.; Professor Silvanus P. Thompson, F.R.S.; Dr. A. D. Waller, F.R.S.; Field-Marshal Viscount Wolseley, G.C.B.; Sir Henry Trueman Wood.

ascertained all the following physical properties of specimens of tempered steels, which had previously been very carefully analysed, viz., the microstructure, density, elasticity, hardness, electrical resistance, and magnetic properties, and gives in this volume the results obtained with such general conclusions as can be drawn from them. In successive chapters the methods of determining these constants are described, and the results obtained experimentally discussed at length, and finally an attempt is made to classify these properties and to draw conclusions of practical interest, especially as regards methods of testing steels, a subject of great technological importance. Though the actual outcome of the experiments does not appear to be any generalisation of much value, a great deal of careful work, both experimental and literary, has evidently been done in preparing this thesis.

Beiträge zur Chemischen Physiologie und Pathologie. ("Contributions to Chemical Physiology and Pathology"). V. Band, 7 and 8 Heft. Edited by FRANZ Hofmeister. Braunschweig: Friedrich Vieweg und Sohn. 1904.

This number of the *Beiträge* contains many papers of great interest to physiological chemists. Among them may be mentioned one by Dr. Kammann on the hay fever poison contained in rye pollen. The author undertook researches to determine the proportion of this poison to the other constituents of the pollen, and to examine its characteristic properties. He is satisfied that he has proved that the poison is a toxalbumen, stable towards acids and enzymes, and capable of being heated to 70° without being destroyed. A most interesting paper on a subject of great importance is that by Sigval Schmidt-Nielsen, on the behaviour of the enzymes towards concentrated electric light. The experiments described were performed with Finsen's apparatus, as described in the "Mitteilungen aus Finsens Medizinischem Lichtinstitut," the enzymes examined being chymosin, chymosinogen, and anti-chymosin. This attack on some of the problems of light biology, though it shows conclusively that these enzymes are very easily influenced by concentrated electric light, unfortunately has, so far, given only somewhat contradictory results as concerns the question of the increase of the quantity of enzyme by physical means; nevertheless, a mass of valuable material has been collected, and further research may explain some of the difficulties which have cropped up in the course of the investigation. The same author communicates a short notice on the effect of radium rays on chymosin, in which he shows that exposure to such rays causes a slight but perceptible diminution in the effect of the ferment, i.e., increases the time of coagulation of goat's milk. A series of experiments carried out in the botanical institute of the University of Tokio is described by Dr. K. Shibata, who has succeeded in proving the existence in the mycelium of *Aspergillus niger* of an enzyme or enzymes capable of splitting off ammonia from urea, biuret, and some acid amides. To this group of enzymes, which he is further investigating, he proposes to give the name "amidases."

A Compendium of Chemistry, including General, Inorganic, and Organic Chemistry. By Dr. CARL ARNOLD. Translated by JOHN A. MANDEL, Sc.D. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

It is not easy to see what class of readers can be supposed to regard the purchase of this book as a profitable investment. It cannot be recommended for use as a text-book by students, being too condensed and too full of individual details regarding an immense number of substances to the exclusion of the consideration of general principles, except perhaps as regards the section on general chemistry, which contains a good deal of useful matter well put together, and though quite unobjectionable in most respects it presents no special novelty of treatment to recommend it.

NOTICES OF BOOKS

Recherches Physiques et Physico-chimiques sur l'Acier au Carbone. ("Physical and Physico-chemical Researches on Carbonised Steel"). By CARL BENEDICKS. Uppsala: Librairie de l'Université. 1904.

IN order to explain the relations of the physical properties of iron and steel to their chemical constitution, the author of this thesis rightly considers the logical method to adopt is to determine as many different properties as possible of the same specimen. Going upon this principle he has

While being too detailed for a students' text-book, as a work of reference it can hardly be regarded as sufficiently comprehensive, and chemists would probably prefer to possess a more specialised volume devoted exclusively to one branch of chemistry, though the fact that the original has run through eleven editions certainly shows that in some circles its merits, or rather its lack of demerits, are appreciated.

Chémie der Eiweisskörper. ("The Chemistry of the Albuminous Substances"). By Dr. OTTO COHNHEIM. Second Edition. Braunschweig: Friedrich Vieweg und Sohn. 1904.

ALTHOUGH only a few years have elapsed since the publication of the first edition of this work, our knowledge of the chemistry of the albumens has developed so rapidly as to render advisable the preparation of a second edition, for which it has been necessary to re-write many chapters, especially in that part of the book which describes the physical properties, constitution, and decomposition products of the albuminous substances in general. In the special part also a good many alterations have been made, which all tend to add to the value of the work, which is well qualified to hold a unique place in the literature devoted to this branch of chemistry. Current periodicals have been thoroughly well searched, some of the references even being to papers which appeared only in the early part of this year.

Die Galvanoplastik. ("Galvanoplastic"). By Dr. W. PFANHAUSER. Halle-a-S.: Wilhelm Knapp. 1904.

THE author of this monograph shows himself to be thoroughly conversant with the ins and outs of his subject, and is evidently competent to write authoritatively on it. Though the task of preparing this volume might easily have degenerated into a mere abstracting of patent literature, Dr. Pfanhauser has contrived to infuse quite another spirit into his work, and, while giving all necessary details regarding apparatus and methods, he has very wisely omitted to make mention of every modification of only slight importance; as, for example, in dealing with the constituents and their proportions in galvanoplastic baths, for which such numerous recipes differing to only a trifling extent are given by various authors. The methods of industrial importance are everywhere emphasised, and the short chapters on the applications of the process to the preparation of gramophone records, artificial teeth, &c., are written in a thoroughly practical spirit, which indeed is a marked characteristic of the whole book.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 2, July 11, 1904.

Thermo-chemical Investigations on Solution and Polymerisation of Cyanogen.—M. Berthelot.—The author measures the loss of energy when—(1) Cyanogen reacts on water, (2) potassium cyanide reacts on dissolved cyanogen, (3) cyanogen reacts on alcohol, and (4) potassium cyanide reacts on an alcoholic solution of cyanogen.

Condensation of Glycol Bromacetate with Acetoacetic and Acetonedicarbonic Ethers.—A. Haller and F. March.—When glycol bromacetate reacts on the sodium derivatives of methylenic compounds, products are obtained in which the quantity $-\text{CH}_2-\text{CH}_2\text{O}.\text{CO}.\text{CH}_3$ remains unchanged. In the case of sodium acetoacetic ethers

γ -acetoxybutyrate of the acetyl- α -acetyl are obtained according to the equation—

Compounds which, with semicarbazide, give a single pyrazolone melting at 163° :—

Densities of Sulphurous Anhydride and Oxygen.—Adrien Jaquero and Alexandre Pintza.—The authors re-determine the density of sulphurous anhydride and oxygen. In the case of oxygen the mean of five experiments gives the value 1.4292 grms. as the weight of a litre of this gas at 0° and under a normal pressure (latitude 45° and at sea level). The concordance of the individual results is not so good as in the case of sulphurous anhydride—the maximum exceeding the mean by $1/3000$ part. This fact possibly proves the existence of traces of solid particles in the gas, which causes the mean value to be slightly higher than numbers obtained by other experimenters—Lord Rayleigh, 1.42907 ; Leduc, 1.4288 ; Morley, 1.42900 . The number obtained for sulphurous anhydride under the same conditions is 2.92664 .

Heat of Combustion of Sulpho-organic Compounds.—P. Lemoult.—The author measures the heat of combustion of amyl mercaptan, amyl sulphide, methyl sulphocyanate, and other organic sulpho-compounds by applying the following formula:—For compound $\text{C}_x\text{H}_y-\text{a}(\text{N}_m\text{H}_a)_n$, the heat of combustion is given by $z = 102x + \frac{55}{2}y + (16.5m - 10a) + 151n$.

Reactions of $\alpha\beta$ -Diketo-butyric Ethers. I. Action of Phenylhydrazine.—L. Bouveault and A. Wahl.—In a preceding research the authors showed that the action of nitrous anhydride on acetylacetic ethers under certain conditions leads to the formation of $\alpha\beta$ -diketo-butyric ethers, $\text{CH}_3-\text{CO}-\text{CO}-\text{COOR}$. They also found that these ethers react with phenylhydrazine in the cold, giving mono-phenylhydrazones, of which the constitution has not been established. Diketonic ethers contain two carbonyl groups capable of reacting with phenylhydrazine, and it is apparent that the constitution of the hydrazones corresponds to one of the two formulæ,—

according as the reaction takes place on the α - or β -carbonyl group. The authors' experiments prove this to be the case.

Researches in the Pyrane Series.—E. E. Blaise and H. Gault.—The authors obtain certain simple derivatives in the pyrane series, beginning with the first term of the

series, pyrane, $\text{O} < \begin{array}{c} \text{CH}=\text{CH} \\ \text{CH}=\text{CH} \end{array} > \text{CH}_2$. Their experiments were

first attempted on dicarboxyl-1.7-diketonic-2.6-acids, from which the pyranic acids should be obtained, the condensation being effected with 1.5-diketones, and which should result in the cyclohexenones. These experiments were not satisfactory, and they therefore condensed the different aldehydes with oxalacetic ether.

Certain Phenolic Ethers with Pseudo-allylic Chain, $\text{R}-\text{C}(\text{CH}_3)=\text{CH}_2$.—MM. Béhal and Tiffeneau.—During the reaction of methyl-magnesium iodide on the corresponding ether salts, besides the tertiary alcohols, $\text{R}-\text{C}(\text{OH})(\text{CH}_3)_2$, a larger or smaller quantity of a pseudo-allylic derivative, $\text{R}-\text{C}(\text{CH}_3)=\text{CH}_2$, is obtained. In

order to obtain a maximum amount of this latter substance, the authors find it necessary to use one or two extra molecules of the methyl-magnesium iodide. They obtain the following bodies, and find their boiling-points, densities, and indices of refraction:—

	Boiling-point.	Density.	Refractive index.
Ortho-pseudo-allylanisol	198—199	0.983 at 21°	1.5315
Meta-pseudo-allylanisol.	215—216	1.009 at 0°	1.5417
Para-pseudo-allylanisol.	223	Melts at 32°	1.5423

Action of a Trace of certain Salts and Caustic Alkalis on Diphenylcarbonic Ether.—R. Fosse.—In a preceding research the author discovered that when diphenylcarbonic ether is heated in contact with a small quantity of dry sodium carbonate, a curious transformation into carbonic anhydride, phenol, and phenylorthophenoxycarbonate takes place quantitatively, according to the reaction $2\text{CO}_2(\text{C}_6\text{H}_5)_2 = \text{CO}_2 + \text{C}_6\text{H}_5\text{OH} + \text{C}_6\text{H}_5\text{O}-\text{C}_6\text{H}_5$. The author now extends his experiments, and investigates the effect of traces of other substances—trisodic phosphate, disodic arsenate, sodium bi- and tetra-borate—on diphenylcarbonic ether.

Berichte der Deutschen Chemischen Gesellschaft.
Vol. xxxvii., No. 10, 1904.

Fatty Aromatic Diazo-amido Compounds (Triazines).—Ludwig Wolff and Hans Lindenhayn.—If 50 grms. of diazo-benzene-imide to which 200 grms. of alcohol have been added, are heated to boiling with a solution of 30 grms. of potassium cyanide and 5 grms. of potassium hydroxide in 50 grms. of water for half-an-hour, and then about half the alcohol distilled off, on cooling glittering scales of the potassium salt of 1-phenyl-2-cyantriazine separate out. The triazine itself is obtained by the addition of hydrochloric or acetic acid to the ice-cold, very dilute solution of the potassium salt. It is very unstable, and gradually changes into a brown mass insoluble in soda. From the potassium salt the methyl ester was also prepared. The latter gives methylaniline, nitrogen, and cyanic acid on addition of acids or bases; on the other hand, the phenyl-cyantriazine itself gives, with mineral acids in the cold, diazobenzene and urea. Hence, the two substances probably differ in constitution, as shown by the formulæ $\text{C}_6\text{H}_5\text{N}:\text{N}:\text{NH}:\text{CN}$ and $\text{C}_6\text{H}_5\text{N}(\text{CH}_3)\text{N}:\text{N}:\text{CN}$. The authors are led to think that the potassium salt and the free acid are similarly constituted, though they cannot positively prove this.

Notes on Ammoniacal Platinum Compounds.—Hans and Astrid Euler.—On evaporation of the filtrate from Magnus's salt from the saturated ammonium chloride solution, a brick-red powder separates out, if platinum chloride, as well as platinumous chloride, is present (Grimm). If the aqueous solution of the red powder, even when saturated with ammonium chloride, is evaporated, the residue consists partly of yellowish-red scales and partly of a yellow crystalline powder. These crystals have the same empirical composition as Grimm's red powder, $\text{Pt}(\text{NH}_3)_4\text{Cl}_4$. The scales have the same percentage of platinum as the yellow powder, from which about half the chlorine may be precipitated with silver nitrate. If fairly concentrated sulphuric acid is added to the solution of the yellow salt fine red needles separate out, which become white and opaque in cold water and turn red again in hot concentrated sulphuric acid, and are therefore chloro-diplatinamine sulphate. Hence the yellow substance, which is formed by transposition from Grimm's red powder, is chloro-diplatinamine chloride.—

and not a double salt of ammonium platinous chloride and ammonium chloride.

The Action of Silicon on Water below 100°.—H. Moissan and P. Siemens.—If pure amorphous silicon or

powdered silicon crystals are treated with distilled water at 95° in a glass vessel, after six to twelve hours some silicic acid is formed, the water being decomposed. If very thin transparent yellow crystals are used, such as Vigouroux describes (*Ann. de Phys. et de Chim.*, 1897, [7], xii., 64), it may be seen under the microscope that each crystal is coated with a thin layer of the hydrate. The decomposition of water by silicon may also be shown by the following method:—Powdered silicon was placed on the bottom of a glass vessel and distilled water poured on it. A little funnel was immersed with the mouth downwards, the tube being bent downwards and closed. The whole was carefully filled with distilled water, and heated to 95—98° on the water-bath. After some hours, bubbles could be seen on the surface of the silicon. These soon collected in the funnel-tube, and could be shown to consist almost entirely of hydrogen. The analysis of the oxidation product obtained showed that it was silicic acid. The experiment was repeated with different specimens of silicon, and the same result obtained. But if a platinum vessel was used, the water being previously distilled in a platinum retort, no decomposition took place, nor in glass vessels if a trace of fluoric acid was present. On the other hand, the water was decomposed in platinum vessels if distilled water containing a drop of caustic soda or potash or ammonia was used. This behaviour is explained by supposing that the small quantity of alkali in the glass gives rise to the following reactions, the alkaline silicate being decomposed by water forming SiO_2 : $\text{Si} + 2\text{NaOH} + \text{H}_2\text{O} = \text{SiNa}_2\text{O}_3 + 2\text{H}_2$. Thus a very small quantity of alkali can convert a comparatively large quantity of silicon into SiO_2 with evolution of hydrogen.

NOTES AND QUERIES.

*. Our Notes and Queries column was opened for the purpose of giving and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertisement columns.

Artificial Silk.—I should be greatly obliged if any reader could inform me where I can obtain any information on the "alkali-cellulose" process of manufacturing artificial silk. I am practically familiar with the Chardonnet and Lenher methods.—S. Moss.

CHARTERED INSTITUTE OF PATENT AGENTS.

The Qualifying Examination of persons desirous of being registered as Patent Agents will be held in NOVEMBER next. A Notice giving full particulars has appeared in the "Illustrated Official Journal" (Patents) of July 27, 1904, and a copy of such Notice can be obtained on application to the SECRETARY, Chartered Institute of Patent Agents, Staple Inn Buildings, London, W. C.

PATENTS, DESIGNS, AND TRADE MARKS ACTS, 1883 TO 1888.

NOTICE IS HEREBY GIVEN that

JAMES YATE JOHNSON, of 47, Lincoln's Inn Fields, in the County of London, seeks leave to Amend the Specification of Letters Patent No. 1487 of 1903 granted to him for "Improvements in the Manufacture of Explosives."

Particulars of the proposed amendment were set forth in the Illustrated Official Journal (Patents) issued on August 4th, 1904.

Any person, or persons, may give Notice of Opposition to the Amendment (on Form G), at the Patent Office, 25, Southampton Buildings, London, W. C., within one calendar month from the date of the said Journal.

G. N. DALTON,
Comptroller-General.

JOHNSONS and WILLCOX,
47, Lincoln's Inn Fields, London, W. C.,
Agents for the Applicant.

Young Man (22), Inter. Sc. (Lond.), Registered

Student of Inst. of Chem., thorough training in general Inorganic and Organic, Gas, Water, and Sugar Analysis, desires Post as Junior Chemist in an Analyst's Laboratory. Sound knowledge of Theory, and good references as to ability.—Cecil Wigham, 8, All-farthing Lane, Wandsworth.

UNIVERSITY OF BIRMINGHAM.

SCHOOL OF METALLURGY.

Professor—THOMAS TURNER, M.Sc., A.R.S.M.

Lecturer—O. F. HUDSON, A.R.C.S.

Assistant Lecturer and Demonstrator—GUY RICKETTS,
M.A., A.R.S.M.

A VACATION COURSE IN PRACTICAL METALLURGY will be held at the new METALLURGICAL SMELTING HOUSE, Bournbrook, Birmingham, in SEPTEMBER next. The course will commence on Monday, September 5th, and will last for about six weeks. The regular hours of instruction will be from 9 a.m. to 4 or 5 daily, but attendance may be required at any other time during day or night, as may be found necessary.

For those who already possess some knowledge of Metallurgy, it is believed that the course will afford opportunities which have not hitherto been available in this country.

Fees:—For Students of the University £4 4 0
 External Students (including Entrance Fee). . . £5 5 0

Further particulars may be obtained from the SECRETARY.

THE
DURHAM COLLEGE OF SCIENCE.
 NEWCASTLE-UPON-TYNE.

Complete Courses of Instruction are provided for Students of both sexes proceeding to the University Degrees in Science, or in Letters, and for the University Diploma in Theory and Practice of Teaching. Special facilities are offered for the study of Agriculture, Applied Chemistry, Mining, and all branches of Engineering and Naval Architecture.

Matriculation and Exhibition Examinations begin September 26th. Lectures begin October 4th, 1904.
 Prospectuses on application to the SECRETARY.

REDRUTH SCHOOL OF MINES, CORNWALL.

Session 1904-1905 begins September 7th.

A "Mining Certificate" is awarded to Students passing successfully through the School Course. **PRACTICAL MINING CLASSES**, under the instruction of Capt. WILLIAM HAMBY (late Government Inspector, South Africa). Distinctions in Mine Surveying in Open Examination five years in succession, including five Medals and Prizes, being all the awards of the City and Guilds of London Institute in 1904 in this subject. SYLLABUS and every information on application to—
 THE REGISTRAR.

FROM STOCK

in

1, 2½, & 5 m.g.

Tubes.

ON HIRE,

or at

REASONABLE PRICES.

Pitchblende, from 2/- to 30/- per piece; in Powder, 2/6 per oz.
 Kunzite, (select), 2/- per gramme. Carnotite, 2/- per oz.
 Aeschynit, 2/- per oz.
 Sparteite (See NATURE, March 31, 1904, page 523), 2/- per piece.
 Chlorophane, 2/- per piece. Samarakite, 2/- per oz.
 Zinc Sulphide, green and yellow, 2/6 per tube.
 Rad. Residue, 2/- per tube. Polonium, 21/- per gram; 11/- ½-gram.
 Polonium on Bi rod, 25/- Willemite, 2/- per oz.
 Flexible Sandstone, 3/- to 50/- (See NATURE, June 23, 1904, page 15).

Monazit, 3/- per oz. Monazit Sand, 1/- per oz.
 Diamond chips and powder, 10/- per carat (best quality).
 Euklas, Hiddent, Wagnerit, Phosgenit.
 Bar. Plat. Cyan., for Screens, 3/- gramme, 60/- oz. Crystals, 4/- gramme. Screens, 9d. per square inch.
 Rad.-active Screens, 6d. per square inch. Willemite Screens 6d. per square inch. Electroscopes (special), 21/-.
 Spinthariscopes (special), 21/-, 10/6 and 7/6.
 Selection of Minerals in Boxes, 2/6, 5/6, 10/6 and 21/-.

NEW ZEALAND VEGETABLE CATERPILLAR; from 2 to 3 inches long, with a stem showing fructification growing out of its head. Specimens may be had from 10/6 to 21/-, according to quality and size.

See NATURE, May 12, 1904, page 44.

Goods may be returned if not approved of, when money will be refunded.

VOL. XC., No. 2334.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

CAMBRIDGE, 1904.

INAUGURAL ADDRESS OF THE PRESIDENT,
THE RIGHT HON. A. J. BALFOUR, D.C.L., LL.D., M.P.,
F.R.S., Chancellor of the University of Edinburgh.

Reflections Suggested by the New Theory of Matter.

THE meetings of this great Society have for the most part been held in crowded centres of population, where our surroundings never permit us to forget, were such forgetfulness in any case possible, how close is the tie that binds modern science to modern industry, the abstract researches of the student to the labours of the inventor and the mechanic. This, no doubt, is as it should be. The interdependence of theory and practice cannot be ignored without inflicting injury on both; and he is but a poor friend to either who undervalues their mutual co-operation.

Yet, after all, since the British Association exists for the advancement of science, it is well that now and again we should choose our place of gathering in some spot where science rather than its applications, knowledge, not utility, are the ends to which research is primarily directed.

If this be so, surely no happier selection could have been made than the quiet courts of this ancient University. For here, if anywhere, we tread the classic ground of physical discovery. Here, if anywhere, those who hold that physics is the true *Scientia Scientiarum*, the root of all the sciences which deal with inanimate nature, should feel themselves at home. For, unless I am led astray by too partial an affection for my own University, there is nowhere to be found, in any corner of the world, a spot with which have been connected, either by their training in youth, or by the labours of their maturer years, so many men eminent as the originators of new and fruitful physical conceptions. I say nothing of Bacon, the eloquent prophet of a new era; nor of Darwin, the Copernicus of Biology; for my subject to-day is not the contributions of Cambridge to the general growth of scientific knowledge. I am concerned rather with the illustrious line of physicists who have learned or taught within a few hundred yards of this building—a line stretching from Newton in the seventeenth century, through Cavendish in the eighteenth, through Young, Stokes, Maxwell, in the nineteenth, through Kelvin, who embodies an epoch in himself, down to Rayleigh, Larmor, J. J. Thomson, and the scientific school centred in the Cavendish laboratory, whose physical speculations bid fair to render the closing years of the old century and the opening years of the new as notable as the greatest which have preceded them.

Now what is the task which these men, and their illustrious fellow-labourers out of all lands, have set themselves to accomplish? To what end led these "new and fruitful physical conceptions" to which I have just referred? It is often described as the discovery of the "laws connecting phenomena." But this is certainly a misleading, and in my opinion a very inadequate, account of the subject. To begin with, it is not only inconvenient, but confusing, to describe as "phenomena" things which do not appear, which never have appeared, and which never can appear, to beings so poorly provided as ourselves with the apparatus of sense perception. But apart from this, which is a linguistic error too deeply rooted to be easily exterminated, is it not most inaccurate in sub-

stance to say that a knowledge of Nature's laws is all we seek when investigating Nature? The physicist looks for something more than what, by any stretch of language, can be described as "co-existences" and "sequences" between so-called "phenomena." He seeks for something deeper than the laws connecting possible objects of experience. His object is physical reality; a reality which may or may not be capable of direct perception; a reality which is in any case independent of it; a reality which constitutes the permanent mechanism of that physical universe with which our immediate empirical connection is so slight and so deceptive. That such a reality exists, though philosophers have doubted, is the unalterable faith of science; and were that faith *per impossibile* to perish under the assaults of critical speculation, science, as men of science usually conceive it, would perish likewise.

If this be so, if one of the tasks of science, and more particularly of physics, is to frame a conception of the physical universe in its inner reality, than any attempt to compare the different modes in which, at different epochs of scientific development, this intellectual picture has been drawn, cannot fail to suggest questions of the deepest interest. True, I am precluded from dealing with such of these questions as are purely philosophical by the character of this occasion, and with such of them as are purely scientific by my own incompetence. But some there may be sufficiently near the dividing line to induce the specialists who rule by right on either side of it to view with forgiving eyes any trespasses into their legitimate domain which I may be tempted, during the next few minutes, to commit.

Let me, then, endeavour to compare the outlines of two such pictures, of which the first may be taken to represent the views prevalent towards the end of the eighteenth century; a little more than a hundred years from the publication of Newton's "Principia," and, roughly speaking, about midway between that epoch-making date and the present moment. I suppose that if at that period the average man of science had been asked to sketch his general conception of the physical universe, he would probably have said that it essentially consisted of various sorts of ponderable matter, scattered in different combinations through space, exhibiting most varied aspects under the influence of chemical affinity and temperature, but through every metamorphosis obedient to the laws of motion, always retaining its mass unchanged, and exercising at all distances a force of attraction on other material masses, according to a simple law. To this ponderable matter he would (in spite of Rumford) have probably added the so-called "imponderable" heat, then often ranked among the elements; together with the two "electrical fluids," and the corpuscular emanations supposed to constitute light.

In the universe as thus conceived, the most important forms of action between its constituents was action at a distance; the principle of the conservation of energy was, in any general form, undreamed of; electricity and magnetism, though already the subjects of important investigation, played no great part in the Whole of things; nor was a diffused ether required to complete the machinery of the universe.

Within a few months, however, of the date assigned for these deliverances of our hypothetical physicist, came an addition to this general conception of the world, destined profoundly to modify it. About a hundred years ago Young opened, or re-opened, the great controversy which finally established the undulatory theory of light, and with it a belief in an interstellar medium by which undulations could be conveyed. But this discovery involved much more than the substitution of a theory of light which was consistent with the facts for one which was not; since here was the first authentic introduction into the scientific world-picture of a new and prodigious constituent—a constituent which has altered, and is still altering, the whole

* The hypothesis of an ether was, of course, not new. But before Young and Fresnel it cannot be said to have been established.

balance (so to speak) of the composition. Unending space, thinly strewn with suns and satellites, made or in the making, supplied sufficient material for the mechanism of the heavens as conceived by Laplace. Unending space filled with a continuous medium was a very different affair, and gave promise of strange developments. It could not be supposed that the ether, if its reality were once admitted, existed only to convey through interstellar regions the vibrations which happen to stimulate the optic nerve of man. Invented originally to fulfil this function, to this it could never be confined. And accordingly, as everyone now knows, things which, from the point of view of sense perception, are as distinct as light and radiant heat, and things to which sense perception makes no response, like the electric waves of wireless telegraphy,* intrinsically differ, not in kind, but in magnitude alone.

This, however, is not all, nor nearly all. If we jump over the century which separates 1804 from 1904, and attempt to give in outline the world-picture as it now presents itself to some leaders of contemporary speculation we shall find that in the interval it has been modified, not merely by such far-reaching discoveries as the atomic and molecular composition of ordinary matter, the kinetic theory of gases, and the laws of the conservation and dissipation of energy, but by the more and more important part which electricity and the ether occupy in any representation of ultimate physical reality.

Electricity was no more to the natural philosophers in year 1700 than the hidden cause of an insignificant phenomenon.† It was known, and had long been known, that such things as amber and glass could be made to attract light objects brought into their neighbourhood; yet it was about fifty years before the effects of electricity were perceived in the thunderstorm. It was about 100 years before it was detected in the form of a current. It was about 120 years before it was connected with magnetism; about 170 years before it was connected with light and ethereal radiation.

But to-day there are those who regard gross matter, the matter of everyday experience, as the mere appearance of which electricity is the physical basis; who think that the elementary atom of the chemist, itself far beyond the limits of direct perception, is but a connected system of monads or sub-atoms which are not electrified matter, but are electricity itself; that these systems differ in the number of monads which they contain in their arrangement, and in their motion relative to each other and to the ether; that on these differences, and on these differences alone, depend the various qualities of what have hitherto been regarded as indivisible and elementary atoms; and that while in most cases these atomic systems may maintain their equilibrium for periods which, compared with such astronomical processes as the cooling of a sun, may seem almost eternal, they are not less obedient to the law of change than the everlasting heavens themselves.

But if gross matter be a grouping of atoms, and if atoms be systems of electrical monads, what are these electrical monads? It may be that, as Professor Larmor has suggested, they are but a modification of the universal ether, a modification roughly comparable to a knot in a medium which is inextensible, incompressible, and continuous. But whether this final unification be accepted or not, it is certain that these monads cannot be considered apart from the ether. It is on their interaction with the ether that their qualities depend; and without the ether an electric theory of matter is impossible.

Surely we have here a very extraordinary revolution. Two centuries ago electricity seemed but a scientific toy. It is now thought by many to constitute the reality of which matter is but the sensible expression. It is but a century ago that the title of an ether to a place among the constituents of the universe was authentically established.

It seems possible now that it may be the stuff out of which that universe is wholly built. Nor are the collateral inferences associated with this view of the physical world less surprising. It used, for example, to be thought that mass was an original property of matter, neither capable of explanation nor requiring it; in its nature essentially unchangeable, suffering neither augmentation nor diminution under the stress of any forces to which it could be subjected; unalterably attached to, or identified with, each material fragment, howsoever much that fragment might vary in its appearance, its bulk, its chemical, or its physical condition.

But if the new theories be accepted these views must be revised. Mass is not only explicable, it is actually explained. So far from being an attribute of matter considered in itself, it is due, as I have said, to the relation between the electrical monads of which matter is composed and the ether in which they are bathed. So far from being unchangeable, it changes, when moving at very high speeds, with every change in its velocity.

Perhaps, however, the most impressive alteration in our picture of the universe required by these new theories is to be sought in a different direction. We have all, I suppose, been interested in the generally accepted views as to the origin and development of suns with their dependent planetary systems; and the gradual dissipation of the energy which during this process of concentration has largely taken the form of light and radiant heat. Follow out the theory to its obvious conclusions, and it becomes plain that the stars now visibly incandescent are those in mid-journey between the nebulae from which they sprang and the frozen darkness to which they are predestined. What, then, are we to think of the invisible multitude of the heavenly bodies in which this process has been already completed? According to the ordinary view, we should suppose them to be in a state where all possibilities of internal movement were exhausted. At the temperature of interstellar space their constituent elements would be solid and inert; chemical action and molecular movement would be alike impossible, and their exhausted energy could obtain no replenishment unless they were suddenly rejuvenated by some celestial collision, or travel into other regions warmed by newer suns.

This view must, however, be profoundly modified if we accept the electric theory of matter. We can then no longer hold that if the internal energy of a sun were as far as possible converted into heat either by its contraction under the stress of gravitation or by chemical reactions between its elements, or by any other inter-atomic force; and that, were the heat so generated to be dissipated, as in time it must be, through infinite space, its whole energy would be exhausted. On the contrary, the amount thus lost would be absolutely insignificant compared with what remained stored up within the separate atoms. The system in its corporate capacity would become bankrupt—the wealth of its individual constituents would be scarcely diminished. They would lie side by side, without movement, without chemical affinity; yet each one, howsoever inert in its external relations, the theatre of violent motions, and of powerful internal forces.

Or, put the same thought in another form. When the sudden appearance of some new star in the telescopic field gives notice to the astronomer that he, and perhaps, in the whole universe, he alone, is witnessing the conflagration of a world, the tremendous forces by which this far-off tragedy is being accomplished must surely move his awe. Yet not only would the members of each separate atomic system pursue their relative course unchanged, while the atoms themselves were thus riven violently apart in flaming vapour, but the forces by which such a world is shattered are really negligible compared with those by which each atom of it is held together.

In common, therefore, with all other living things, we seem to be practically concerned chiefly with the feeble forces of Nature, and with energy in its least powerful manifestations. Chemical affinity and cohesion are on this

* First known through the theoretical work of Maxwell and the experiments of Herz.

† The modern history of electricity begins with Gilbert, but I have throughout confined my observations to the post-Newtonian period.

theory no more than the slight residual effects of the internal electrical forces which keep the atom in being. Gravitation, though it be the shaping force which concentrates nebulae into organised systems of suns and satellites, is trifling compared with the attractions and repulsions with which we are familiar between electrically charged bodies; while these again sink into insignificance beside the attractions and repulsions between the electric monads themselves. The irregular molecular movements which constitute heat, on which the very possibility of organic life seems absolutely to hang, and in whose transformations applied science is at present so largely concerned, cannot rival the kinetic energy stored within the molecules themselves. This prodigious mechanism seems outside the range of our immediate interests. We live, so to speak, merely on its fringe. It has for us no promise of utilitarian value. It will not drive our mills; we cannot harness it to our trains. Yet not less on that account does it stir the intellectual imagination. The starry heavens have from time immemorial moved the worship or the wonder of mankind. But if the dust beneath our feet be indeed compounded of innumerable systems, whose elements are ever in the most rapid motion, yet retain through uncounted ages their equilibrium unshaken, we can hardly deny that the marvels we directly see are not more worthy of admiration than those which recent discoveries have enabled us dimly to surmise.

Now, whether the main outlines of the world-picture which I have just imperfectly presented to you be destined to survive, or whether in their turn they are to be obliterated by some new drawing on the scientific palimpsest, all will, I think, admit that so bold an attempt to unify physical nature excites feelings of the most acute intellectual gratification. The satisfaction it gives is almost aesthetic in its intensity and quality. We feel the same sort of pleasurable shock as when from the crest of some melancholy pass we first see far below us the sudden glories of plain, river, and mountain. Whether this vehement sentiment in favour of a simple universe has any theoretical justification I will not venture to pronounce. There is no *a priori* reason that I know of for expecting that the material world should be a modification of a single medium, rather than a composite structure built out of sixty or seventy elementary substances, eternal and eternally different. Why, then, should we feel content with the first hypothesis and not with the second? Yet so it is. Men of science have always been restive under the multiplication of entities. They have eagerly noted any sign that the chemical atom was composite, and that the different chemical elements had a common origin. Nor, for my part, do I think such instincts should be ignored. John Mill, if I rightly remember, was contemptuous of those who saw any difficulty in accepting the doctrine of "action at a distance." So far as observation and experiment can tell us, bodies do actually influence each other at a distance. And why should they not? Why seek to go behind experience in obedience to some *a priori* sentiment for which no argument can be adduced? So reasoned Mill, and to his reasoning I have no reply. Nevertheless, we cannot forget that it was to Faraday's obstinate disbelief in "action at a distance" that we owe some of the crucial discoveries on which both our electric industries and the electric theory of matter are ultimately founded; while at this very moment physicists, however baffled in the quest for an explanation of gravity, refuse altogether to content themselves with the belief, so satisfying to Mill, that it is a simple and inexplicable property of masses acting on each other across space.

These obscure intimations about the nature of reality deserve, I think, more attention than has yet been given to them. That they exist is certain; that they modify the indifferent impartiality of pure empiricism can hardly be denied. The common notion that he who would search out the secrets of Nature must humbly wait on experience, obedient to its slightest hint, is but partly true. This may be his ordinary attitude; but now and again it happens that

observation and experiment are not treated as guides to be meekly followed, but as witnesses to be broken down in cross-examination. Their plain message is disbelieved, and the investigating judge does not pause until a confession in harmony with his preconceived ideas has, if possible, been wrung from their reluctant evidence.

This proceeding needs neither explanation nor defence in those cases where there is an apparent contradiction between the utterances of experience in different connections. Such contradictions must of course be reconciled, and science cannot rest until the reconciliation is effected. The difficulty really arises when experience apparently says one thing and scientific instinct persists in saying another. Two such cases I have already mentioned; others will easily be found by those who care to seek. What is the origin of this instinct, and what its value; whether it be a mere prejudice to be brushed aside, or a clue which no wise man would disdain to follow, I cannot now discuss. For other questions there are, not new, yet raised in an acute form by these most modern views of matter, on which I would ask your indulgent attention for yet a few moments.

That these new views diverge violently from those suggested by ordinary observation is plain enough. No scientific education is likely to make us, in our unreflective moments, regard the solid earth on which we stand, or the organised bodies with which our terrestrial fate is so intimately bound up, as consisting wholly of electric monads very sparsely scattered through the spaces which these fragments of matter are, by a violent metaphor, described as "occupying." Not less plain is it that an almost equal divergence is to be found between these new theories and that modification of the common-sense view of matter with which science has in the main been content to work.

What was this modification of common sense? It is roughly indicated by an old philosophic distinction drawn between what were called the "primary" and the "secondary" qualities of matter. The primary qualities, such as shape and mass, were supposed to possess an existence quite independent of the observer; and so far the theory agreed with common sense. The secondary qualities, on the other hand, such as warmth and colour, were thought to have no such independent existence, being, indeed, no more than the results due to the action of the primary qualities on our organs of sense-perception; and here, no doubt, common sense and theory parted company.

You need not fear that I am going to drag you into the controversies with which this theory is historically connected. They have left abiding traces on more than one system of philosophy. They are not yet solved. In the course of them the very possibility of an independent physical universe has seemed to melt away under the solvent powers of critical analysis. But with all this I am not now concerned. I do not propose to ask what proof we have that an external world exists, or how, if it does exist, we are able to obtain cognisance of it. These may be questions very proper to be asked by philosophy; but they are not proper questions to be asked by science. For, logically, they are antecedent to science, and we must reject the sceptical answers to both of them before physical science becomes possible at all. My present purpose requires me to do no more than observe that, be this theory of the primary and secondary qualities of matter good or bad, it is the one on which science has in the main proceeded. It was with matter thus conceived that Newton experimented. To it he applied his laws of motion; of it he predicated universal gravitation. Nor was the case greatly altered when science became as much pre-occupied with the movements of molecules as it was with those of planets. For molecules and atoms, whatever else might be said of them, were at least pieces of matter, and, like other pieces of matter, possessed those "primary" qualities supposed to be characteristic of all matter, whether found in large masses or in small.

But the electric theory which we have been considering

carries us into a new region altogether. It does not confine itself to accounting for the secondary qualities by the primary, or the behaviour of matter in bulk by the behaviour of matter in atoms; it analyses matter, whether molar or molecular, into something which is not matter at all. The atom is now no more than the relatively vast theatre of operations in which minute monads perform their orderly evolutions; while the monads themselves are not regarded as units of matter, but as units of electricity; so that matter is not merely explained, but is explained away.

Now the point to which I desire to call attention is not to be sought in the great divergence between matter as thus conceived by the physicist and matter as the ordinary man supposes himself to know it, between matter as it is perceived and matter as it really is, but to the fact that the first of these two quite inconsistent views is wholly based on the second.

This is surely something of a paradox. We claim to found all our scientific opinions on experience; and the experience on which we found our theories of the physical universe is our *sense-perception* of that universe. That is experience; and in this region of belief there is no other. Yet the conclusions which thus profess to be entirely founded upon experience are to all appearance fundamentally opposed to it; our knowledge of reality is based upon illusion, and the very conceptions we use in describing it to others, or in thinking of it ourselves, are abstracted from anthropomorphic fancies, which science forbids us to believe and Nature compels us to employ.

We here touch the fringe of a series of problems with which inductive logic ought to deal, but which that most unsatisfactory branch of philosophy has systematically ignored. This is no fault of men of science. They are occupied in the task of making discoveries, not in that of analysing the fundamental presuppositions which the very possibility of making discoveries implies. Neither is it the fault of transcendental metaphysicians. Their speculations flourish on a different level of thought; their interest in a philosophy of nature is lukewarm; and howsoever the questions in which they are chiefly concerned be answered, it is by no means certain that the answers will leave the humbler difficulties at which I have hinted either nearer to or further from a solution. But though men of science and idealists stand acquitted, the same can hardly be said of empirical philosophers. So far from solving the problem, they seem scarcely to have understood that there was a problem to be solved. Led astray by a misconception to which I have already referred; believing that science was concerned only with (so-called) "phenomena," that it had done all that it could be asked to do if it accounted for the sequence of our individual sensations, that it was concerned only with the "laws of Nature," and not with the inner character of physical reality; disbelieving, indeed, that any such physical reality does in truth exist;—it has never felt called upon seriously to consider what are the actual methods by which science attains its results, and how those methods are to be justified. If anyone, for example, will take up Mill's logic, with its "sequences and co-existences between phenomena," its "method of difference," its "method of agreement," and the rest; if he will then compare the actual doctrines of science with this version of the mode in which those doctrines have been arrived at,—he will soon be convinced of the exceedingly thin intellectual fare which has been hitherto served out to us under the imposing title of Inductive Theory.

There is an added emphasis given to these reflections by a train of thought which has long interested me, though I acknowledge that it never seems to have interested anyone else. Observe, then, that in order of logic sense-perceptions supply the premisses from which we draw all our knowledge of the physical world. It is they which tell us there is a physical world; it is on their authority that we learn its character. But in order of causation they are effects due (in part) to the constitution of our organs of sense. What we see depends not merely on what there is to be seen, but

on our eyes. What we hear depends not merely on what there is to hear, but on our ears. Now, eyes and ears, and all the mechanism of perception, have, as we know, been evolved in us and our brute progenitors by the slow operation of Natural Selection. And what is true of sense-perception is of course also true of the intellectual powers which enable us to erect upon the frail and narrow platform which sense-perception provides, the proud fabric of the sciences.

Now Natural Selection only works through utility. It encourages aptitudes useful to their possessor or his species in the struggle for existence, and, for a similar reason, it is apt to discourage useless aptitudes, however interesting they may be from other points of view, because, being useless, they are probably burdensome.

But it is certain that our powers of sense-perception and of calculation were fully developed ages before they were effectively employed in searching out the secrets of physical reality—for our discoveries in this field are the triumphs but of yesterday. The blind forces of Natural Selection, which so admirably simulate design when they are providing for a present need, possess no power of prevision, and could never, except by accident, have endowed mankind, while in the making, with a physiological or mental outfit adapted to the higher physical investigations. So far as natural science can tell us, every quality of sense or intellect which does not help us to fight, to eat, and to bring up children, is but a by-product of the qualities which do. Our organs of sense-perception were not given us for purposes of research; nor was it to aid us in meting out the heavens or dividing the atom that our powers of calculation and analysis were evolved from the rudimentary instincts of the animal.

It is presumably due to these circumstances that the beliefs of all mankind about the material surroundings in which it dwells are not only imperfect, but fundamentally wrong. It may seem singular that down to, say, five years ago, our race has, without exception, lived and died in a world of illusions; and that its illusions, or those with which we are here alone concerned, have not been about things remote or abstract, things transcendental or divine, but about what men see and handle, about those "plain matters of fact" among which common sense daily moves with its most confident step and most self-satisfied smile. Presumably, however, this is either because too direct a vision of physical reality was a hindrance, not a help, in the struggle for existence; because falsehood was more useful than truth; or else because with so imperfect a material as living tissue no better results could be attained. But, if this conclusion be accepted, its consequences extend to other organs of knowledge besides those of perception. Not merely the senses, but the intellect, must be judged by it; and it is hard to see why evolution, which has so lamentably failed to produce trustworthy instruments for obtaining the raw material of experience, should be credited with a larger measure of success in its provision of the physiological arrangements which condition reason in its endeavours to turn experience to account.

Considerations like these, unless I have compressed them beyond the limits of intelligibility, do undoubtedly suggest a certain inevitable incoherence in any general scheme of thought which is built out of materials provided by natural science alone. Extend the boundaries of knowledge as you may; draw how you will the picture of the universe; reduce its infinite variety to the modes of a single space-filling ether; retrace its history to the birth of existing atoms; show how under the pressure of gravitation they became concentrated into nebulae, into suns, and all the host of heaven; how, at least in one small planet, they combined to form organic compounds; how organic compounds became living things; how living things, developing along many different lines, gave birth at last to one superior race; how from this race arose, after many ages, a learned handful, who looked round on the world which thus blindly brought them into being, and judged it, and knew it for what it was:—perform, I say, all this, and, though you

may indeed have attained to science, in nowise will you have attained to a self-sufficing system of beliefs. One thing at least will remain, of which this long-drawn sequence of causes and effects gives no satisfying explanation; and that is knowledge itself. Natural science must ever regard knowledge as the product of irrational conditions, for in the last resort it knows no others. It must always regard knowledge as rational, or else science itself disappears. In addition, therefore, to the difficulty of extracting from experience beliefs which experience contradicts, we are confronted with the difficulty of harmonising the pedigree of our beliefs with their title to authority. The more successful we are in explaining their origin, the more doubt we cast on their validity. The more imposing seems the scheme of what we know, the more difficult it is to discover by what ultimate criteria we claim to know it.

Here, however, we touch the frontier beyond which physical science possesses no jurisdiction. If the obscure and difficult region which lies beyond is to be surveyed and made accessible, philosophy, not science, must undertake the task. It is no business of this Society. We meet here to promote the cause of knowledge in one of its great divisions; we shall not help it by confusing the limits which usefully separate one division from another. It may perhaps be thought that I have disregarded my own precept—that I have wilfully overstepped the ample bounds within which the searchers into Nature carry on their labours. If it be so I can only beg your forgiveness. My first desire has been to rouse in those who, like myself, are no specialists in physics, the same absorbing interest which I feel in what is surely the most far-reaching speculation about the physical universe which has ever claimed experimental support; and if in so doing I have been tempted to hint my own personal opinion that as natural science grows it leans more, not less, upon an idealistic interpretation of the universe, even those who least agree may perhaps be prepared to pardon.

ON THE RELATION BETWEEN THE SPECTRA OF SUNSPOTS AND STARS.*

By Sir NORMAN LOCKYER, K.C.B., LL.D., F.R.S.

As the period throughout which the observations of widened lines have been made at South Kensington now includes two maxima and three minima epochs of solar activity, it has seemed desirable to discuss the results obtained, taking into account the chemical origins of the lines affected in passing from the photosphere to the sunspot nuclei. This is going on, but in anticipation of its publication, I desire to direct attention to one of the conclusions arrived at in its bearing upon the question of the temperature conditions of the Arcturian and lower type stars, which formed part of the subject of a recent paper (*Proc. Roy. Soc.*, 1904, vol. lxxiii., pp. 227-238).

Since 1894, when the last discussion of the widened line results was published (*Proc. Roy. Soc.*, 1894, vol. lvii., p. 199), nearly 10,500 observations of lines in sunspot spectra have been made at South Kensington. An analysis of these lines, in respect to their origins, shows that the elements chiefly affected during the period 1892-1903, inclusive, were vanadium and titanium.

The great importance of vanadium and titanium in sunspot spectra has also been demonstrated by Father Corty during his observations in the B-D region at Stonyhurst (*Monthly Notices, R.A.S.*, June, 1903, vol. lxi., No. 8, pp. 479-480).

It was foreshadowed in a previous paper on the chemical classification of the stars (*Proc. Roy. Soc.*, 1899, vol. lxx., p. 191) that it seemed probable that, as the result of further work, the "genera" then proposed might have to be split

up into "species." During the more recent research mentioned above the temperature classification was tested by comparing the relative intensities of the red and ultra-violet ends of the spectra of stars, situated on various horizons of the temperature curve, including Capella and Arcturus, which, according to the original general classification, belong to the same type, viz., "Arcturian." It was found that the spectrum of Capella extended on an average about 70 tenth-metres further into the ultra-violet than that of Arcturus, whilst the red portion of the spectrum is certainly stronger in the latter. That is to say, the general temperature of Arcturus is probably appreciably lower than that of Capella.

The next step was to see if chemical change accompanied this reduction of temperature, and if so, whether the change was in any way related to the change from the photosphere to the sunspot spectrum.

In comparing, for this purpose, the spectra taken with a 6-inch Henry prismatic camera it was noticed that certain lines were relatively intensified in passing from the spectrum of Capella to that of Arcturus.

Similar comparisons of the Fraunhofer spectrum with the spectra of Capella and Arcturus respectively were next made. This worked led to the following conclusions:—(1) That the line absorptions of Capella and the sun are practically identical; (2) that although, speaking generally, the same lines occur in the spectra of the sun and Arcturus, yet in the latter many lines are relatively more intense than in the former. Moreover, in the great majority of such cases the lines so intensified are probably due to vanadium and titanium.

Thus we see that whilst the temperature classification mentioned above certainly places Arcturus on a lower temperature level than Capella, and therefore the sun, the evidence obtained from a study of the line absorptions of Arcturus and of sunspots indicates very clearly that the temperature of the Arcturian absorbing atmosphere is about the same as that of the sunspot nuclei during the above-mentioned period.

This conclusion justifies the ideas formulated by De la Rue, Stewart, and Loewy, that the spots are produced by the downrush of cooler material.

In a recent publication ("The Spectra of Stars of Secchi's Fourth Type," "The Decennial Publications," Chicago University, 1903), which has been received here since the above-mentioned comparisons were completed, Professor Hale suggests that because the lines which are widened in sunspots appear as strong dark lines in Piscian stars, the effect may be produced because sunspots are more numerous in such stars. From the evidence adduced above it seems a far more probable explanation to suppose that these lines are intensified in sunspots, and strengthened in those stars which have been placed on lower temperature levels than the sun, because the general temperature conditions are similar. That is to say, the fall of temperature experienced by the metallic vapours in passing from the photosphere to the spot nucleus is of the same order as that to which an absorbing atmosphere is subjected in passing from the temperature conditions of Capella or the sun to that of Arcturus or the lower temperature stars.

Determination of Palladium.—H. Erdmann and O. Makowka.—The use of acetylene for the determination of palladium and its separation from other metals offers many advantages over that of hydrazine, as described by Jannasch recently. By means of this reagent palladium is readily separated from platinum, iridium, rhodium, and gold. For, by addition of acetylene either in aqueous solution or as a gas to the strongly acid solution in the cold, the palladium separates out in the form of a yellowish brown precipitate readily soluble in ammonia. This precipitate is not explosive, and on ignition with a small quantity of ammonium nitrate in a current of hydrogen readily yields the pure metal. The presence of copper does not hinder the reaction, as is the case when hydrazine is used.—*Berichte*, xxxvii., No. 11.

THE
SEPARATION OF THE MOST VOLATILE GASES
FROM AIR WITHOUT LIQUEFACTION.*

By Sir JAMES DEWAR, M.A., D.Sc., LL.D., F.R.S.,
Jacksonian Professor, University of Cambridge, and
Fullerian, Royal Institution, London.

FROM the time when liquid air came to be an ordinary laboratory agent I have continually used it for the purpose of producing high vacua in vessels that had been previously filled with easily condensable gases, like sulphurous acid, carbonic acid, vapour of water, or benzol.

When the liquefaction of hydrogen was effected, one of the first scientific uses to which it was put was that described in my paper on the "Application of Liquid Hydrogen to the Production of High Vacua, together with their Spectroscopic Examination" (*Proc. Roy. Soc.*, 1898, vol. lxiv.; *CHEMICAL NEWS*, vol. lxxix., p. 73). In that communication it was shown by theory and confirmed by experiment that the condensing power of liquid hydrogen is so great relatively to that of liquid oxygen or nitrogen, that any closed vessel a part of which is cooled to the boiling-point of hydrogen must suddenly become a highly vacuous space. This was proved by the great difficulty of getting electric discharges to pass through specially prepared spectroscopic tubes when subjected to liquid hydrogen cooling, and from the fact that when the current did pass no lines of oxygen or nitrogen were seen, but only those of hydrogen, helium, and neon. In order to separate these latter gases from air, it was necessary to liquefy a quantity of air and to distil off the most volatile portion at as low a temperature as possible into a separate receiver placed in liquid hydrogen. In this way many spectroscopic tubes were filled with the uncondensable air gases, and the results of their examination is recorded in a paper entitled "On the Spectra of the More Volatile Gases of Atmospheric Air, which are not Condensed at the Temperature of Liquid Hydrogen," by Professor Liveing and myself (*Proc. Roy. Soc.*, 1900, vol. lxxvii.; *CHEMICAL NEWS*, vol. lxxxiii., p. 1).

Some two years later I improved the method of separation of the volatile air gases. The process is fully described and illustrated in my paper on "Problems of the Atmosphere" (*Proc. Roy. Inst.*, 1902). Its success depends upon the continuous direct liquefaction of air at atmospheric pressure combined with a device which enables the more volatile gases to be trapped and separated. In this way some 1/35,000th of the volume of the air liquefied is collected as a gaseous mixture having the composition 38 per cent of nitrogen, 4 per cent of hydrogen, and 58 per cent of mixed helium and neon. After sparking to remove the nitrogen and hydrogen, a gaseous mixture of helium and neon, containing a little argon, was obtained. This mixture had the composition of 16 per cent helium and 84 per cent neon. In both methods of treatment it will be noted the liquefaction of the air was the essential preliminary operation, to be supplemented in the one case by the use of liquid hydrogen, in the other by sparking to remove the nitrogen. The paper already communicated to the Royal Society, entitled "The Absorption and Thermal Evolution of Gases Occluded in Charcoal at Low Temperatures," in which the greatly increased power of occlusion possessed by charcoal at low temperatures is proved, suggested an inquiry into the limits of gaseous pressure reached by such means of condensation. (See *CHEMICAL NEWS*, vol. xc., p. 73).

With this object a narrow tube *CE*, Fig. 1, was sealed to an ordinary spectroscopic sparking tube *AB*, at the end

E an enlarged space was blown out capable of holding a few grammes of coconut charcoal. After the charcoal had been freed from gases by heating and exhaustion, and the poles cleared by sparking during this operation, pure and dry gases like oxygen, nitrogen, air, carbonic oxide, hydrogen, neon, and helium could be admitted at different pressures, and the tube with its charcoal chamber attached sealed off.

On placing the charcoal end of the apparatus in liquid air the gas in each case was rapidly absorbed, and the vacuum produced reached the phosphorescent stage in all cases with the exception of hydrogen, neon, and helium. A small Crookes's radiometer, full of air at atmospheric pressure, with charcoal tube attached, became quite active to heat radiation when the charcoal was cooled for half a minute in liquid air. To test the amount of exhaustion reached by the use of a given weight of coconut charcoal, I sealed on a tube containing 30 grms. to a large electric discharge tube of 1300 c.c. capacity filled with air at atmospheric pressure. On cooling the charcoal receptacle in liquid air the pressure diminished to 50 m.m. of mercury. Repeating the same experiment, but starting with the tube initially at half an atmosphere, the exhaustion reached was now beyond the striæ stage. A further experiment, starting with one-fourth of an atmosphere, gave a vacuum through which no discharge passed.

Finally, the 30 grms. of charcoal were replaced by only 1 grm., and the initial pressure was reduced to 3 m.m. of mercury. Now the vacuum just reached the beginning of the phosphorescent stage. With hydrogen, either a pressure of gas less than that of the atmosphere had to be used at starting, or a larger amount of charcoal employed in order to get a vacuum well up in the striæ stage. If, however, the liquid air was cooled to -210°C . by exhaustion, the tube just reached the beginning of phosphorescence round the cathodes.

With helium there was a very slight absorption, but neon did show something more appreciably. Spectroscopic observations made during the condensation of the gas in the charcoal showed the gradual disappearance of the characteristic spectrum of oxygen, nitrogen, and air, as the high vacuum was reached and the discharge passed with great difficulty. In tubes of this kind filled at atmospheric pressure I could always see the F line of hydrogen and the neon yellow; but the helium was not seen with any definiteness. As the amount of neon in the air cannot well exceed 1/50,000th, the spectroscopic test is very delicate.

In order to bring in the helium lines it was necessary to concentrate the volume of air in the space of the sparking tube six or seven times. This was done by the use of an arrangement shown in Fig. 2. *AB* is the sparking tube with its small charcoal bulb *C* attached, capable of being sealed off when required at *G*; and *D* and *E* are larger charcoal absorbers placed in vacuum tubes containing liquid air; the whole being attached to a graduated gas-holder containing air. A series of glass stopcocks are attached at the points *h*, *i*, *j*, and *k* in order to facilitate manipulation. In determining the volume of air required to bring in the helium lines, only one charcoal absorber containing about 15 grms. of material was used. On allowing 200 c.c. of air from the gas-holder to be sucked into the charcoal (which had been previously exhausted along with the sparking tube), on opening the stopcock *h* any residuary gas in *D* was swept into the sparking tube, which was then sealed off at *G*.

This tube gave the hydrogen lines *C* and *F*, the neon yellow, and some of the orange lines, along with the helium yellow and green, quite distinct. With the residuary gas extracted from 1 litre of air I could see all the helium lines. On the positive pole the neon yellow and the green of helium were alone marked, while the negative pole gave both the neon and helium yellow lines along with the helium green and the F of hydrogen on the continuous spectrum. From this it would appear that the spectroscopic test for helium is as delicate as that for neon, and that

FIG. 1.

* A Paper read before the Royal Society, June 16, 1904.

1/50,000th can be recognised. From 3 litres of air discharge tubes were obtained, giving the neon and helium spectra associated with a brilliant ruddy glow discharge.

efficient assistance in the conduct of the experiments, and Mr. J. W. Heath, F.C.S., has also helped me in the investigation.

FIG. 2.

As 40–50 grms. of charcoal can absorb at the temperature of liquid air from 5–6 litres, it is easy to accumulate rapidly the uncondensed gases in considerable quantities for spectroscopic examination. For this purpose I found it convenient to use two charcoal condensers in circuit, as represented in Fig. 2. After the charcoal in the first one marked E was saturated, the stopcock K was closed, while I and J were opened for a short time, so as to allow the less condensable gas in E to be sucked into the second vessel of the same type D along with some portion of air. The charcoal condenser E was then taken out of the liquid air, and rapidly heated to 15° C. in order to expel the occluded air. It was thus in a condition to repeat the absorption. In this way 50 litres of air can be treated in a short time. Sparking tubes filled from the accumulated gases in D were very brilliant, showing the complete spectrum of the volatile constituents of air. It is hardly necessary to remark that after the little charcoal receptacle connected to each of the sparking tubes had been cooled, and thus all traces of air absorbed, it can be sealed off, leaving the spectroscopic tubes intact. The complete spectroscopic study of the products must be left for further examination with Professor Living.

The method I have described will be equally applicable to the treatment of the gaseous products from minerals containing helium, hydrogen, &c., and also to the radium products of a similar kind. It seems even probable that the separation of the less volatile constituents in air may be improved by a slight modification in the mode of working. The behaviour of the gases from the Bath Springs has been examined. When the gas containing 1/1000th part of helium in what may be regarded as pure nitrogen is subjected to charcoal absorption exactly in the same way as the air was treated, no high vacuum is reached. All the nitrogen and any other constituents disappear, and a spectrum of helium and hydrogen showing much less neon than exists in the volatile residue from atmospheric air is the result. A sample of argon made from Bath gas gave, when the argon was absorbed in charcoal, a gas residuum giving the helium and neon spectrum, and the same result follows the use of atmospheric argon. In the case, however, of the Bath gas argon the helium spectrum is the stronger, whereas with air argon the neon is the most pronounced.

In order to further test the method, the crude gases got by heating the mineral Fergussonite were examined. During the cooling of the charcoal the nitrogen and hydrogen spectra were marked, but in a short time nothing could be seen but the lines of hydrogen and helium.

Great interest will attach to the behaviour of helium, hydrogen, and the most volatile part of air when subjected to the action of charcoal cooled to the temperature of liquid hydrogen. The method promises to open up many avenues for future inquiry.

I am indebted to Mr. Robert Lennox, F.C.S., for

THE USE OF TETROXALATE OF POTASSIUM IN TITRATION.

IN 1856, Krant proposed using tetroxalate of potassium for titrations, but the proposition was received with very varying opinions on the part of analytical chemists. Some looked upon the tetroxalate as a substance which could be obtained easily as a definite chemical compound; that is to say, in a pure state and of constant weight; others, on the other hand, did not admit this characteristic, and did not consider that it was suitable for making titrations. More especially Meinecke's assertion was rejected as incorrect, according to which tetroxalate of potassium dried for some weeks over concentrated sulphuric acid, could be obtained pure and would have the following composition:— $C_2O_4.HK + C_2O_4.H_2 + 2H_2O$.

According to a paper of O. Kuhling's (*Zeit. f. Ang. Chem.*, 1903, p. 1030), he has succeeded in preparing this salt in the pure state. He proposes to use the following method:—

By Cl. Winkler's method, commercial oxalic acid is crystallised twice in warm hydrochloric acid of 1.07 density, and three times in boiling distilled water. The product obtained should not contain any of the halogen elements, and should not leave any residue on calcination. It is placed in a quantity of water insufficient to dissolve it for twenty-four to forty-eight hours. It is then transferred to a glass flask and shaken frequently. A quarter of this cold saturated solution is taken and treated according to Meinecke's method with a few drops of phenolphthalein, and, while stirring, a solution of potassic hydrate, freshly prepared and crystallised in alcohol, is poured in up to the moment when a persistent red colouration appears. The neutralised solution is then treated with the remaining three-quarters of the tetroxalate solution, the sides of the glass are rubbed with a glass stirring rod, and soon we observe the formation of a crystalline deposit of tetroxalate of potassium. To obtain the best results it is necessary to re-dissolve the crystals first formed in the mother-liquor by heating it to the required temperature; the vessel is then placed in cold water, and the sides of the glass again rubbed with a glass rod to effect the re-crystallisation of the tetroxalate. To have a perfectly pure salt, the powder obtained is drained on a hard filter, re-dissolved, and re-crystallised two or three times, treating it with smaller and smaller quantities of boiling distilled water, and cooling rapidly after each heating. The product, drained as before, and protected from the action of dust, is dried between sheets of filter-paper until a small portion pressed against the surface of a dry glass does not show any trace of moisture; this generally takes about two days. The salt is then kept in well-stoppered bottles.

From the numerous experiments made by the author and the values he has obtained in the titrations effected, he

attributes the following formula to the salt prepared by the above method: $\text{—C}_2\text{O}_4\text{HK} + \text{C}_2\text{O}_4\text{H}_2 + 2\text{H}_2\text{O}$.

The author also finds that this salt keeps very well.—*Pharmac. Centralblatt.*, vol. xlv., p. 915.

RADIO-ACTIVE LEAD, RADIO-TELLURIUM, AND POLONIUM.

By A. DEBIERNE.

POLONIUM, which was first discovered by M. and Mme. Curie, has the following characteristic properties:—Its solutions are precipitated by hydrogen sulphide in presence of an acid, and it resembles bismuth in various chemical reactions. Its radiation is distinct from that of uranium, thorium, radium, and actinium, and consists entirely of the almost non-penetrating α -rays, which are only slightly affected by a magnet. Polonium gives out no emanations, and does not induce radio-activity.

Two other radio-active substances, which are also precipitated by hydrogen sulphide, have been found in pitchblende. MM. Hofmann and Strauss first called attention to a chemically active substance analogous to lead, which is known as radio-active lead, whilst M. Marckwald published several papers dealing with another active body known as radio-tellurium, which is obtained with polonium and retained by tellurium in several reactions. Mme. Curie and M. Giesel question the existence of this latter body, which they consider to be identical with polonium.

Having at my disposal a large quantity of the residues left from the extraction of radium, I tried to obtain MM. Hofmann and Strauss' substance. The lead contained in these residues was first dissolved in strong soda solution, then precipitated by sodium sulphide in the form of sulphide. The sulphides were then transformed into nitrates, evaporated to dryness, and re-dissolved in water, and purified as completely as possible by a number of crystallisations from water.

These nitrates had a very slight radio-activity, only twice that of uranium. By force of circumstances these were kept for three years before being worked again, and during this period the radio-activity remained constant. Various efforts to concentrate the activity by fractional crystallisation were made on the radio-active lead thus obtained.

The crystallisation of the nitrates is of very little use, that of the chloride or the acetate giving decidedly better results. However, the most advantageous method consists in adding a large excess of hydrochloric acid to a hot concentrated solution of the nitrate. Under these conditions a large proportion of the lead chloride precipitates or crystallises out on cooling, and nearly all the radio-activity remains in the solution. This solution is concentrated and more hydrochloric acid added, whereby more lead chloride is deposited. By repeating these operations several times the non-active lead chloride can be eliminated, and the greater part of the activity can be concentrated in a small quantity of matter. This portion, which contains chiefly lead, is purified from small traces of copper and iron, and then transformed into nitrate. The solution is next concentrated, made slightly acid, and added to a large quantity of water. A very slight precipitate of basic bismuth nitrate is formed.

This precipitate contains nearly all the radio-activity, and possesses all the characteristics of poloniferous bismuth. Its activity is extremely great; it has not been measured exactly, but is certainly more than 100,000 times as great as that of uranium. The radiation has similar properties to that of polonium; it forms a homogenous pencil of almost non-penetrating rays, which are only slightly affected by the magnetic field. The active matter thus obtained also shows all the properties of the radio-tellurium of M. Marckwald. It gives with stannous chloride a slight very active precipitate, and a thin piece of bismuth plunged in a hydrochloric solution of this substance

becomes covered with a slight deposit of extremely radio-active matter.

It is thus seen that the same radio-active substance shows successively properties characteristic of radio-active lead, polonium, and radio-tellurium. The apparent conclusion to be drawn is that there is no distinction between these three bodies, and that in pitchblende there only exists a single radio-active substance which is precipitated by sulphuretted hydrogen in acid solution. The name polonium should naturally be the one retained, as that was originally given by M. and Mme. Curie.

We can also conclude from the above experiments that a radio-active substance cannot be identified by chemical reactions, and on account of the very small quantities contained in minerals, analytical separations merely cause this substance to be shared amongst the different fractions.

One test only can be employed with certainty, and this is the nature of the radio-activity and the identity of the radiation emitted by polonium, radio-tellurium, and radio-active lead would in itself predict the results obtained above.

I will conclude this paper by drawing attention to the fact that the radio-active lead nitrate which was used in these researches has absolutely retained its activity for several years, although it was so feeble; whilst in the specimens of polonium obtained during the first experiments this activity gradually disappeared. The constancy of the activity must then depend on external conditions which it will be very important to determine. It is possible that under certain conditions the activity of other substances, such as uranium, thorium, radium, and actinium, will diminish and disappear in the same manner as that of polonium.—*Comptes Rendus*, vol. cxxxix., No. 4, p. 283.

PRELIMINARY NOTES UPON SANSEVIERA THYRSIFLORA.

By FREDERICK DAVIS.

The plant *Sansevieria thyrsiflora*, indigenous to South Africa, belongs to the natural order *Liliaceae*, and is largely used in its fresh state as a remedy for piles. Many other species of the same family, such as *Sansevieria zeylanica*, are the source of a very strong and tough fibre known commercially as "bow-string hemp." It was noticed during the African campaign that Boers suffering from hemorrhoids dug up a portion of the rhizome, freed it from extraneous matter, trimmed off the outer integuments, and chewed the inner portion, swallowed the extractives, and rejected the fibres which remained as a tangled mass in the mouth after chewing.

Captain Tremlett observing this ascertained that in each case a cure was effected, and desiring to know more of the remedy a quantity of the rhizome was sent to an English consulting physician, who directed me to ascertain the best methods of preserving the extractives without impairing the physiological action, and if possible determine the active constituents.

There is practically no literature upon the subject, but I notice in Prof. Andrew Smith's "Contributions to the South African Materia Medica" the following remarks:—"This plant is to be seen frequently beneath trees and in thickets, with its sword-shaped leathery leaves with a border and zig-zag white markings. Its root is given by Dr. Pappe as used for piles. The Kaffirs employ a decoction of the root-stock to expel all kinds of worms. An experienced native declares it to be very efficacious."

The plant is known in Africa as Sikolakota, and by the Kaffirs as "Isi kolakota."

My researches seem to prove the rhizome contains:—

1. A glucoside.
2. A globulin.
3. An albumen.

The globulin and the albumen reside principally in the plexm of the fibro-vascular bundles, whilst the glucoside is found chiefly in the inner portion of the outer integument and the ground tissue; it will be imperative, therefore, in making any extract or other preparation from this plant that the whole rhizome be employed, or the entire medicinal constituents will not be obtained.

Secondly, I am of opinion that any medicinal preparation of this plant should be made from the fresh rhizome, because, if partially dried, fermentation would be set up, with the consequent decomposition of the active principles, and its efficacy as a medicament would be destroyed, whilst the entirely dried rhizome, although free from the objection of enzymotic change, is found to be less active for the purpose for which it is intended, and in addition, if not dried quickly and at a low temperature, its colour suffers markedly.

The best preparation pharmaceutically, and most active physiologically, has been made by the following simple method:—

Press out the juice from the fresh rhizome, filter, and preserve by the addition of 20 per cent of glycerin.

The addition of ethylic alcohol impairs the physiological action.

The character of the glucoside found somewhat resembles that of glycyrrhizin; from ultimate analysis it is probably identical, $C_{44}H_{63}NO_{18}$.

The substance is optically inactive, and several separately obtained samples varied in melting-point between 178° and 200° .

It must be distinctly understood the above preliminary statement does not profess to be the exhaustive results, as indications have already been obtained of the presence of another important constituent.

NOTES ON THE SOFTENING OF HARD WATER.

By NICHOLAS KNIGHT.

THE work was done in the Chemical Laboratory of Cornell College by C. G. Eldredge.

A water, which is probably a fair type of the various supplies in the dolomite region of the Mississippi Valley, was studied with a view to rendering it more soft for domestic and boiler purposes. The water supply of Mount Vernon, in Eastern Iowa, was examined. The water is pumped from a well 330 feet in depth, of which 315 feet is in the Niagara magnesian limestone. The substances, therefore, which cause the hardness are calcium and magnesium carbonates, with a small amount of calcium sulphate.

The total amount of the solids in the water was obtained by evaporating 500 c.c. to dryness in a weighed platinum evaporating dish of 150 c.c. capacity, and afterwards drying in an air-bath at 110° to constant weight. From this the silica, iron and alumina, calcium and magnesium were determined. The amounts of sulphates and alkaline chlorides were estimated from other portions of water. On account of a possible variation in the quantity of dissolved substances in such waters, the entire amount required for these experiments was taken at the same time and kept in a cool place in glass-stoppered bottles. The numbers given express the amounts of the various substances in 100,000 parts of the water.

1. Total solids in platinum dish	28.86
$CaCO_3$	12.47
$MgCO_3$	10.42
$CaSO_4$	0.989
SiO_2	2.12
Fe_2O_3 and Al_2O_3	0.266
NaCl and KCl	2.34
	28.60

A. The Effect of Boiling on Precipitating the Calcium and Magnesium Carbonates.

2. Five hundred c.c. of the water was placed in a litre flask of Jena glass, heated to boiling with a triple burner, and boiled vigorously for two minutes. Ten c.c. of the water evaporated by the boiling. The flask was allowed to cool, the contents were filtered, and the filtrate evaporated to dryness in the platinum dish, and treated in every respect like the unboiled specimen. The amounts obtained were as follows:—

Total solids in platinum dish	23.38
$CaCO_3$	9.27
$MgCO_3$	9.53
$CaSO_4$	0.98
SiO_2	1.68
Fe_2O_3 and Al_2O_3	0.25
NaCl and KCl	2.34
	24.05

The difference between the results here obtained and in No. 1 is due chiefly to the precipitation of calcium carbonate. The magnesium suffered a comparatively slight change. The boiling water in this and subsequent experiments did not seem to dissolve the glass, as shown by the amount of silica obtained.

3. Five hundred c.c. of the water was heated to boiling in the flask, and the boiling was vigorously continued for ten minutes. Forty-five c.c. of the water evaporated during the time. The total solids obtained in the platinum dish = 20.00.

$CaCO_3$	4.92
$MgCO_3$	9.75
$CaSO_4$	0.98
SiO_2	1.78
Fe_2O_3 and Al_2O_3	0.32
NaCl and KCl	2.34
	20.09

4. Five hundred c.c. boiled for twenty minutes in the same flask; 70 c.c. evaporated. The filtered residue, evaporated to dryness in the platinum dish, gave as the total solids 19.18.

$CaCO_3$	4.25
$MgCO_3$	8.52
$CaSO_4$	0.98
SiO_2	1.66
Fe_2O_3 and Al_2O_3	0.27
NaCl and KCl	2.34
	18.62

Boiling twenty minutes removes about 66 per cent of the calcium carbonate and 18 per cent of the magnesium carbonate—about 44 per cent of the temporary hardness. It should also be noted that where the hardness is more largely due to calcium and magnesium sulphates, with smaller amounts of the carbonates, boiling to remove the carbonates would tend to increase the concentration of the solution of sulphates, and therefore the hardness of the water, instead of diminishing, might be increased.

B. The Effect of Lime-water on the Calcium and Magnesium Carbonates.

Three hundred c.c. of the water was shaken in a flask with 150 c.c. of lime-water. The mixture was allowed to stand twenty-four hours, when it was filtered and evaporated to dryness. The total solids were found to be 15.10.

All of the magnesium carbonate was removed, but an excess of calcium oxide from the lime-water remained. The experiment was repeated a number of times to find the minimum of lime-water that would leave the smallest quantity of total solids. The lime-water was prepared from distilled water. The following proportions were used:—

112½ c.c. of lime-water to 300 c.c. of the water.

75	"	"	"
100	"	"	"
37½	"	"	"
90	"	"	"
30	"	"	"
22½	"	"	"

In each case the total solids obtained were comparatively large, either from the excess of lime-water used or because the amount of lime-water was insufficient to remove the carbonates to any extent. The experiments were repeated with baryta-water, but the results were also unsatisfactory. In a number of trials it was sought to remove the excess of lime by acidifying the mixture with a stream of carbon dioxide. On evaporation the carbon dioxide would escape, and the solution would again react alkaline. In other cases the mixture of the water and lime-water was allowed to stand in a shallow dish exposed to the air for a number of days, and then filtered and evaporated. No attempt was made to remove the excess of calcium oxide with sodium carbonate.

A more satisfactory result was obtained by taking 300 c.c. of the water, and using two or three drops of a tenth normal solution of silver nitrate as an indicator. The lime-water was dropped from a burette until the mixture showed an alkaline reaction. Fifty c.c. of lime-water was required.

Total solids	15.14
CaCO ₃	5.21
MgCO ₃	4.23
CaSO ₄	0.98
SiO ₂	2.12
Fe ₂ O ₃ and Al ₂ O ₃	0.26
NaCl and KCl	2.34
	15.14

The experiment was repeated, using as an indicator two or three drops of phenolphthalein solution made by dissolving 1 gm. of the powder in 200 c.c. of 95 per cent alcohol. Fifty c.c. of lime-water was again required. The result is as follows:—

CaCO ₃	2.41
MgCO ₃	4.13
CaSO ₄	0.98
SiO ₂	2.12
Fe ₂ O ₃ and Al ₂ O ₃	0.26
NaCl and KCl	2.34

12.24

The best results seem to come from adding the lime-water to the water in the ratio of one to six. The lime-water can be tasted in the mixture, which is quite unfit for drinking purposes. This of course would not be an objection for boiler use.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

Berichte der Deutschen Chemischen Gesellschaft.
Vol. xxxvii., No. 11, 1904.

Atomic Weight of Iodine.—P. Köthner and E. Aeuer.

—Two years ago Ladenberg described a new method of preparing pure iodine, depending upon the different solubilities of the silver haloid salts in ammonia; and with the iodine thus obtained he carried out atomic weight determinations, finding, as the mean of three experiments, $I = 126.960$ ($O = 16$). The value found by Stas, using three different methods, is 126.85, and both these numbers have been confirmed by other observers—the one by Scott, and he other by Marignac. The authors undertook a particularly exhaustive and careful research to explain this

difference and establish the true atomic weight. They found that Ladenburg's method, resting on the determination of the ratio of AgI to $AgCl$ by decomposition of AgI in a current of chlorine, was liable to error, but not sufficient to account for the difference between his and Stas' number. Using the same method, and taking all precautions, they found, as the mean of eight experiments, that the atomic weight is 126.936. However, using a different specimen of silver iodide, which was as pure as Stas' preparation, they obtained a value practically identical with his. Hence they concluded that the treatment of silver iodide with ammonia really purified it, and elaborated another method of obtaining perfectly pure iodine, viz., the distillation of ethyl iodide, which boils at 72°, while ethyl chloride boils at 12°, and the bromide at 38°. The pure ethyl iodide was carefully fractionated, and the hydrogen iodide obtained from it was precipitated with a weighed quantity of silver. This synthesis gave $I = 125.978$. Finally, they synthesised silver iodide by igniting silver in a current of iodine—a method which undoubtedly gives the lowest limit of the atomic weight. This gave 126.963 (vacuum). Thus the authors believe that they may safely say definitely that the atomic weight of iodine is not less than 126.963.

Solubility of Silicon in Silver, and a Modification of Silicon Soluble in Hydrofluoric Acid.—H. Moissan and F. Siemens.—Silicon is much more soluble in silver than in lead or zinc, and begins to dissolve at 960°. On allowing the silicon to crystallise out from the solution, part of it is found to differ from other forms of silicon in that it is soluble in hydrofluoric acid. The solubility of silicon in silver rises decidedly with the temperature, and the percentage of silicon soluble in hydrofluoric acid decreases as the total amount of silicon dissolved increases. Moreover, it was found that more of the soluble silicon dissolves if the silver is not saturated with silicon, and if only 2 per cent of silicon is contained in the silver, practically all the silicon which crystallises out is soluble in hydrogen fluoride. The crystals of this new modification of silicon are mostly thin, yellow, transparent scales, their size depending on the rate of crystallisation. Their density in water and benzene very nearly approximates to that of the other forms of silicon. When heated to 1200° in a current of hydrogen or nitrogen, this modification still retains its solubility in hydrofluoric acid. Careful analysis proved the absence in it of all impurities except traces of iron and microscopic crystals of carborundum. It is to be noted that the preparation of this modification must be performed in a reducing atmosphere, since otherwise the silver absorbs the oxygen present, which then oxidises a portion of the silicon, and thus a mixture of silicon and silica is obtained.

Products of Decomposition of Brom-succinic Acid and its Salts in Aqueous Solution.—Wolf Johannes Müller and F. Suckert.—On heating dilute solutions of brom-succinic acid malic acid is chiefly formed, while in concentrated solutions fumaric acid is the principal product. Fumaric and malic acids only differ from one another by one molecule of water. The authors found that by titrating a completely decomposed solution of brom-succinic acid the total amount of organic acids was given, which could be calculated to fumaric salt. On evaporating the solution and weighing the residue the actual quantity of salt was obtained, the difference giving the extra water which the malic acid contains, from which the amount of malic acid can be calculated. Applying this method at different temperatures, they found that the amount of fumaric acid formed is proportional to the concentration of the brom succinic acid raised to the power 3/2, and that raising the temperature increases the formation of fumaric acid. On the other hand, salts of brom-succinic acid give rise to pure malic acid only, no trace of fumaric acid being formed. The addition of hydrochloric acid increases the proportion of fumaric acid, independently of the temperature, and this increase is greater in dilute than in concentrated solutions of brom-succinic acid.

Fluorescence.—Hugo Kauffmann and Alfred Beisswenger.—3-Aminophthalimide shows a green fluorescence and yellow colour in dissociating media, such as water and alcohol, and a violet fluorescence and a paler yellow colour in benzene and ligroin and other non-dissociating media. This change in colour and fluorescence in different solvents has been supposed to be due to tautomerism. Further research, however, has shown that it is due to changes in the benzene ring. The authors have now proved that (1) the change of fluorescence is by no means limited to 3-aminophthalimide and its derivatives, but is a general property of fluorescing amines. Moreover, the change in colour is a property of non-fluorescing amines. Temperature has some influence on fluorescence and colour; for example, a solution of acridone in pyridine has in the cold a violet fluorescence, which almost completely disappears on heating; (2) the fluorescence and colour changes cannot be due to tautomerism, for the introduction of amyl and alkyl groups, *i.e.*, the prevention of the possibility of such tautomerism, does not abolish the change of fluorescence; (3) the molecular weights of some amines were determined in benzene by the cryoscopic method, and it was shown that the molecular weight in non-dissociating solvents is the simplest. By their experiments the authors have proved that the changes do not depend upon a change of molecular weight. There was still the possibility that compounds were formed between the dissolved substance and the solvent. But such compounds can hardly be concerned in the fluorescence and colour changes, as both strongly and feebly basic amines, which, moreover, can be formed from most different classes of compounds, behave in exactly the same manner.

Proof of Racemic Character.—E. Mohr.—According to theory, the reaction—

should give a mixture of two structurally identical stereoisomeric racemic acid amides; and this reaction could, under suitable conditions, be applied to determine whether an amide or acid chloride is racemic or not. The author has examined the case of the following reaction:—

and found that the product could be very readily split into two constituents by systematic crystallisation from boiling petroleum ether; these two substances melted at 112° and 85°—87° respectively, and analysis showed that their formula was C₁₉H₂₃ON. Thus, by means of this reaction (or a similar one), it can be experimentally determined whether a substance is a racemic compound (or an inactive mixture) or not, without actually decomposing it into its two optically active components (or isolating one of them), and without the aid of optically active substances. Van't Hoff has already suggested a method for proving the racemic nature of a compound without directly splitting it up, but he employed an optically active substance.

Decomposition of Paracautchouc by means of Ozone.—C. Harries.—Paracautchouc is remarkably stable towards permanganate. The author has shown by a number of experiments that unsaturated compounds, when treated with ozone, can attack the molecule O₃ at each double bond. The resulting explosive ozonides are decomposed on warming with water into aldehydes or ketones and hydrogen peroxide. Pure paracautchouc is attacked much less easily than the vulcanised substance, but if the caoutchouc is dissolved in chloroform and then treated with ozone, on removal of the chloroform a colourless syrup remains (*viscous*) which behaves like an ozonide. It may be purified by dissolving in acetic ether and precipitating with petroleum ether. Analysis of the purified substance points to the formula C₁₀H₁₆O₆. The molecular

weight is about 526, but the ozonide thus prepared still contains some chlorine, owing to the difficulty of completely removing the chloroform. When boiled with water for a short time the aqueous solution gives the very characteristic reactions of the keto- and di-aldehydes, laevulinic aldehyde, and succinic aldehyde. If the boiling with water is allowed to proceed for a longer time, the hydrogen peroxide evolved oxidises the aldehyde first formed to the corresponding acids, laevulinic acid and a small quantity of an acid allied to, but not identical with succinic acid. The formation of laevulinic acid shows that the simple molecule C₁₀H₁₆ must contain the complex radical $\begin{array}{c} \text{C} \\ \text{C} \end{array} > \text{C}:\text{CH}.\text{CH}_2.\text{CH}_2.\text{C}:\text{CH}.\text{C}$. It is noteworthy

that no trace of oxalic acid results, while oxidation of caoutchouc and its derivatives by other means produces large quantities of it. The ozonides possess the property of emitting rays which appear to act on the photographic plate much more strongly than ozone; this property is possessed in a high degree by the caoutchouc ozonide here described.

Chromates of the Polyatomic Metals.—O. Meyer.—*Chromates of Silver.*—The precipitation of a solution of NO₃Ag by means of Cr₂O₇K₂ with or without the addition of an excess of nitric acid, always gives the dichromate, Cr₂O₇Ag₂, a ruby-red powder which dissolves when heated in the presence of an excess of nitric acid, and re-crystallises on cooling into very fine plates resembling iodine. The trichromate is never obtained. The dichromate is soluble in the cold in 12,000 parts of water. *Dichromate of Barium.*—This salt, Cr₂O₇Ba, forms in crystals resembling dichromate of potassium both in form and colour, when the neutral chromate of barium is treated with an excess of CrO₃; it crystallises on cooling, in clinorhombic prisms. Pure water decomposes it into CrO₃+CrO₃Ba; it is unattacked, however, by glacial acetic acid even when heated; we can thus wash the crystals. *Chromates of Lead.*—When we endeavour to prepare Cr₂O₇Pb we generally obtain a mixture of the neutral salt with a little acid salt (PbCl₂ with CrO₃ in boiling solution, or acetate of lead, CrO₃ and NO₂H). However, we can obtain pure Cr₂O₇Pb in a reddish-brown crystalline powder from acetate of lead, CrO₃ and NO₂H of r₄ density, by boiling them for several hours in a flask fitted with a vertical condenser.—*Berichte*, vol. xxxvi., p. 1740.

Experiments with the Emanation from Bromide of Radium.—In some experiments carried out with the object of showing the dispersion of the emanation of bromide of radium, M. Th. Indricson (*Journ. de la Soc. Phys. Chim. R.*, vol. xxxvi., p. 7) made use of a long tube, the inner surface of which was covered with a layer of Sidot's blende (sulphide of zinc). After having put it into communication with a test-tube containing a solution of bromide of radium (10 m.m. in 10 c.c.), we observe a luminescence appear and travel along the tube. By repeating Ramsay's experiment, the author observed that the yellow line of helium did not correspond exactly with the two yellow lines in the spectrum of the emanation; in fact, it was placed between these two latter. After having plunged the serpentine tube communicating with the test-tube into liquid air, the author observed in the spectrum of the emanation a reinforcement of the lines corresponding to the helium lines, and between the two yellow lines already mentioned appeared a third line corresponding exactly with the yellow line of helium. The helium lines do not exist in the spectrum of the emanation in a recently prepared tube, but only appear after a time. On examining the gases set free during the solution of the bromide of radium, the author observed that the helium lines did not exist as long as the tube remained phosphorescent in the dark. When after four days this phosphorescence had disappeared, the helium lines were observed in the spectrum.—*Revue Generale des Sciences*, 15th Year, No. 13, July 15, 1904.

THE VICTORIA UNIVERSITY OF MANCHESTER. CHEMICAL COURSE.

Full particulars of this Course, qualifying for the UNIVERSITY DEGREES IN CHEMISTRY and the Technological Chemistry Certificate, will be forwarded on application to the REGISTRAR.

The SESSION commences on OCTOBER 4th.

THE DURHAM COLLEGE OF SCIENCE NEWCASTLE-UPON-TYNE.

Complete Courses of Instruction are provided for Students of both sexes proceeding to the University Degrees in Science, or in Letters, and for the University Diploma in Theory and Practice of Teaching. Special facilities are offered for the study of Agriculture, Applied Chemistry, Mining, and all branches of Engineering and Naval Architecture.

Matriculation and Exhibition Examinations begin September 26th. Lectures begin October 4th, 1904.

Prospectuses on application to the SECRETARY.

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

DEPARTMENTS OF CHEMISTRY, TECHNICAL CHEMISTRY, and METALLURGY.

Chemistry	Prof. G. G. HENDERSON, M.A., D.Sc., F.I.C.
Technical Chemistry	Prof. THOMAS GRAY, D.Sc., Ph.D.
Metallurgy	Prof. A. HUMBOLDT SEXTON, F.C.S., F.I.C.

The Courses of Instruction in these Departments are arranged for Students preparing to become Manufacturing or Analytical Chemists, Metallurgists, or Science Teachers. The courses in Chemistry qualify for the Examinations of the Institute of Chemistry and of the Universities of Glasgow, Edinburgh, and London.

SESSION 1904-5 begins on TUESDAY, SEPTEMBER 27th; the ENTRANCE EXAMINATION begins on MONDAY, SEPTEMBER 19th.

CALENDAR (by post 1s. 4d.), containing regulations for the Associateship of the College, may be obtained from the SECRETARY, 38, Bath Street, Glasgow. PROSPECTUS free.

QUEEN'S COLLEGE, GALWAY.

The MATRICULATION EXAMINATION of SESSION 1904-1905 commences on OCTOBER 21st. Matriculation Certificates of any University within the United Kingdom are accepted.

All Lectures, Scholarships, Exhibitions, and Prizes are Open to Students of either sex.

The Scholarship Examinations in Arts, Medicine, and Engineering commence on OCTOBER 20th.

DEPARTMENTS OF SCIENCE, MEDICINE, & ENGINEERING.

Mathematics	Prof. THOMAS JOHN L'ANSON BROWNHILL, M.A., Fellow of St. John's College, Cambridge; Examiner, R.U.I.
Physics	Prof. A. ANDERSON, M.A. (Camb.), Hon. LL.D. (Glasgow), late Fellow of Sidney Sussex College, Cambridge, Member of the Senate of the Royal University of Ireland, President of the College.
Chemistry	Prof. ALFRED SENIER, Ph.D., Berlin.
Natural History, Mineralogy, and Geology	Prof. RICHARD J. ANDERSON, M.A., M.D., M.R.C.S., Eng.; Examiner, R.U.I.
Engineering	Prof. EDWARD TOWNSEND, M.A., D.Sc.; Examiner, R.U.I.
Anatomy and Physiology	Prof. JOSEPH P. FEE, M.D., M.Ch., D.Sc., F.R.U.I.
Practice of Medicine	Prof. JOHN ISAAC LYNHAM, M.D., M.Ch., M.A.O., F.R.U.I.
Surgery	Prof. W. W. BERRINGTON, F.R.C.S.I., M.R.C.P.
Materia Medica	Prof. NICHOLAS W. COLOHAN, M.D., M.Ch.
Gynaecology	Prof. RICHARD J. KINKADE, B.A., M.D., L.R.C.S.I.

Prospectus of the Courses and Regulations for Scholarships, &c., can be had on application to the—

REGISTRAR,
Queen's College, Galway.

TEXT-BOOKS OF PHYSICAL CHEMISTRY. Edited by Sir WILLIAM RAMSAY, K.C.B., F.R.S. NEW VOLUME JUST PUBLISHED.

"Collectively the manuals will form an adequate record of the present state of knowledge in a large and important field of chemistry. We heartily wish well to Sir William Ramsay's venture, and look with interest for the appearance of the succeeding numbers of the series."
—GLASGOW HERALD.

ELECTRO-CHEMISTRY. Part I.—GENERAL THEORY.

By R. A. LEHFELDT, D.Sc.,

Professor of Physics at the East London Technical College.

Including a Chapter on the Relation of Chemical Constitution to Conductivity, by T. S. MOORE, B.A., B.Sc., Lecturer in the University of Birmingham.
Crown 8vo. 5s.

PART II.—Applications to Electrolysis, Primary and Secondary Batteries, &c. [In preparation.]

The Phase Rule and its Applications. By ALEX. FINDLAY, M.A., Ph.D., D.Sc., Lecturer and Demonstrator in Chemistry, University of Birmingham. With 115 Figures in the Text, and an INTRODUCTION TO THE STUDY OF PHYSICAL CHEMISTRY by Sir WILLIAM RAMSAY, K.C.B., F.R.S. Crown 8vo. 5s.

* Sir William Ramsay's "Introduction to Physical Chemistry" is also issued separately, 1s. net.

LONGMANS, GREEN, & CO., 39, Paternoster Row, London, E.C.

CITY OF LONDON COLLEGE,

WHITE STREET and ROPEMAKER STREET,
MOOKFIELDS, E.C.

MICHAELMAS TERM commences OCTOBER 3rd.

CLASSES and LABORATORY WORK in
CHEMISTRY, PHYSICS, BIOLOGY, BOTANY, GEOLOGY, and PHYSIOLOGY. Special preparation for the Examinations of the Pharmaceutical Society, The Conjoint Board. Complete Courses for University Matriculation and Inter, and Final B.Sc., meeting during the Evening and on Saturday.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

THE CHEMICAL NEWS.

VOL. XC., No. 2335.

ADDRESS TO THE CHEMICAL SECTION OF THE BRITISH ASSOCIATION.

CAMBRIDGE, 1904.

By Professor SYDNEY YOUNG, D.Sc., F.R.S.
President of the Section.

THE researches of Hermann Kopp on the molecular volumes and boiling-points of chemical compounds extended over half a century, beginning with his inaugural dissertation on the densities of oxides in 1838, and concluding in 1889 with a review of the whole of the work done on the subject. In his second paper Kopp considered the molecular volumes of solid compounds, and arrived at the conclusion that truly isomorphous substances have the same atomic or molecular volume, but that in other cases the volumes are usually different. Schröder also made the same observation at about the same time.

Now, isomorphous substances have analogous chemical formulae, and are usually of similar chemical character, and it is interesting to notice that at this early date the fact was recognised that close chemical relationship is associated with similarity in physical properties.

For about the first six years Kopp was engaged in the consideration of the results obtained by other observers, and from these results he deduced the most important of his generalisations.

As regards boiling-points, Kopp, in 1842, concluded that a constant difference in chemical composition is accompanied by a constant difference in boiling-point, and he adopted the value 18° as the rise due to the replacement of the methyl by the ethyl group in organic compounds, although the observed differences varied between 11° and 24° . Two years later he found in sixteen comparisons differences varying from 8° to 33° ; but he doubted the correctness of the extreme values, and took 19° as the true value; he further suggested that this is the constant difference for an addition of CH_2 in any homologous series, and he pointed out that the observed difference was most regular in the case of the fatty acids.

Kopp was also of opinion that isomeric compounds with the same composition and the same vapour density have the same boiling-point.

The paucity of experimental data and the wide discrepancies between the results obtained by different observers induced Kopp to undertake the determination of the boiling-points of various compounds, and, later, their molecular volumes at a series of temperatures, and it is interesting to note the comparative crudeness of his first attempts and the increasing attention which he paid to the purification of his compounds and to the elimination of thermometric and other errors. He first examined three pairs of esters in order to find whether isomeric compounds have really the same boiling-points. But he employed only calcium chloride as a dehydrating agent, and this would remove neither water nor the alcohol completely; he was much troubled by the "bumping" of the liquids, and the temperatures he actually observed—with the thermometer bulb in the liquid—fluctuated considerably, and he could only, in most cases, take the lowest temperature observed as the most probable boiling-point. By so doing, and by making a fairly liberal allowance for residual errors, Kopp arrived at the erroneous conclusion that the boiling-points of isomers were the same in the three cases examined, and therefore, probably, in all cases.

The boiling-point of methyl alcohol was of great interest to Kopp, because, taking that of ethyl alcohol—about

which there was general agreement—as correct, it should, according to his law, be $78^\circ - 19^\circ = 59^\circ$, while the temperatures actually observed varied from 60° to 66° . Kopp prepared a specimen of methyl alcohol, and found that it boiled at about 65° ; but he had more faith in his law than in his experimental result, and he concluded that the methods of determining boiling-points were not sufficiently accurate to give results correct to within even 1° or 2° .

In 1854, he discussed the corrections which should be applied to thermometer readings, giving a table of corrections for the unheated column of mercury, and adopting the value 27 m.m. per degree as the value of dp/dt for all substances, in order to reduce the observed boiling-point to that at normal pressure. He pointed out, also, that the height of the barometer should be reduced to 0°C . Taking advantage of Delft's improved method of preparing and purifying methyl alcohol, Kopp made a fresh specimen from methyl oxalate and dried it with lime; but while Delft observed the boiling-point to be 60° , Kopp obtained the value $65.2^\circ - 65.8^\circ$. He was still, however, inclined to think that, owing to bumping, the observed boiling-point was too high, and that the true temperature should be about 60° .

Meanwhile, in 1847, Kopp had examined sixteen liquids, including water, two alcohols, three fatty acids, and seven esters, and in 1854, as a result of his further determinations, he was able to compare the boiling-points—and also the molecular volumes—of a large number of substances, most of which were either alcohols, acids, or esters, and he at first adhered to his previous value of 19° for the rise of boiling-point due to the addition of CH_2 . Later in the same year, however, taking a wider survey and including hydrocarbons and their halogen derivatives, ethers, sulphides, and other compounds, he was obliged to admit that the difference is in some cases higher, in others lower, than 19° , but he still regarded these cases merely as exceptions to the law. In 1867, Kopp admitted that isomeric aromatic hydrocarbons have not always the same boiling-point, and that the difference for an addition of CH_2 was not always 19° ; but he still believed that the difference for CH_2 was constant in any really homologous series—for example, 20.5° for homologues of toluene, 18.5° for those of xylene, and 16.5° for those of trimethylbenzene. He also recognised the fact that isomeric alcohols have widely different boiling-points.

Kopp published no later papers on the boiling-points of organic compounds, although he dealt fully with the question of molecular volumes in his final communication in 1889.

As a pioneer, Kopp had very great difficulties to contend against when he began his researches; data were scanty and far from accurate, and the substances which could be most easily obtained, and, it was thought, readily purified, were, unfortunately, those which were the least likely to lead to normal generalisations. Water, the alcohols, and the organic acids all contain a hydroxyl group, and we now know that the physical properties of these substances are abnormal in nearly all respects, owing probably to the fact that their molecules tend to associate together; moreover, the esters, which are formed by the interaction of acids and alcohols, do not behave quite normally, and there is probably molecular association, though to a much smaller extent than with the hydroxyl compounds.

There can be little doubt that if Kopp had been able, in the first place, to obtain a considerable number of pure substances of normal behaviour, such as the paraffins or their halogen derivatives, he would not have been led to the erroneous conclusions which he defended with such vigour for so many years. If we take the normal paraffins as the simplest class of organic compounds, we find that, instead of the boiling-points rising by equal intervals as the series is ascended, the rise, which is very large for the lowest numbers, becomes smaller and smaller as the molecular weight increases. This fact is, of course, now well known, and various formulæ have been suggested to reproduce these boiling-points. Thus, Walker has proposed the formula $T = aM^b$, where T is the boiling-point on

the absolute scale of temperature, M is the molecular weight, and a and b are constants. Ramage has this year suggested that this formula applies only to the CH_2 chain linkage, and that the influence of the terminal hydrogen atoms is considerable in the case of the lowest members, but diminishes as the chain lengthens, and becomes eventually either constant or negligible. In other words, the lower members of the series cannot be regarded as truly homologous, and that is a point which is, I think, important to bear in mind. Ramage suggests a new formula, $T = n[M(1 - 2^{-n})] + 1$, where n is Walker's constant, 37.3775, and n is the number of carbon atoms in the molecule. He assumes, however, a constant difference for CH_2 in the case of the alcohols, the aldehydes, and the ketones, but I doubt whether the boiling-points of the last two classes of compounds are yet sufficiently well established to allow of any certain conclusions being drawn from them.

I am inclined to think that it may be useful to regard the value of Δ (the rise of boiling-point for an increment of CH_2) as being mainly a function of the absolute temperature, and I would provisionally suggest the formula $\Delta = \frac{144.86}{T^{0.0148}}$, where Δ is the difference between the boiling-point, T , of any paraffin, and that of its next higher homologue. Taking the boiling-point of methane as $106.75^\circ \text{ abs.}$, the values for the higher members agree better with the observed temperatures than those given by Ramage's formula, as will be seen by Table I.

TABLE I.
Boiling-point (abs. temp.)

Paraffin.	Observed.	Calculated. Ramage.	Δ .	Calculated. Young.	Δ .

$\text{C}_{15}\text{H}_{32}$	543.5	544.2	+ 0.7	542.3	- 1.2
$\text{C}_{16}\text{H}_{34}$	560.5	561.9	+ 1.4	558.85	- 1.65
$\text{C}_{17}\text{H}_{36}$	576.0	579.0	+ 3.0	574.7	- 1.3
$\text{C}_{18}\text{H}_{38}$	590.0	595.7	+ 5.7	589.9	- 0.1
$\text{C}_{19}\text{H}_{40}$	603.0	611.9	+ 8.9	604.5	+ 1.5

I do not wish, however, to lay much stress on the actual form of the equation, or on the particular values of the constants; the chief point I wish to call attention to is that Δ may be regarded as a function of the temperature.

Suppose that we replace a terminal atom of hydrogen in each normal paraffin by chlorine, so as to form the homologous series of primary alkyl chlorides. The boiling-points of these chlorides are much higher, and the differences, Δ , are much smaller than for the corresponding paraffins, but the gradual fall in the values of Δ as the series is ascended is unmistakable. The same remarks apply to the bromides and iodides, the boiling-points being still higher and the values of Δ smaller.

But the point of chief interest appears to me to be this: If the values of Δ for the halogen derivatives are plotted against the absolute temperatures, the points for the most part fall near the curve constructed for the paraffins, and represented by the formula $\Delta = \frac{144.86}{T^{0.0148}}$. The first value

of Δ is decidedly low in each case (average deviation from curve 2.7°); the later ones are rather high in nearly every case (average deviation 0.86°). Similar results are in

general obtained with other homologous series of compounds in which molecular association is not believed to occur, but, as will be seen from Table II., the deviations from the normal paraffin curve are greater in the case of those series the lower members of which, according to Ramsay and Shields, are characterised by molecular association.

In the great majority of cases the deviations are greatest for the lowest members of a series, the calculated values of Δ being almost invariably higher than the observed, and this may perhaps be explained in the manner suggested by Ramage. I have therefore divided each series into two groups, the first ending and the second beginning with the lowest member of the series which contains a CH_2 group linked to two carbon atoms. Thus, of the alkyl chlorides, the first group contains CH_3Cl , $\text{CH}_3\text{CH}_2\text{Cl}$, and $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$, and the second group begins with propyl chloride, so that all its members contain one or more $\text{C}-\text{CH}_2-\text{C}$ groups.

In the case of the ethers, esters, and other compounds which contain two alkyl radicals, a series is regarded as homologous when one radical remains unaltered and the other increases by stages of CH_2 . The variable radical only is considered in dividing the series into the two groups; thus, although propionic acid contains a $\text{C}-\text{CH}_2-\text{C}$ group, it remains unchanged in the propionic esters, the first group of which consists of methyl, ethyl, and propyl propionate, the second beginning with the last-named ester. (See Table II.).

TABLE II.

Group.	Lower members.		Higher members.	
	Number of values of Δ .	Mean difference. Calculated—observed.	Number of values of Δ .	Mean difference. Calculated—observed.
Alkyl chlorides	2	+ 2.70°	5	- 1.04°
Alkyl bromides	2	+ 1.12	5	- 1.25
Alkyl iodides	2	+ 0.52	3	- 1.0
Isoparaffins	—	—	2	+ 0.57
Toluene, &c.	1	0.45	3	+ 0.68
<i>o</i> -Xylene, &c.	1	+ 6.1	1	- 0.5
<i>m</i> -Xylene, &c.	1	+ 4.25?	1	+ 4.0?
<i>p</i> -Xylene, &c.	1	0.15	1	+ 0.65
Diethyl benzene, &c. ..	—	—	1	- 0.5
Olefines, $\text{H}_2\text{C}=\text{CHR}$..	—	—	3	- 2.35?
Olefines, $\text{RHC}=\text{CHR}$..	—	—	3	+ 0.5?

Associating Substances.

Cyanides	1	+ 12.65	4	+ 2.9
Nitromethane, &c.	2	+ 11.1	1	+ 3.85
Ketones	1	+ 6.2	3	+ 2.85
Fatty acids	2	+ 5.87	7	+ 1.58
Fatty alcohols	2	+ 12.87	5	+ 5.24

Of the seventeen series of non-associating substances there are only five for which the mean difference between the calculated and observed values of Δ for the higher members exceeds 1.5° .

1. The *m*-xylene series. Here there is only one value, which, I think, is doubtful.

2. The olefines, $\text{H}_2\text{C}=\text{CHR}$. Here two of the three individual differences are less than 1.5° ; the temperatures are all below 0° , and are somewhat uncertain.

3. The polymethylenes. The difference for pentamethylene and hexamethylene differs by less than 1° from the calculated value. The boiling-point of heptamethylene appears very doubtful.

4. The amines. Differences somewhat erratic; three within 1.5° and two within 0.5° . Octylamine and nonylamine clearly incorrect and not values.

5. The esters. Although Ramsay and Shields include these substances as non-associating, there is, I think, reason to suspect slight association.

It will be seen that the differences are greater for associating than for non-associating substances; also that they are greatest for the alcohols and least for the acids, although the factor of association is very high for both these series. In order to arrive at an explanation of these facts the effect of replacing hydrogen by chlorine may first be considered.

The boiling-point of hydrogen chloride is not yet known accurately, but it must be about -80° . Thus, by replacing an atom of hydrogen in the hydrogen molecule by chlorine, the boiling-point is raised from 20.4° abs. to about 193° abs., or about 173° . On replacing an atom of hydrogen in methane by chlorine, the rise of boiling-point is from 108.3° to 249.3° , or 141° . Ascending the series of paraffins the rise of boiling-point due to the replacement of hydrogen by chlorine diminishes rapidly at first, and then more slowly, being only 58.5° in the case of octane. Thus the influence of the chlorine atom becomes relatively smaller as the formula weight of the alkyl group increases.

Consider, now, the effect of replacing a hydrogen atom by a hydroxyl group. In the formation of water from hydrogen gas the boiling-point is raised no less than 352.6° , from 20.4° abs. to 373° abs., or in the ratio of 1:18.3; in the case of methane the rise is 221.8° , from 108.3° to 377.7° , or in the ratio of 1:3.12; with octane the rise is 65.4° , from 398.6° to 464° ; and with hexadecane it is only 56.5° , from 560.5° to 617° , the ratio being 1:1.10.

It will be seen that in the case of hydrogen the influence of the hydroxyl is enormously greater, and in the case of methane very much greater, than that of chlorine in

explanation of the very low values of Δ for the alcohols, and the moderately low values for the acids is thus afforded.

It would take up far too much time and space to give full details of the boiling-points of all the compounds considered, with the observed and calculated values of Δ ; but it may, I think, be stated that the difference between the boiling-point of any non-associating organic compound which contains at least one $\text{C}-\text{CH}_2-\text{C}$ group, and that of its next higher homologue (at any rate up to temperatures of about $300^{\circ}\text{C}.$), may be calculated with an error rarely exceeding 1.5° and generally under 1° , by means of the formula $\Delta = \frac{144.86}{T_{\text{boil}}^{1.48} \sqrt{V}}$. The formula

seems also to be applicable to any ester which contains at least five atoms of carbon in the variable alkyl or acyl group (the mean error for 40 values of Δ is $+0.93^{\circ}$), and with smaller error when the number of carbon atoms is still larger;* it is probably also applicable to the higher fatty acids, cyanides, ketones, and nitro-compounds.

Comparison of Molecular Volumes.

The fundamental idea on which both Kopp and Schröder based their methods of calculating the molecular volumes of organic compounds from the atomic volumes of the component elements was the constancy of the increase in molecular volume for each addition of CH_2 . With regard to this point the question was greatly discussed whether the comparison should be made at the same temperature, say $0^{\circ}\text{C}.$, or at the boiling-points of the compounds under the same pressure. Later, when Van der Waals brought forward his conception of corresponding states, it was thought probable that the comparison should be made at corresponding or equal reduced temperatures; that is to

TABLE III.

Paraffin.	A.		B.		C.		D.		E.	
	Molecular volume.	Δ .	Molecular volume.	Δ .	Molecular volume.	Δ .	Molecular volume.	Δ .	Molecular volume.	Δ .
n-Pentane	111.33	15.44	117.80	22.13	116.13	20.09	116.13	21.06	309.3	56.8
n-Hexane	126.77	15.69	139.93	22.63	136.22	20.18	137.19	21.49	366.1	60.2
n-Heptane	142.46	15.88	162.56	23.70	156.40	20.51	158.68	21.83	426.3	62.6
n-Octane	158.34		186.26		176.94		180.51		488.9	

raising the boiling-point, but that on ascending the series of paraffins to octane the influence of the hydroxyl group diminishes until it is little greater than that of the chlorine atom, and it is quite probable that with hexadecane it would be somewhat less. This is, no doubt, to be explained by the fact that the molecules of water and of the lower alcohols are highly associated in the liquid, but not in the gaseous state, and therefore, in order to vaporise the liquids, this molecular attraction must be overcome, and the temperature must therefore be raised. The molecular association diminishes, however, as the series of alcohols is ascended, and is probably slight in the case of octyl alcohol. If so, it would appear that the effect of the hydroxyl group—apart from association—in raising the boiling-point is not very different from, and is probably somewhat less than, that of the chlorine atom, and that the difference between the boiling-points of the lower alcohols and of the corresponding chlorides is entirely due to molecular association in the liquid state.

With the acids there is association in the gaseous as well as the liquid state, and since, according to the tables given by Ramsay and Shields, the factor of association for a liquid fatty acid at its boiling-point is rarely greater, and in most cases is somewhat smaller, than for the corresponding liquid alcohol, the molecular attraction to be overcome on vaporisation must be considerably less for the acid than for the corresponding alcohol, and the resulting rise of boiling-point above the normal value must be less. An

say, at temperatures which bear the same ratio to the critical temperatures. If the generalisations of Van der Waals were strictly true, the boiling-points under corresponding pressures would be corresponding temperatures, but that is not usually the case. The comparison may therefore be made either at equal reduced temperatures or at the boiling-points under equal reduced pressures; or, lastly, it may be made at the critical points themselves, and, thanks to the law of Cailletet and Mathias, the critical volumes can be ascertained with a great degree of accuracy.

In order to find whether the difference in molecular volume for each addition of CH_2 is really constant, it is best to examine such perfectly normal substances as the paraffins, and the data for four consecutive members of the series—*n*-pentane, *n*-hexane, *n*-heptane, and *n*-octane—are fortunately available.

In Table III. the molecular volumes and the differences, Δ , for an addition of CH_2 are given under the following conditions:—

* Thus the observed boiling-point of *n*-hexyl formate is 173.6° , and the value of Δ calculated from the formula is 22.8 , giving 176.4° as the boiling-point of the next higher homologue. This agrees very well with the observed boiling-point of *n*-heptyl formate, 176.3° , but not with that of *n*-hexyl acetate, 169.2° . Again, the observed boiling-point of methyl caproate (hexoate) is 149.6° , and the calculated value of Δ is 23.0 , giving 172.6° as the boiling-point of the next homologue.

† The observed boiling-point of methyl enanthylate (heptoate) is 172.1° , but that of ethyl caproate is only 166.6° .
‡ The atomic weights ($\text{C}=11.97$, $\text{H}=1$) employed in the original papers are retained.

- A. At 0° C.
- B. At the respective boiling-points under 1 atmosphere pressure.
- C. At equal reduced temperatures (0.6366).
- D. At the respective boiling-points under equal reduced pressures (0.02241).
- E. At the respective critical points.

It will be seen that in every case there is a decided rise in the value of Δ as the series is ascended, but that the rise is relatively smallest when the comparison is made at the particular reduced temperature chosen. At higher reduced temperatures, however, it would be relatively much greater, since it is very marked at the critical point, where the reduced temperature = 1. The rise is also comparatively small at the common temperature 0°, but the comparison would not be satisfactory if a higher common temperature, say 150°, were chosen, because the coefficients of expansion differ considerably; at 150° the values of Δ would be 8.75, 13.45, and 15.38 respectively.

In the case of nine of the lower esters the values of Δ are by no means constant, whether the comparison be made at 0°, at the boiling-point, or at the critical point. The eleven values of Δ vary in the three methods between 16.34 and 18.21, 20.84 and 23.42, 5.43 and 6.17 respectively; but there is not a regular rise with increase of molecular weight.

Both Kopp and Schröder compared the molecular volumes of compounds at their boiling-points under normal pressure, but they deduced quite different values for the atomic volumes of carbon and hydrogen; it is clear, however, that as Δ varies considerably no values whatever for C and H could give accurate results, even in the case of true homologues.

Traube makes the comparison at a common temperature, usually 15°, and takes into consideration both the actual volumes of the molecules and the co-volume, which he assumes to have the same value, $24.5(1+at)$, where $a=1/273$, for all substances. He calculates definite values for the atomic volumes of C and H at a given temperature; thus, at 15°, C=9.9 and H=3.1, or CH₂=16.1, so that here again the difference for CH₂ at a given temperature should be constant.

It does not appear to me that the problem has yet been completely solved, although Traube's method of calculation generally gives much better results than those of Kopp and Schröder.

Comparison of Boiling-points at a Series of Equal Pressures.

The results of this comparison are often exceedingly simple if the two substances compared are very closely related, and if there is no molecular association in either case. Taking, for example, chlorobenzene and bromobenzene, it is found that the ratio of the boiling-points (on the absolute scale of temperature) under equal pressures is constant whatever the pressure may be, or—

$$\frac{T_A}{T_B} = \frac{T'_A}{T'_B} = 1.0590.$$

A similar result is obtained with the other halogen derivatives of benzene with ethyl bromide and ethyl iodide, with ethyl acetate and propyl acetate, and some other pairs of esters; but in some cases of close relationship—for example, with ethyl formate and ethyl acetate—the ratio is not quite constant, and the formula becomes—

$$\frac{T_A}{T_B} = \frac{T'_A}{T'_B} + c(T_B - T'_B),$$

where c has a very low value (0.0000417 for these two esters). When there is no close relationship, but the molecules are not associated, the value of c is usually larger—for example, 0.000185 for carbon disulphide and ethyl bromide.

Lastly, when there is no close relationship and the molecules of one or both substances are associated, the formula—

$$\frac{T_A}{T_A^*} = \frac{T'_A}{T'_B} + c(T_B - T'_B)$$

may no longer hold, and a third term may be required, thus—

$$\frac{T_A}{T_B} = \frac{T'_A}{T'_B} + c(T_B - T'_B) + d(T_B - T'_B)^2;$$

or, in any case, the value of c becomes much higher, as with benzene and ethyl alcohol ($c=0.0008030$) or sulphur and carbon disulphide ($c=0.0006845$).

Behaviour of Liquids when Mixed Together.

There are three points to consider when two liquids are brought together?—(1) Their miscibility, whether infinite, partial, or inappreciable; (2) the relative volumes of the mixture and of the components; (3) the heat evolved or absorbed.

Liquids which are classed as non-miscible rarely, if ever, bear any close chemical relationship. Thus water is practically non-miscible with all hydrocarbons, and with their halogen and many other derivatives; again, mercury, so far as I know, is not miscible with any liquid compound, organic or inorganic. It is true that the higher aliphatic alcohols are almost insoluble in water, although there may be said to be some chemical relationship between them, inasmuch as an alcohol may be regarded as an alkyl derivative of water. But the alcohols may also be looked upon as hydroxyl derivatives of the hydrocarbons, and, the higher the formula weight of the alkyl group, the greater is its influence, relatively to that of the hydroxyl, on the properties of the alcohol. Thus, while the lower alcohols show considerable resemblance to water—for example, in their behaviour with dehydrating agents, such as sodium, phosphoric anhydride, or lime, and in their power of uniting with metallic salts to form crystalline alcoholates corresponding to the hydrates—this resemblance diminishes as we ascend the series, and is generally not observable with the higher members.

On the other hand, the higher the molecular weight of the alcohol the closer is its resemblance to the hydrocarbon from which it is derived. This, as already mentioned, is well shown by the diminishing difference between the boiling-points of the alcohol and paraffin as the series is ascended; it may also be noted that methane was long classed as a permanent gas, while methyl alcohol is a liquid; whereas both hexadecane (C₁₆H₃₄) and cetyl alcohol (C₁₆H₃₃OH) are solids, the former melting at 18° and the latter at 50°.

It may, in fact, I think, be stated that the chemical relationship between water and methyl alcohol is fairly close, while that between water and cetyl alcohol is very distant. So, also, two adjacent members of a homologous series, such as methyl and ethyl alcohol, are more closely related than two members of widely different molecular weight, such as methyl and cetyl alcohol.

Adopting this view, it is, I believe, safe to state that liquids which are chemically closely related to each other are invariably miscible in all proportions.

As regards the relative volumes of a mixture and of its components at the same temperature, it is well known that inequality is the rule and equality the exception; and, further, that contraction is more frequently observed than expansion on admixture. So far, however, as experimental evidence is available, it appears that when the liquids are very closely related to each other the change of volume is exceeding small. For example, with ethyl acetate and propionate in equimolecular proportions, +0.015 per cent; toluene and ethyl benzene, -0.034 per cent; *n*-hexane and *n*-octane, -0.053 per cent; methyl and ethyl alcohol, +0.004 per cent; chlorobenzene and bromobenzene, no change.

When the relationship is less close the changes are usually, but not invariably, larger, and are in some cases positive, in others negative; and it is rarely possible, in the present state of our knowledge, to predict from the nature of the substances—unless one is basic and the other acidic in character—whether contraction or expansion is to be expected. Thus, when methyl alcohol is mixed with

water considerable contraction occurs, although the relationship is less close than between methyl and ethyl alcohol, which expand to a minute extent on mixing.

All we can say with regard to the alcohols is that, the higher the molecular weight—or, if isomeric alcohols are included, the higher the boiling-point—the smaller, as a rule, is the contraction on mixing with water.

Very similar remarks apply to the heat changes which occur on mixing liquids. It appears that in the case of very closely related substances these changes are exceedingly small, or negligible, as is indicated by the very minute change of temperature which has been observed, thus:—Ethyl acetate and propionate, -0.02 ; toluene and ethyl benzene, $+0.05$; *n*-hexane and *n*-octane, $+0.06$; methyl and ethyl alcohol, -0.10 ; chlorobenzene and bromobenzene, 0.00 .

It might be expected that in the case of less closely related substances contraction would be accompanied by evolution of heat and expansion by absorption of heat, but this is by no means invariably the case; for example, on mixing 40 gm.-molecules of propyl alcohol with 60 gm.-molecules of water there is a contraction of 1.42 per cent, but a fall of 1.15° in temperature was observed. Taking the alcohols as a group, it is found that, the higher the boiling-point, the smaller is the heat evolution, or the greater the absorption on admixture with water.

Properties of Mixtures.

The behaviour of two non-miscible liquids when heated together is well known, and I need only refer to the fact that the vapour pressure is equal to the sum of the vapour pressures of the pure components at the same temperature; that the boiling-point is the temperature at which the sum of the vapour pressures of the components is equal to the pressure under which the liquid is being distilled, provided that evaporation is taking place freely, and the vapour is not mixed with air; and, lastly, that the composition of the vapour is independent of that of the liquid (so long as both components are present in sufficient quantity), and is expressed by the equation—

$$\frac{x_A}{x_B} = \frac{P_A D_A}{P_B D_B}$$

where x_A and x_B are the relative weights of the two components in the vapour, P_A and P_B their vapour pressures at the observed boiling-point, and D_A and D_B their vapour densities.

The vapour pressure, boiling-point, and vapour composition, then, can be calculated for non-miscible liquids, and it has been stated that such liquids have never any close chemical relationship, and are usually not related at all.

On the other hand, it has been mentioned that when the chemical relationship is very close the liquids are invariably miscible in all proportions, and that there is very little, if any, volume or heat change on admixture.

So, also, the vapour pressure and boiling-point of a mixture of closely related liquids are easily ascertained from those of the pure components, and the composition of the vapour bears a simple relation to that of the liquid.

The vapour pressure of the mixture is given, at any rate with a very close approach to accuracy, by the equation $P = mP_A + (100 - m)P_B$, where P , P_A , and P_B are the

vapour pressures of the mixture and of the components, A and B , at the observed boiling-point, and m is the molecular percentage of A .

Van der Waals concluded from theoretical considerations that this relation should be true when the critical pressures are equal and the molecular attractions agree with the formula proposed by Galtzine and by D. Berthelot, $a_{12} = \sqrt{a_1 a_2}$, where a_{12} represents the attraction of the unlike molecules, and a_1 and a_2 the respective attractions of the like molecules. That is certainly the case with

chlorobenzene and bromobenzene, which, as already mentioned, show no heat or volume change on admixture, for the maximum difference between the observed and calculated pressure in three experiments was less than 0.1 per cent.

But the relation is, at any rate, very nearly true for closely related substances when the critical pressures are not equal, for in the case of methyl and ethyl alcohol the difference between the observed and calculated pressure was within the limits of experimental error, and with four other pairs of closely related substances the greatest mean difference (for three readings each) was only 0.6 per cent. It is not, however, as Speyers suggested, true for all non-associated substances, whether closely related or not; indeed, chemical relationship seems to be much more important than the state of molecular aggregation, for the relation is true for methyl and ethyl alcohol, while it is altogether untrue for benzene and hexane.

The boiling-point of a mixture of closely related liquids may be ascertained from the vapour pressures of the components, but not so simply as in the case of non-miscible liquids, because the boiling-point depends on the composition of the liquid.

In order to calculate the boiling-points of all mixtures of two closely related liquids under normal pressure, we should require to know the vapour pressure of each substance at temperatures between their respective boiling-points under that pressure. Thus, chloroform boils at 132.0° and bromobenzene at 156.1° , and we must be able to ascertain the vapour pressure of each substance between 132° and 156° .

The percentage molecular composition of mixtures which exert a vapour pressure of 760 m.m. must then be calculated at a series of temperatures—say, every two degrees—between these limits by means of the formula—

$$m = 100 \cdot \frac{P_B - P}{P_B - P_A}$$

where, in this case, $P = 760$.

Lastly, the molecular percentages of A , so calculated, must be mapped against the temperatures, and the curve drawn through the points will give us the required relation between boiling-point and molecular composition under normal pressure. In the case of six pairs of closely related liquids the greatest difference between the observed temperature and that read from the curve constructed as described was 0.27° .

For liquids which are not closely related, the differences are usually much greater, and particular mixtures of constant (minimum or maximum) boiling-point are not unfrequently met with, especially when the molecules of one or both substances are associated in the liquid state.

The formula for the composition of the vapour from a mixed liquid suggested independently by Berthelot and by Wanklyn,—

$$\frac{x_A}{x_B} = \frac{W_A P_A D_A}{W_B P_B D_B}$$

(where x_A and x_B , P_A and P_B , D_A and D_B have the same meaning as in the equation for non-miscible liquids, and W_A and W_B are the relative weights of the two components in the liquid mixture), was shown by F. D. Brown to be incorrect, and he proposed the simpler formula—

$$\frac{x_A}{x_B} = c \frac{W_A}{W_B}$$

where c is a constant which does not differ greatly from $\frac{P_A}{P_B}$. The subject was investigated mathematically by

Duhem and by Margules, and experimentally and mathematically by Lefheldt and by Zawidski. The two last-named observers deduced workable formulae from the fundamental equation of Duhem and Margules, and it is noticeable that both Lefheldt's and Zawidski's formulae, in their simplest

form, become identical with Brown's. Zawidski's, however, assumes the form—

$$\frac{x_A}{x_B} = \frac{P_A}{P_B} \cdot \frac{W_A}{W_B}.$$

This formula is certainly not, as a rule, true for mixtures of liquids which are not closely related; but, on the other hand, in the very few cases examined the equation

$\frac{x_A}{x_B} = c \cdot \frac{W_A}{W_B}$ appears to hold for those mixtures for which the equation—

$$P = \frac{m P_A + (100 - m) P_B}{100}$$

is true; that is to say, generally, for closely related liquids.

The question, however, whether $c = \frac{P_A}{P_B}$ is an open

one; but it is interesting to remark that if this equality holds it should be possible in many cases to calculate the vapour pressure at any temperature, the boiling-point under any pressure, and the composition of the vapour of any mixture of two closely related liquids, if the boiling-point of one of them under any one pressure, and the vapour pressures of the other within sufficiently wide limits of temperature, are known. For the boiling-points on the absolute scale of the two liquids at the same pressure bear a

constant ratio to each other, or $\frac{T_A}{T_B} = \frac{T'_A}{T'_B}$; hence the

vapour pressures or boiling-points of one substance can be calculated if those of the other are known. Again, from the vapour pressures of the pure substances we can calculate the vapour pressures and the boiling-points of all

mixtures; and, lastly, if $c = \frac{P_A}{P_B}$, we can make use of Brown's formula,—

$$\frac{x_A}{x_B} = c \cdot \frac{W_A}{W_B},$$

to calculate the composition of the vapour from all mixtures without carrying out special experiments to find the value of c . It is, therefore, a matter of considerable

interest to ascertain whether c is really equal to $\frac{P_A}{P_B}$ or not.

When the equation $P = \frac{m P_A + (100 - m) P_B}{100}$ does not

hold good, a modification of Brown's formula, or that of Leheldt, or of Zawidski, must be employed to calculate the vapour composition, and the constants for those formulæ must first be determined experimentally.

Other physical properties, such as the refractive power of mixtures, might be considered, but I will only refer to the critical temperature and pressure. In 1882, Pawlewski stated that the critical temperature of a mixture could be calculated from those of the components by the formula

$$\theta = \frac{m \theta_A + (100 - m) \theta_B}{100}, \text{ where } m \text{ is the percentage by}$$

weight of A; and G. C. Schmidt, in 1891, carried out experiments to test the correctness of the statement, purposely choosing substances of widely different physical properties. The differences between the calculated and observed temperatures were not, as a rule, very great, rarely exceeding 4°, and Schmidt considered that they might, to some extent, be accounted for by partial decomposition of one or other component.

Such determinations are, however, liable to serious errors. It is exceedingly difficult to fill a tube with the required amount of a liquid mixture of known composition quite free from air, and although the composition of the very small amount of liquid employed might be determined after the experiment from its specific refractive power, it

would be necessary to know the specific refractive powers of the two components and of mixtures of them. Schmidt does not state how he prepared his mixtures and determined their composition.

Again, when a liquid mixture is heated in a sealed tube, fractionation goes on, so that the more volatile component tends to accumulate in the upper part of the tube, leaving the less volatile component in excess below, and unless a stirring arrangement, such as that devised by Kuenen, is employed, many hours would elapse before complete admixture by diffusion took place at the critical point.

By far the most important and accurate experiments on this subject have been carried out by past or present pupils of Professor Kamerlingh Onnes, notably by Professor Kuenen; and it is quite certain that the formula of Pawlewski cannot be generally true for mixed liquids, for, just as we may have mixtures of minimum or maximum boiling-point, so also, as Kuenen has shown, mixtures of minimum or maximum critical temperature may exist. Thus the critical temperature of carbon dioxide is 31.1°, and of ethane 32.0°, but that of a mixture containing 30 molecules per cent of carbon dioxide is 18.8°. The question remains, however, whether some such law as that proposed by Pawlewski may not hold good for closely related substances. In certain cases, when the relationship is very close (for example, C₆H₅Cl and C₆H₅Br), the critical pressures are equal, or very nearly so, and it seems probable that the critical pressure would be the same for any mixture as for the components. Such a case as this would be likely to give the simplest possible relation between the critical temperatures of a mixture and those of its components; and although the critical temperatures of these substances are inconveniently high, there are, no doubt, others which might be employed—perhaps ethyl chloride and bromide, or possibly carbon dioxide and carbon disulphide. I imagine, however, that Pawlewski's formula would be more likely to hold if m represented the molecular percentage, and not the percentage by weight of A.

In the case of homologous compounds, paraffins, ethers, esters, and so on, the critical pressures are not equal, and it would be necessary to find whether the critical pressures of mixtures are represented by the formula

$$P = \frac{m P_A + (100 - m) P_B}{100} \text{ (where } m \text{ is the molecular per-}$$

centage of A), and also whether any such simple formula is applicable to the critical temperatures.

Kuenen has made some observations with mixtures of ethane and butane containing 2.5 and 5 molecules per cent of butane, and at the conclusion of his paper he says:—"If there was a simple law connecting the critical constants of mixtures with those of the constituents, we might calculate the constants for the second substance (those of the first being known). But such is not the case. Pawlewski's law that the critical temperature is proportional to the composition, expressed in weight units, is very inaccurate, the deviations being sometimes considerable in both directions."

It would, I think, be of great interest if Professor Kuenen could find time to carry out further experiments with mixtures of ethane and butane in order to settle this point, or, perhaps, with *n*-hexane and *n*-octane, both of which can be more easily obtained in a pure state.

From what has been said it may be concluded that, in order to ascertain the normal behaviour of pure substances under different conditions, or to find the simplest relations between the boiling-points, molecular volumes, or other physical constants of a series of substances, or, again, to ascertain the normal behaviour of substances when mixed together, and the properties of the mixtures as compared with those of the components, it is undoubtedly advisable—at first, at any rate—to confine our attention to substances of which the molecules show no signs of association in either the gaseous or liquid state.

In the case of mixtures it is also best to begin with substances which are chemically closely related to each other.

ON THE PROBABLE PRESENCE IN THE SUN
OF THE NEWLY DISCOVERED GASES OF THE
EARTH'S ATMOSPHERE.

By G. D. LIVEING, M.A.,
Professor of Chemistry, University of Cambridge.

Soon after the publication of the list of wave-lengths of the rays which Professor Dewar and I found to be emitted by the most volatile gases of the atmosphere, Stassano pointed out that the bright rays of solar protuberances, of which the wave-lengths had been measured by Deslandres and Hale, agreed closely with rays in our list. The wave-lengths need to be determined with very great exactness in order to prove coincidence, and neither set of wave-lengths have, as yet, been measured with such nicety as that. Nevertheless the agreement is sufficient to make it probable that the same gases are concerned in the production of the rays in question.

When, in the *Astrophysical Journal* for June last, Humphreys published a list of wave-lengths of 339 bright rays of the chromosphere and corona, which he had photographed in Sumatra during the total eclipse of May, 1901, I compared this list with our list of the wave-lengths of rays of the most volatile atmospheric gases, and with those of xenon and krypton, which we had subsequently published, and with those of argon. The result was that of the 339 rays in Humphreys' list 209 do not differ in wave-length by more than one unit from rays emitted by gases of the earth's atmosphere. In our published lists the wave-lengths are given to four figures only in Rowland units; those of Humphreys' list are given to tenths of a unit, so that we are far from being able to prove coincidence in any case. Nevertheless it is so very probable that every gas which is in the earth's atmosphere is also in the sun's, and so much more likely that rays appearing in the chromosphere at a height of nine seconds of arc, or 4000 miles, above the photosphere, should be due to gases of great volatility than to such metals as titanium or strontium, that it is much safer to treat the question as an open one than to assume that titanium and other metals of high atomic weight are always present in the state of vapour at such a distance from the sun's surface, while much more volatile metals, such as sodium, are not regularly present at a quarter of that height.

We have been expecting from Mr. Baly for a long time past a list of wave-lengths of the gases neon, krypton, and xenon determined with great exactness by the use of a grating. The announcement that these measurements were in progress was made more than two years ago, and when the list appears we shall be in a better position to judge of the nearness of the coincidences. Meantime I have re-measured some of the rays of the most volatile gases, still, however, with only a prismatic spectroscope, so as to get, approximately, the fifth figure of the wave-length, and the result has been in many cases to bring my figures into closer agreement with those of Humphreys. The exactness of Humphreys' wave-lengths is quite as important a factor in the settlement of the question as that of mine. He obtained six photographs on celluloid films with a large concave grating of 30 feet focal length, used without any slit. The first had an exposure of two seconds immediately after second contact. Two seconds sufficed for a change of film, and then the second film was exposed for five seconds, and the third for fifteen seconds; the fourth had a lengthened exposure of two minutes during the middle of totality, the fifth fifteen seconds, and the sixth eight seconds, ending three seconds before third contact. The dispersion of the spectrum was so great that 1 m.m. on the film corresponded to 3.66 Angstrom units, and the range of the spectrum depicted extended from λ 3118 to λ 5204. The latter limit was probably determined by the want of sensitiveness of the films to lower green rays, for it would have been of great interest if the range had included the most characteristic rays of coronium, krypton, and neon. At the upper end the Fraunhofer

line S is just excluded. This, too, is to be regretted, as S is a triple line of iron very unlikely to be reproduced by any mixture of elements excluding iron. The dispersion is ample for very exact determinations of wave-length if there were no difficulties in the way of exact measurement. Humphreys has met these difficulties as best he could, and I do not propose to discuss them now, but I may perhaps explain one or two of them. The station where the photographs were taken was near the northern limit of totality, so that the duration of totality was less than half what it was in the centre of the shadow. From these durations of totality I have calculated that the points of contact of the limbs of sun and moon were each nearly 63° from the diameter of the sun parallel to the line of the moon's apparent motion; and the instrument was so arranged that the ruling of the grating was parallel to that line, and in consequence the dispersion at right angles to that line, and the definition affected as little as possible by the moon's motion relative to the sun. During the exposures the tangents at the centres of the small arcs photographed would at first be inclined at about 27° to the direction of the moon's path, and would gradually swing round until at mid totality they would be parallel to it, and then on until they were again inclined at about 27° to that direction, but on the opposite side. This motion tends to blur the definition of the arcs, but the effect would be very small on the first, second, and sixth films, and not great on the third and fifth, but it would be very great on the fourth film for rays emitted only from parts of the chromosphere at much less distance than seven seconds of arc from the sun's limb. Rays emitted from the chromosphere at heights exceeding $7.3''$ would give arcs crossing the direction of dispersion at right angles, and would have well-defined edges on the inside, unaffected by the moon's motion. There are, however, very few of such rays besides H and K and the strong hydrogen and helium rays.

The wave-lengths had to be determined by measuring the distances between the arcs on the films in the direction of dispersion, and interpolating between such of the arcs as could be identified as due to rays of which the wave-lengths were well known. Rays answering to this test would be those above mentioned, namely, H and K and the strong rays of hydrogen and helium, and one or two very characteristic groups, such as the *b* group of magnesium, and, perhaps, the iron triplet 4046-4071. Indeed, on looking through the list I do not see any ray other than these which I could identify with certainty without assuming it to be a reversal of a Fraunhofer line. Humphreys does not say which rays he used as fiducial rays between which he could interpolate. Those which I have just named seem to me too few, and too unequally distributed through the spectrum, to give very trustworthy wave-lengths in all parts of the spectrum. No scale of reference, made with artificial light and the same grating used without a slit, could well be made, or had, in fact, been attempted.

In his list Humphreys gives, against each chromospheric ray, the Fraunhofer line in Rowland's list which has the wave-length nearest to that found for the chromospheric ray. As there are 13,595 lines in Rowland's list in the range of the spectrum embraced by Humphreys' 339 lines, it is not surprising that a Fraunhofer line is to be found for every one of Humphreys' lines, so close that the difference of wave-length is in most cases less than a tenth of a unit and rarely exceeds two-tenths. In discussing his results he evidently assumes the rays to be identical, and ascribes them to the metal (if any) indicated by Rowland. There are, however, some remarkable exceptions to this. They are the rays of helium, and the ultra violet rays of hydrogen which do not appear as Fraunhofer lines. He does not hesitate to ascribe four rays to helium and twenty-four others to hydrogen in preference to identifying them with the nearest Fraunhofer lines. And I think he is right in so doing, notwithstanding the fact that several of these rays have never been observed to be emitted by hydrogen, have not been seen in the spectrum of any star, and are believed to be due to hydrogen only because the wave-lengths found

for them agree closely with the values found by calculation for the prolongation of the well-known series of hydrogen rays.

It is a noteworthy fact, that whereas it is very difficult to get from a tube containing a residue of carefully purified hydrogen any rays of this series above $H\epsilon$, λ 3889, yet when the tubes contain sensible quantities of helium and neon they readily give many lines of the series. Up to $H\epsilon$, λ 3691.5, these rays give very long arcs on Humphreys' films, and are therefore emitted from the upper layer of the chromosphere. Why the presence of helium and neon along with hydrogen should conduce to the development of this series I cannot guess, but whatever the cause it seems to prevail in the sun. Besides the four helium rays above mentioned, other three helium rays might well be identified with arcs on Humphreys' films; λ 3613.78 is much nearer in wave-length to Humphreys' ray λ 3613.8 than the scandium ray with which he identifies it; and λ 4143.92 is nearer to λ 4144.0 than the iron ray to which it is ascribed; and Humphreys' ray 3820.7 gives a very long arc on film IV., and is probably the rather strong helium ray λ 3819.75. There are two rays, λ 3388 and λ 3456.5, giving arcs very long, broad, and hazy, which Humphreys cannot distinguish by measurement from Fraunhofer lines ascribed to titanium, but doubts whether they are really due to that metal. We have found that the most volatile atmospheric gases, probably neon, give rays at about λ 3388.8 and λ 3456.8; the former is rather a strong ray, the latter a weak one. It is possible the solar rays may be identical with them.

That the same gases must be in the atmospheres of the sun and planets appears to me certain. The subject has been discussed by many, but some of them seem to have gone off the track in ascribing the diffusion of these atmospheres to those molecules which, on the kinetic theory, chance to acquire such a velocity as will carry them beyond the attraction of the planet with which they had been associated. Dr. Bryan has calculated that if we suppose the earth's atmosphere to have a definite surface, there is practically no probability that any appreciable amount, of even so volatile a gas as hydrogen can escape with such velocity from that surface that it will not return, provided it be actuated only by the kinetic energy of the gas and by gravitation. Dr. Bryan is careful to point out that other considerations may entirely alter the problem. Now, the postulate of a definite surface to the earth's atmosphere and no gas to be encountered outside it cannot be conceded, nor can the motion of the earth in its orbit be left out of account. If we talk of a gas leaving the atmosphere we need define the limit of the atmosphere, and that is not easy. I do not think that it has any definite limit, but we may make an arbitrary one. Shall we say that when the density is reduced to $1/10^{12}$ of what it is at the earth's surface we have reached that limit? At all events, I do not think there is any evidence that the density of the residuum of gas in planetary space is less than that. If we take Dr. Bryan's figure (derived, I think, from Lord Kelvin), that the number of molecules in 1 c.c. of gas at normal pressure and temperature is approximately 10^{21} , and suppose it reduced to $1/10^{12}$ of that, we shall still have 10^9 molecules left in each cubic centimetre, and a molecule running into such a crowd has as good a chance of being knocked further away as it has of getting back. In fact, if we consider a layer of air at this density, 1 c.c. thick, all round the earth, and remember that the free path is very long, even if we suppose that the molecules all have only the average kinetic energy due to their temperature, many of them will, in a small fraction of a second, have passed far into the layers outside, and it is an equal chance whether the same molecules get back, or others are knocked back instead of them. We do not know at all what the temperature of the residuum of gas in planetary space may be, but it is probably very different from that which a black body would assume if left there. The diffusion of each layer into those above and below it will go on, even at a low temperature, with rapidity; and though

it is true that the layer will contain but an infinitesimal fraction of the earth's atmosphere, yet as it is diffused into neighbouring layers in a small fraction of a second, and there are more than thirty millions of seconds in a year, and the solar system has been many millions of years in settling into its present state, there has been time enough for some considerable interchange of the atmospheres of the sun and earth. It is, however, far more probable that the solar system has settled into its present state from a nearly uniform gaseous mass, than that the materials out of which the sun and planets have been aggregated should have been distributed in such a heterogeneous way as to give a marked distinction between the atmospheres. Nor can we suppose that the sun and planets can have licked up all the gases out of planetary space. For if we could suppose that, and the earth with its atmosphere moving through empty space, the incoherent atmosphere must, I suppose, distribute itself in a long trail throughout the earth's orbit, and this trail would rapidly diffuse into the void space, and the process of diffusion would go on until the amount lost by the earth in its course was counterbalanced by the amount licked up, in fact until gas at a certain average density was distributed throughout the whole of the space in which the earth circulates. That average density will be the same whether we suppose the earth to start with its atmosphere in void space, or to start with a less dense atmosphere in space filled with gas of greater density than that average. Also the distribution of the several gases which have molecules of different masses will ultimately be the same in these two cases. The proportion of gases of smaller molecular mass will increase outwards from the earth's surface as well as from that of the sun, and the interchange between the sun and earth will go on most quickly in the case of the gases of least molecular mass, or, in fact, those which are most volatile. —*Proceedings of the Cambridge Philosophical Society*, vol. xii., Part 2.

ON THE ACTION OF WOOD ON A PHOTOGRAPHIC PLATE IN THE DARK.*

By WILLIAM J. RUSSELL, Ph.D., F.R.S.

It has been shown in former papers that many substances are capable of acting on a photographic plate in the dark,

FIG. 1.

and producing a picture of themselves. Further investigation shows that this property belongs probably to all

* Abstract of a Paper read before the Royal Society, June 16, 1904.

woods, some, however, being much more active than others.

To obtain a picture the wood has to be in contact or at a little distance above the photographic plate, and has to remain there for times varying from half-an-hour to eighteen hours, and to be at a temperature not higher than 55° C.

seen in the wood are very sharp and strongly pronounced in the picture. If the action exerted on the plate be owing to the presence of hydrogen peroxide, as has been previously suggested, no doubt it is produced by the resinous bodies present in the wood, but it is remarkable that there is no action from the dark autumn wood. Experiments

FIG. 2.

FIG. 3.

The wood of the conifers is very active, and gives pictures which are very definite. Fig. 1 is a picture of a section of a branch of a Scotch fir, and shows well the rings of spring and autumn growth. It is remarkable that the former are very active, producing in this picture the dark rings, and so with the other pictures, the part which is active in the original is dark in the picture. The rings

described in the full paper shows that resin exists in the dark rings, but apparently under such conditions that it cannot escape. Other members of the pine group have been experimented with, and have been found to behave in the same way as the Scotch fir.

With the spruces the action on the plate is not so definite and well marked; the white wood is always active, but in

some cases the dark rings are also active, and the pictures are not so sharp as with the firs. Larch wood gives a very interesting result, for the picture is the reverse of that of the Scotch fir, that is, the dark rings in the wood are the active rings and the light rings are inactive.

With regard to woods other than conifers, oak and beech are both active, and give very good pictures, so also does acacia (*Robinia*), Spanish chesnut, and sycamore; on the other hand, ash, elm, horse chesnut, plane, are comparatively but slightly active. In the full paper lists of woods are arranged according to their activity.

Many foreign woods are very active, but as the annual rings are often not well developed, the pictures they give are of a somewhat different character. The African black wood, rose wood, cocobola, and many others are very active. Several of the foreign woods have a ring of white wood which is quite inactive.

Knots in a wood generally, but not always, give a good picture. Some of the resin in immediate contact with the knot is in some cases but little active. The marked difference in properties of resins from different sources is described, and it is shown how difficult it is to remove it, so that the wood shall be no longer active. Boards that have been exposed to the air for a long time, an oak box a hundred or more years old, rotten wood from the stump of a tree, and even bog wood, have all been found to be still active.

In addition to woods many different resins and allied bodies can, when used alone, be proved to be very active, some naturally much more so than others. Ordinary resins, Burgundy pitch, gum mastic, are very active, asphaltum, dragons blood much less so, but true gums, such as gum senegal and gum arabic, are entirely without action on a photographic plate.

In certain cases the picture obtained on the plate does not resemble the markings which are visible on the wood. With some woods this more commonly occurs than with others. That this picture is persistent in the wood is shown by fresh sections giving the same result. The true bark of a wood is apparently quite without action on a photographic plate, so is the internal pith of a plant.

There is another and a very interesting action, which occurs with wood—it is the great increase of activity which it exerts on a photographic plate after it has been exposed to a strong light. For instance, if a piece of deal be half covered by black paper or tin-foil and be exposed for five to ten minutes to bright sunlight, and then put up in the usual way with a photographic plate, it will give a dark picture where the light has fallen on the wood and only a very faint picture of the part which has been covered. This is shown in Fig. 2. Even comparatively inactive woods, such as elm and ivy, after a short exposure to bright light give good and dark pictures. The action is not an indiscriminate darkening over the whole wood section, but an intensifying of the parts already active. This increase of activity by the action of light appears to occur with all woods. Artificial light, such as that from the electric arc, or from burning magnesium ribbon, act in the same way, so does even a faint light. A piece of wood put at a window for some hours will give a darker picture than a similar piece left in the middle of the room. This increase of power of a wood to produce a picture does not rapidly pass away. After twenty-four hours the action is visibly less, and decreases more rapidly at first than after some days, but it will be a fortnight or may be a month before the wood resumes its former condition. This action, like the former one, is entirely stopped by interposing the thinnest piece of glass or mica between the photographic plate and the active body. An inactive card painted with an alcoholic solution of resin acts in the same way, and turpentine which has been exposed to a bright light acts more strongly on a photographic plate than it does when it has not been so exposed. Again, old printing which is now nearly inactive becomes much more active after exposure to sunlight. Bodies other than those which may contain resin or allied

substances are not affected in this way by light; for instance, flour, sugar, porcelain; metals are not rendered active by sunlight.

The next point was to ascertain which of the constituents of light was most active in producing these effects, and the first experiments were made by simply placing strips of different coloured glass on wood sections, exposing them to sunlight, and afterwards putting them up with the photographic plate in the usual way. Pictures of the results are given in the paper. Red glass entirely prevented any increase in the activity of the wood; in fact, it acted in the same way as a band of black paper or tin-foil would act, and a green glass acted much in the same way, but under a blue glass the activity of the wood was increased to much the same extent as under colourless glass or under no glass. Fig. 3 shows what happens when a red glass and a white glass are placed upon it and is exposed to sunlight. On the right of the figure there was no glass.

Further experiments were made by placing similar pieces of deal in light which had passed through different coloured solutions. Three double-case bell-jars were taken, one was charged with a solution of potassium bichromate, another with copper ammonium sulphate solution, and the third with pure water, and all were exposed to sunlight for four hours. The deal in the red light gave only a faint picture, that in the blue light a dark picture, and that with the pure water was only a slightly darker picture. Resin, guaiacum, copal varnish, white oil paint, and resin sized paper all acted in the same way, and gave similar results.

The light from an arc lamp when passed through a red glass and allowed to fall on a wood section for one and a-half hours produced no effect, but when the same light was passed through a blue glass and fell on a similar wood section for only one hour it produced a dark picture. With liquids this same increase of activity by the action of blue light is produced. Turpentine, which has been exposed to blue light, is more active than when in its ordinary condition.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING JULY 30TH, 1904.

By SIR WILLIAM CROOKES, F.R.S.,
and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, August 10th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board, the results of our analyses of the 211 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from July 1st to July 30th inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 211 samples examined by us during the month, all were clear, bright, and well filtered.

July has been on the whole a dry month, though there has been an excess of rain. The rainfall recorded at

Oxford was 3.35 inches, of which 2.43 inches fell on the 25th, 26th, and 27th. The average fall for July is 2.49 inches; thus we have an excess of 0.86 inch, which, added to the previous excess of 1.37 inches, makes a total excess of 2.23 inches, or 16.7 per cent above the thirty-five years' average.

Our bacteriological examinations of 381 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 377 others from special wells, standpipes, &c., making 758 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 26 samples) ..	157.2
New River, filtered (mean of 73 samples) ..	8
Thames, unfiltered (mean of 26 samples) ..	7589
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 205 samples) ..	17
Ditto ditto highest	296
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	567
River Lea, from the East London District clear- water wells (mean of 25 samples) ..	11

Of the 303 daily samples taken from the general filter wells of the Metropolitan Water Board, eighteen samples, or 6.0 per cent, were sterile. Seven samples, or 2.3 per cent, contained more than 100 microbes, and of these four samples contained more than 150 microbes per c.c. The seven excess samples contained an average of 177 microbes per c.c. In June nine excess samples contained an average of 152 microbes per c.c.

Our analytical and bacteriological results show that the high degree of purity recorded during the past three months has been surpassed during July. The organic matter in solution in the London waters is lower now than it has been since August, 1901.

We are, Sir,
Your obedient Servants,
WILLIAM CROOKES.
JAMES DEWAR.

A NATURAL CHEMICAL RULE.

By ARTHUR JAKUES.

THE salts of a considerable number of metals form compounds with ammonia. In some cases it appears that the metal is absorbed into the ammonium radicle, while in others it is more probable that the combination is purely intermolecular—so to express it,—that the salt combines directly in some way with ammonia, without any direct atomic action between the metal and the nitrogen.

A very large number of the metals form compounds in which they function as acid-forming elements, another metal appearing as the base.

A careful examination shows that, in general, no metals form compounds belonging to both these classes. (Of course, in the case of the rarer elements information is not easily obtained).

Whether this is merely coincidence or is due to some common cause it is impossible to say. The marked adherence to the above rule, however, is very noticeable.

The accompanying table shows the behaviour of all the metals with regard to which information has been obtained on the points in question.

In the column marked A are placed those metals which are absorbed into the ammonium radicle; in that marked B, those whose salts combine intermolecularly with ammonia.

Only those metals which appear as acid-forming elements in oxy-salts are placed in the first column; for substances such as "potassium chloroplatinate" are merely double chlorides, and although in certain cases there are grounds

for considering one metal as acidic to the other, it is impossible to say where the true acidity begins.

Again, only those metals whose salts combine with ammonia are placed in the two divisions of the second column; amides, nitrides, &c., do not come under this heading.

It will be seen that, as far as the information obtained shows, only two metals disobey the above rule, viz., zinc and gold. Zinc forms zincates, while zinc chloride combines with ammonia. Zincates decompose when their solutions are boiled, and the compound of zinc chloride with ammonia does not appear to be formed in solution; so that the metal seems to be on the borderland between the two classes, and is able to partake in a low degree of the properties of each.

Gold forms aurates, also "fulminating gold." This is considered by some to be the compound expressed by the formula (NH₄Au)Cl; others hold it to be ammonium aurate. As there appears to be an extremely explosive compound of the above formula, gold must be reckoned an exception to the rule. It may be said, however, that gold follows the law closely enough to render this substance exceedingly unstable.

CITY OF LONDON COLLEGE, WHITE STREET AND ROPEMAKER STREET, MOORFIELDS, E.C.

MICHAELMAS TERM commences OCTOBER 3rd.

CLASSES and LABORATORY WORK in CHEMISTRY, PHYSICS, BIOLOGY, BOTANY, GEOLOGY, and PHYSIOLOGY. Special preparation for the Examinations of the Pharmaceutical Society, The Conjoint Board, Complete Courses for University Matriculation and Inter, and Final B.Sc., meeting during the Evening and on Saturday.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

THE DURHAM COLLEGE OF SCIENCE, NEWCASTLE-UPON-TYNE.

Complete Courses of Instruction are provided for Students of both sexes proceeding to the University Degrees in Science, or in Letters, and for the University Diploma in Theory and Practice of Teaching. Special facilities are offered for the study of Agriculture, Applied Chemistry, Mining, and all branches of Engineering and Naval Architecture.

Matriculation and Exhibition Examinations begin September 26th. Lectures begin October 4th, 1904.

Prospectuses on application to the SECRETARY.

UNIVERSITY COLLEGE, BRISTOL. CHEMICAL DEPARTMENT.

Professor—MORRIS W. TRAVERS, D.Sc., F.R.S.
Assistant Professor—FRANCIS E. FRANCIS, D.Sc., Ph.D.
Lecturer—OLIVER C. M. DAVIS, B.Sc., A.I.C.
Lecture Assistant—J. H. STURGES.

THE SESSION 1904-5 begins on OCTOBER 4th. Lectures on Inorganic, Organic, and Advanced Chemistry will be delivered during the Session. The Laboratories are fitted with the most recent improvements for the study of Practical Chemistry and Metallurgy in all its branches. In the Evening the Laboratory is opened on Mondays, and Lectures on Inorganic Chemistry, at reduced fees, are delivered. Several Scholarships are tenable at the College.

CALENDAR, containing full information, price 1s. (by post, 1s. 4d.). For Prospectus and further particulars apply to—

JAMES RAFTER, Registrar and Secretary.

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

DEPARTMENTS OF CHEMISTRY, TECHNICAL CHEMISTRY, and METALLURGY.

Chemistry.. . . .	Prof. G. G. HENDERSON, M.A., D.Sc., F.I.C.
Technical Chemistry .. .	Prof. THOMAS GRAY, D.Sc., Ph.D.
Metallurgy	Prof. H. HUMBLDT SEXTON, F.C.S., F.I.C.

The Courses of Instruction in these Departments are arranged for Students preparing to become Manufacturing or Analytical Chemists, Metallurgists, or Science Teachers. The courses in Chemistry qualify for the Examinations of the Institute of Chemistry and of the Universities of Glasgow, Edinburgh, and London.

SESSION 1904-5 begins on TUESDAY, SEPTEMBER 27th; the ENTRANCE EXAMINATION begins on MONDAY, SEPTEMBER 19th.

CALENDAR (by post 1s. 4d.), containing regulations for the Association of the College, may be obtained from the SECRETARY, 38, Bath Street, Glasgow. PROSPECTUS free.

REDRUTH SCHOOL OF MINES, CORNWALL.

Session 1904-1905 begins September 7th.

A "Mining Certificate" is awarded to Students passing successfully through the School Course.

PRACTICAL MINING CLASSES, under the Instruction of Capt. WILLIAM HAMSLY (late Government Inspector, South Africa) Distinctions in Mine Surveying in Open Examination five years in succession, including five Medals and Prizes, being all the awards of the City and Guilds of London Institute in 1904 in this subject.

SYLLABUS and every information on application to—

THE REGISTRAR.

VOL. XC., No. 2336.

ON THE ABSORPTION OF GASES BY CHARCOAL AND COKE.

By G. CRAIG, F.I.C.

It is well known that coke occludes gases in quantity dependent upon its nature and the temperature of its formation. A sample of lignite coke occluded so much that some experiments were made to ascertain the nature of the gases occluded.

The lignite coke was non-vesicular, and was employed in pieces about the size of peas. The charge practically filled the bulb of Jena glass in which it was heated and which was provided with a gas tube and stopcock. After heating to redness, the stopcock was closed, and the bulb and contents allowed to become thoroughly cold. Communication was then made with a graduated vessel containing air, and the coke allowed to become saturated at the ordinary temperature.

By running in mercury the unabsorbed gas was expelled, and the occluded gases were expelled by heating, or more slowly by treating with water.

The unabsorbed gas was found to be nearly pure nitrogen, which suggested the likelihood of the occluded gas being highly oxygenated. On expelling it, however, it was found to be nitrogen also.

Thus, 30 grms. of the coke (=20 c.c. volume) absorbed 220 c.c. of air, and:—

	N.	O.	CO ₂
The unabsorbed gas consisted of ..	99.53	0.47	nil
Gas expelled at 100° C. ..	99.70	0.30	"
Gas expelled at 320° C. ..	95.15	3.64	1.21

Another experiment in which 10 grms. (treated in a much larger bulb) = 6.7 c.c. volume absorbed 140 c.c. of air, and:—

	N.	O.	CO ₂
The unabsorbed gas consisted of ..	87.8	12.2	nil
First portion liberated with water consisted of ..	93.86	6.14	"
Second portion liberated with water consisted of ..	96.00	4.00	"
Third portion liberated with water consisted of ..	98.44	1.56	"
Fourth portion liberated with water consisted of ..	100.00	nil	"

The oxygen absorbed had thus entirely disappeared, and as the coke contained no reduced metal to take it up, and there was practically no CO₂ formed, it must have combined with hydrogen in the coke to form water. Indeed, water was always found in the gas tube after each heating up.

An attempt was made to burn out the hydrogen by maintaining the coke at a dull red heat for some days with some access of air, but the coke thereafter gave the same occlusion results.

This extraordinary and easy oxidation at ordinary temperatures suggested that the lignite coke must present, as it were, a surface of hydrogen, and that in a galvanic couple it would act as a positive element to an ordinary battery carbon. This was found to be the case, and it was even positive to copper in a dilute H₂SO₄ solution.

In the highly interesting occlusion results obtained by Prof. Sir James Dewar at low temperatures with cocoanut charcoal (*vide* CHEMICAL NEWS, vol. xc., p. 73), the same oxidation of hydrogen must take place to some extent unless the sample contains no hydrogen at all. A suitable temperature would be temporarily attained while the gas

was rushing into the bulb and before a poor conductor of insulator like charcoal could prevent it. Such action might explain the observed liberation of more heat than is accounted for by the liquefaction of the gases containing oxygen, and possibly this secondary action might be eliminated by an extremely slow admission and absorption of the gas.

Chemical Laboratory, Glasgow.

SOME METHODS FOR THE DETECTION OF COBALT AND NICKEL.*

By STANLEY R. BENEDICT.

BECAUSE of the great similarity of chemical behaviour between cobalt and nickel, the detection of these two elements in the presence of each other, particularly of small amounts of either, is a problem which presents peculiar difficulties. Many solutions of this problem have been proposed.

For comparison with the methods I wish to propose, I mention what are, so far as I have been able to learn, the most delicate methods yet offered for the detection of cobalt and nickel when both are present in one solution. The one for the detection of cobalt was proposed by Vogel (*Ber.*, 1879, xii., 2314). A saturated solution of ammonium sulphocyanide is added, then a mixture of amyl alcohol and ether added, and the solution shaken. If cobalt be present, the alcohol-ether layer has a blue colour. This method is very sensitive, and will detect 0.5 per cent of cobalt in nickel solutions.

The detection of traces of nickel in an excess of cobalt is a more difficult problem. The most delicate method, up to the present time, is probably the one suggested by Parr (*Journ. Am. Chem. Soc.*, 1897, xix., 341), which depends upon the fact that freshly precipitated nickel hydroxide will liberate iodine from potassium iodide, while cobaltic hydroxide will not. The procedure is as follows:—Bromine water is added to the solution, which is then warmed, next an excess of sodium carbonate added, and the solution brought to boiling. Both the cobalt and nickel are oxidised and precipitated in the trivalent condition by this treatment. The precipitate is well washed upon a filter and hot potassium iodide poured upon it. Free iodine in the filtrate is evidence of the presence of nickel. This test is not as delicate as Vogel's method for cobalt, yet it will detect nickel in many commercial cobalt salts.

My work comprises two methods, one for the detection of nickel only, the other for the detection of both elements. The first of these, viz., for the detection of nickel only, depends upon the fact that if a mixture of nickelous hydroxide and cobaltic hydroxide be treated upon a filter with a cold saturated solution of oxalic acid, the cobalt dissolves to form a complex cobaltoxalate compound, which is only very slowly precipitated by sodium hydroxide, whereas the nickel dissolves as a nickelous compound. The procedure is as follows:—Treat the solution with an excess of sodium peroxide, and warm to boiling. This, as was mentioned by Kassner, oxidises the cobalt but not the nickel (*Arch. Pharm.*, 1894, ccxxii., 226—240). Filter, wash the precipitate until perfectly cold, and pour upon the filter a cold saturated solution of oxalic acid. Pour this through the filter two or three times. To the filtrate add a few drops of a dilute solution of potassium ferricyanide, and then a slight excess of sodium hydroxide. If nickel be present, it is oxidised by the ferricyanide, and a heavy black precipitate of nickelic hydroxide appears, or if only a small amount of nickel be present, the solution darkens considerably. This test is very delicate, detecting as small an amount of nickel as 2 per cent, with comparatively little trouble.

* Read before the Cincinnati Section of the American Chemical Society, February 10, 1901. From the *Journal of the American Chemical Society*, xxvii., No. 6.

Although nickel forms no compound corresponding to the cobaltioxalate compound mentioned above, it has nevertheless been found advisable to use such a reagent as sodium peroxide, which oxidises only cobalt in preference to bromine or chlorine water, which would oxidise both elements, because in the decomposition of the oxalic acid by nickelic hydroxide some of the cobalt salt is reduced to the bivalent condition.

It may be stated that the cobaltioxalate compound formed in this test is of some interest. It has never been formed in this way before, its only method of formation having been by electrolysis, and by leaving a mixture of cobalt hydroxide and potassium tetroxalate made up to a paste with water for a period of from fourteen to twenty-one days (Kehrmann, *Ber.*, 1886, xix., 3101; 1891, xxiv., 2324). It is a green compound, the aqueous solution resembling the solution of a nickel salt in colour. In a manner similar to that outlined above, I have been able to form some new complex salts of other metals, which will be described later.

The second method which I propose is one by means of which either or both elements can be detected, even if one be in great excess, by a single operation in a test-tube. The procedure is extremely simple. It consists in adding an excess of 5N sodium hydroxide (ordinary reagent strength) to the solution, and agitating for half a minute. The results depend upon these facts. If sodium hydroxide be added in excess to a cobalt solution, a dark blue precipitate is at first formed, which is usually regarded as a basic salt. If nickel be entirely absent, this salt changes almost instantaneously to a bright pink compound, viz., the normal cobaltous hydroxide. If, however, nickel is present, this change of colour is retarded, the length of time increasing with the amount of nickel present. As will be seen, this test is extremely rapid, yet its rapidity is fully equalled by its delicacy. If sodium hydroxide be added in excess to each of two cobalt salts, one being an ordinary C. P. salt, and the other a sample of Kahlbaum's "nickel-free" cobalt, a decided difference in the length of time required for the change of colour is evident. In testing for traces of nickel, it is well to have a check tube containing a nickel-free sample for comparison. In this way mere traces of nickel can be detected. In fact, there is every reason to believe that this is the most delicate method so far proposed for the detection of nickel, as well as the most rapid. Its delicacy considerably exceeds that of the potassium iodide test outlined above, as has been determined by making comparative tests. In 10 c.c. of normal cobalt solution containing 1 per cent of nickel solution, the potassium iodide fails absolutely to reveal the presence of nickel, whereas the test outlined above will, in the same strength of solution, detect 0.5 per cent of nickel, and if the amount of cobalt be increased without decreasing the actual amount of nickel, 0.3 per cent of this element can be detected.

The question naturally arises why nickel in such minute quantities retards the change of the blue basic salt to the pink normal hydroxide. This is evidently difficult to answer, and the explanation put forth below is merely offered as a possible one.

This explanation is that when the basic salt, which would have some such formula as $\text{Co}(\text{OH})\text{NO}_3$, loses its NO_3 and begins to take up another OH radical, i.e., becomes, so to speak, nascent, the nickel combines with it to form a nickel cobaltite, which is even more blue than the basic salt. Then, as more of the basic salt changes over, the nickel is finally all taken up, the normal cobaltous hydroxide begins to form, and when a sufficient quantity of this has been formed to hide the blue of the nickel cobaltite, the pink colour makes its appearance. It may also be that the nickel cobaltite is formed immediately upon precipitation, and being unstable, soon breaks up, forming the hydroxides of the two metals.

The reasons for suggesting the formation of nickel cobaltite are as follows:—Firstly, the nickel produces an effect which cannot be accounted for by the physical pro-

perties of its hydroxide; secondly, cobalt is shown to form some cobaltites by the following facts:—(1) The hydroxide is somewhat soluble in a concentrated solution of potassium hydroxide, forming a dark blue solution. I have found that the hydroxide is also considerably soluble (upon warming) in a 5N sodium hydroxide solution in the presence of considerable quantities of salts of some other metals, among which are aluminum, lead, sodium, and lithium. (2) The solutions of these cobaltites are intensely blue, much more so than the original basic salt, a very small amount of cobalt in solution sufficing to give a very intense blue colour. It is therefore possible, if not probable, that the formation of a corresponding nickel compound, which is insoluble and deep blue in colour, may be the cause of the interference with the change of colour of the cobalt precipitate.

As was mentioned, the presence of very small amounts of cobalt can be detected by this method in presence of an excess of nickel. This test depends upon the formation of the blue compound mentioned above, and on the further fact that this colour makes itself evident in a great excess of nickel. For this reason, when sodium hydroxide is added to a solution which contains nickel in excess, if cobalt is present (even somewhat under 1 per cent), this blue colour makes itself visible, especially upon standing a moment, i.e., the hydroxide, instead of being a pure pale green, will have a bluish tinge, more or less deep, depending upon the amount of cobalt present.

In a test of this delicacy it is only natural that certain conditions must be fulfilled lest the results lead to incorrect conclusions. These conditions are as follows:—

1. Other metals besides nickel and cobalt should be absent, since many of these interfere with, or give the reaction outlined above. This is easily accomplished by following the ordinary course of analysis.

2. The solution in which the test is made should be roughly normal (or somewhat stronger) in order that the colour reactions may be best observed.

3. The solution should not contain much free acid (a small amount makes no difference), since the salt formed upon the addition of the hydroxide may interfere somewhat, because, as was mentioned above, the salts of the alkali metals tend to form cobaltites.

The procedure for the detection of the two metals is therefore as follows:—Dissolve the sulphides in concentrated nitric acid, evaporate to dryness, heat gently to expel free acid, and dissolve in a little water. To about 3 c.c. of this solution in a test-tube add 6 to 8 c.c. of sodium hydroxide, cover the mouth of the test-tube with the thumb, mix thoroughly by shaking, and note the result. If cobalt be in excess, the precipitate will have a dark blue colour; if nickel be present in very small amount, the colour will not change immediately, i.e., within four to five seconds, to a bright pink. If, however, the nickel be present in large amount, the change of colour will be retarded for half-an-hour or more, the colour never becoming a bright pink, but changing to a dirty grey. If nickel be absent, the change of colour is practically instantaneous.

If nickel be in excess, the precipitate will not be dark blue, but will have a green colour, which will show more or less bluish tinge, depending upon the amount of cobalt present. If cobalt be absent, the precipitate will be a pale green, and will remain so upon standing.

It will therefore be evident that by this test, which is practically instantaneous and requires no manipulation, it is possible in one operation, carried on in a test-tube, to detect both elements, even if either element be in exceedingly small amount, in a great excess of the other, the test for cobalt being probably as delicate as any hitherto proposed (with the exception of Vogel's test, outlined above, which requires the use of ammonium sulphocyanide, amyl alcohol, and ether), while that for the detection of nickel is considerably more delicate than anything hitherto proposed for this purpose.

For use in ordinary qualitative analysis in college

laboratories where nickel-free cobalt salts are not supplied to students, the test may be modified in one of two ways in order to slightly decrease its delicacy. (1) The students may be told that unless the change of colour is retarded over a minute, nickel may be regarded as absent, or (2) by using, instead of a 5N sodium hydroxide solution, a 10N or 15N solution, when the delicacy is so decreased as to give practically no reaction for nickel in ordinary cobalt salt solutions.

I desire to express my sincere thanks to Dr. J. F. Snell for the valuable advice he has rendered during the progress of this work.

ESTIMATION OF TANNIC AND GALLIC ACIDS.

By W. P. DREAPER, F.I.C., &c.

A RECENT paper on this subject by Messrs. Parker and Payne (*Journ. Soc. Chem. Industry*, 1904, p. 648), recommending the separation of tannic acid as the calcium salt, leads me to think that some further experiments made with the process I brought forward in 1893 may be of value at the present juncture (*Journ. Soc. Chem. Industry*, May, 1893).

In my original process, the tannic and gallic acids were precipitated as lime (or barium) salts, with subsequent titration with copper sulphate solution. The lime method is preferable to the barium one.

The results were expressed in terms of CuO instead of CaO, as in Parker and Payne's process.

In the discussion following one of Dr. Parker's papers at Burlington House, I protested against the leather people setting up a standard for the analysis of tannin materials without reference in any way to the requirements of other trades. Their standard was of such an empirical nature that general chemists could not be expected to accept it.

Even those working in allied industries, such, for instance, as that of dyeing, could hardly be expected to do so.

From this point of view, a process based on the formation of a definite metallic compound is certainly an advance in the right direction, although this idea is, of course, not a new one.

My experiments during the last five years lead me to think that Dr. Parker's statement, that his process agrees in its results with the hide-powder process, is sufficient evidence that it is an unsatisfactory one, and that he is estimating gallic, and perhaps other obscure acids, as tannic acids.

This seems to be the necessary result of using a colloid precipitant. My contention is that such reagents must give way, as the alkaloids have, and that only by a close study of the conditions of precipitation, as metallic salts, can we ever advance in our knowledge of this intricate subject.

For example, the following figures show the percentage of tannic acid (?) in pure gallic acid, as estimated by my improved method and the hide-powder process. The latter is taken as a typical colloid precipitant:—

Dreaper method	0.0 per cent tannic acid.
Dreaper method (but with hide-powder separation)	45.6 " "
Hide-powder process	27.0 " "

As this acid was quite free from tannic acid, these figures are interesting!

The 27.0 per cent error in the case of hide-powder as against the 45.6 per cent error, when copper titration takes the place of the usual weighing of the residue, was at first sight puzzling, but it was found that another serious error (amounting to 18.6 per cent) compensated for that excess in the latter case. This second error was due to the solvent action of the solution on the hide-powder.

What can we say for such a process giving such results as this?

The improved process is put forward, not because it is considered a perfect one, but because it is at least capable of indicating errors of the above order in the hide-powder process. It also indicates a possible way of separating tannic acids into what we regard as their two natural orders, and estimating the gallic acid present at the same time.

By some such comparison as the above we may be able to find out—and possibly eliminate—the errors of known processes.

My modified method requires the following standard solutions:—

1. Standard copper sulphate solution, = 0.05 CuO per c.c.
2. Fifty grms. Am_2CO_3 and 50 grms. sodium sulphite per litre.
3. Twenty grms. lead acetate and 60 c.c. glacial acetic acid per litre.

Fifty c.c. of the original solution, containing from 10 to 15 grms. per litre of tannin material, is titrated with the copper solution after heating with excess of CaCO_3 and cooling. The result, expressed as CuO, represents the total tannic and gallic acids, and from the dyers' point of view the "mordant value" of the extract.

Ferrocyanide indicator is used. A drop of the tannin solution is taken up on a glass rod and pressed on to a doubled sheet of filter-paper. The clear solution on the under sheet is tested with the indicator. One of the best papers to use is brand C. S. and S., No. 589, No. 3. A good paper is necessary.

A second 50 c.c. of tannin solution is taken, and 25 c.c. of No. 2 added. Copper tannate formed on titrating this solution is free from gallate. Towards the end of the reaction the copper salt is precipitated slowly, and two or three minutes must elapse before the final colour reaction is taken. The ferrocyanide solution must be rendered strongly acid with acetic acid.

The process breaks down in the absence of the sulphite, which seems to prevent oxidation. In the case of an unknown extract, the precipitate may be filtered off and weighed at 105°. From this the tannic acid present may be easily calculated, the amount of CuO present being known.

Fifty c.c. are again taken, and 10 c.c. of the lead solution added in the presence of barium sulphate. Shake well, and filter off through dry filter-paper, add a small amount of anhydrous sodium sulphate to the filtrate to remove lead. After five minutes pass through another dry filter-paper. Forty c.c. of this is taken, heated with CaCO_3 , and titrated as in No. 1.

This gives the gallic acid in filtrate, and, by difference, the total tannic acid. This figure will, or will not, agree with No. 2 as the case may be. This will afford a means of estimating the tannic acids (soluble or insoluble) in the ammoniacal solution. This classification is recognised, and this is the only method of separating these two groups quantitatively that the author knows of.

The double filtration to remove the tannate of lead and the excess of sulphate is necessary, as lead sulphate is soluble in calcium acetate solution. The different colours obtained by the ammoniacal titration seem, in some cases, to afford an indication as to their origin. They vary from apple-green to brown through yellowish shades.

It will not do to add the Na_2SO_4 to the solution containing the precipitated tannate. In that case the tannic acid goes into solution. It will be noticed that the difficulty in preventing the decomposition of the lead salt in washing is also obviated.

The following figures working on a pure commercial tannic acid are interesting. (See Table, next column).

The result quoted for gallic acid by the hide-powder process will be noted, because it has been said that one error in this process is due to the absorption of other acids by the hide-powder. These experiments show how useless a blank experiment with distilled water may be.

Acid taken.	Method of separation.	Tannic acid in terms of CuO. Gm.
0.25 grm. tannic acid	.. { Amm. copper	0.083
	.. { Pb method	0.083
0.25 grm. tannic acid + 0.1 grm. gallic acid	.. { Amm. copper	0.084
	.. { Pb method	0.082
0.25 grm. gallic acid	.. { Amm. copper	0.000
	.. { Pb method	0.000

Ammonium carbonate is preferred, although the hydrate will answer. Parker and Payne's experiences with lead nitrate are confirmed by the author. The lead solution recommended above is found to be sufficiently acid to prevent the precipitation of gallic acid. Lead nitrate is more satisfactory for the precipitation of tannic and gallic acids in the presence of sodium acetate.

A single test made on a solution containing equal parts of tannic and gallic acids indicates that about 60 per cent of the gallic acid was carried down with the tannin-collin compound. It is this "carrying down" property of the colloids which is so unsatisfactory. One can never be certain what they will take down with them or subsequently absorb. This seems to be a property common to all the colloids in the insoluble state. The solution after filtering was fairly free from tannic acid. It gave a slight precipitation with the lead acetate solution, but about 98 per cent of the tannic acid present was precipitated. Unfortunately 60 per cent of the gallic acid came down as well. This does not indicate that collin is a satisfactory precipitant.

If collin, in spite of its physical properties, is only a pure gelatin, as Messrs. Parker and Payne assume, it is difficult to see in what way it is superior to the older colloids.

Also, it is probable that the acetic acid added in measured quantity may be under the influence of the precipitated colloids. It is known that some of these bodies have the greatest affinity for such acids. It remains to be seen whether collin acts in the same way.

It is unfortunate, too, that any substance capable of combining with or neutralising $\text{Ca}(\text{HO})_2$ will be returned in the estimation as tannin material. Precipitating as calcium tannate and titration with copper solution gets over this difficulty. Soluble salts would not be estimated.

The direct lime process does not seem to have any advantage over my indirect one. In fact, the opposite seems to be the case when the colloid separation is used. On pure materials, the copper salts agree with the theoretical requirements. The crux of the whole position is the necessity for an efficient precipitating process for the tannic acid.

The lead and copper ammonium separating processes given above are, I believe, far in advance of any colloid method. Whether they are perfect remains to be seen, but they at least open out a new line for work; they separate quantitatively the tannic acids into two classes in a way never before attempted.

It is difficult to see, however, how either calcium or barium hydrate can be used with them. Copper sulphate solution, however, seems to work well.

The colour test put forward as such a feature of the new Parker and Payne process is not new. It is already in everyday use (Proctor, "Leather Industries Lab. Book," p. 88).

It is interesting to note also that Darton's gravimetric estimation works more satisfactorily in the presence of sodium sulphite. With digallic acid the results obtained agree with the theoretical figures. The excess of copper salt present in the solution should be small. The correct amount may be indicated by a preliminary trial as above, and the percentage of copper present in the resulting precipitate estimated at the same time.

The writer considers that the above results may be of interest at the present time. The subject has been approached from quite a different standpoint to that of the leather expert, and different results have been obtained. In the absence of definite and extended

results, collin is regarded with great suspicion as a precipitant by the author. Figures will have to be brought forward to show what its action is on solutions of pure tannic acid containing other acids before any reliance can be placed on it. Does collin differentiate between tannic acid and other organic acids in mixtures of the same? If not, the process stands just where the hide-powder process does to-day, and another series of international conferences will be necessary to deal with this new precipitant.

THE NATURE OF THE PRINCIPAL PHOSPHORUS COMPOUND IN WHEAT BRAN.*

By A. J. PATTEN and E. B. HART.

SUMMARY.

1. PRACTICALLY all of the soluble phosphorus of wheat bran is of an organic nature.

2. The organic compound exists in the bran itself as a magnesium-calcium potassium salt of a phospho-organic acid.

3. The free acid corresponds to the formula $\text{C}_2\text{H}_8\text{P}_2\text{O}_9$, and is probably identical with Posternak's anhydro-oxy-methylene diphosphoric acid.

4. The alkali salts of this acid are freely soluble in water. The calcium and copper salts are slightly soluble, while the barium and strontium salts are but sparingly so.

5. The acid and its salts seem to be of wide distribution in the vegetable kingdom, having already been isolated from the seeds of red fir, peas, beans, pumpkin, red and yellow lupine, also from the potato and other tubers and bulbs.

This investigation forms part of the research on the metabolism of phosphorus and sulphur in the animal body conducted under the direction of Dr. Jordan. The physiological rôle of the acids and its salts in animal metabolism will be made the subject of future researches.

INTRODUCTION.

From the work reported in *Bulletin* No. 238 of this Station, and from other work done preliminary to an investigation of the metabolism of phosphorus in animals, it was found that in many of our ordinary feeding stuffs a varying percentage of the organic phosphorus is directly soluble in water and in dilute hydrochloric acid. Data illustrating this point will be found in the following table:—

TABLE I.—Soluble Phosphorus in Oats, Malt Sprouts, and Wheat Bran.

	Total phosphorus. Per cent.	Solvent.	Soluble phosphorus. Per cent.	Percentage of total phosphorus. Per cent.
Oats	0.355	{ Water	0.180	50.0
		{ Hydrochloric	0.096	27.0
Malt sprouts	0.677	{ Water	0.548	81.0
		{ Hydrochloric	0.477	70.0
Wheat bran	1.22	{ Water	1.056	86.5
		{ Hydrochloric	0.95	77.8

It will be seen that wheat bran carries a much larger percentage of phosphorus than any of the others, and that 86.5 per cent is soluble in water.

It was at first supposed that the soluble phosphorus was in combination as nucleins or salts of nucleic acid, but determinations of the amount of soluble nitrogen showed that only about 33 per cent of the phosphorus could be accounted for in this way.

We were therefore led to the conclusion that by far the greater part of the soluble phosphorus was linked up in some other organic combination, since Hart and Andrews have shown that the amount of soluble inorganic phos-

* *Bulletin* No. 250, New York Agricultural Experiment Station.

phorus is exceedingly small (*Bulletin* No. 238, N. Y. Agr. Expt. Station).

INVESTIGATION OF PHOSPHORUS COMPOUND. Attempt to Isolate.

Two pounds of wheat bran was extracted with 6 litres of 0.2 per cent hydrochloric acid for several hours with frequent stirring. The extract was strained through cheese-cloth, and finally filtered through paper.

The filtrate was treated with a large volume of 95 per cent alcohol, which threw down a voluminous, flocculent precipitate. The precipitate was allowed to settle to the bottom, the supernatant liquid syphoned off, and the precipitate washed with alcohol several times by decantation. It was then dissolved in a small volume of 0.2 per cent hydrochloric acid, filtered from an insoluble residue, re-precipitated by alcohol, and washed as before by decantation.

This process was again repeated, the precipitate finally brought upon a filter, washed with absolute alcohol and ether, and dried at 110° C. The resulting product, which weighed 7.2 grms., was a white amorphous powder readily soluble in water.

Its water solution was acid to litmus, and it was precipitated from such solution by solutions of salts of the heavy metals, by the alkali metals and the alkaline earths, also by alcohol and ether.

Chemical analysis showed it to be an organic phosphorus compound coupled with calcium, magnesium, and potassium.

Of this substance:—

0.5004 gm. gave 0.0082 gm. CaO and 0.1327 gm. $Mg_2P_2O_7$, equivalent to 1.13 per cent Ca and 5.80 per cent Mg.

0.512 gm. substance gave 0.0834 gm. K_2PtCl_6 , equivalent to 2.60 per cent K.

0.2174 gm. substance gave 0.1280 gm. $Mg_2P_2O_7$, equivalent to 16.38 per cent P.

0.2122 gm. substance gave 0.1438 gm. CO_2 and 0.072 gm. H_2O , equal to 18.52 per cent C and 3.83 per cent H.

The substance carried also a small amount of nitrogen (0.37 per cent), but this was considered an impurity, and, calculated as a proteid, would lower the carbon and hydrogen to 17.30 per cent and 3.63 per cent respectively.

Similar Compounds Reported by other Workers.

Palladin, working in Schulze's laboratory, isolated from the seeds of black mustard (*Sinapis nigra*) a highly phosphorised compound in combination with calcium and magnesium ("Beiträge zur Kenntniss pflanzlicher Eiweissstoffe," *Zeit. f. Biologie*, Jahrgang 1894, p. 199).

The seeds freed from fat were extracted with 10 per cent sodium chloride solution, filtered, and the filtrate heated to about 80° C. A precipitate separated carrying with it all of the proteid. The larger part of the precipitate went into solution again on cooling, leaving the coagulated proteid in suspension, which was separated by filtration. The filtrate was again heated, and the resulting coagulum collected on a hot water funnel.

Schulze and Winterstein ("Ueber einen phosphorhaltigen Bestandtheil der Pflanzensamen," *Zeit. f. Physiol. Chem.*, xlii., 90) continued the investigation started by Palladin, and obtained a compound carrying 9.65 per cent C, 2.83 per cent H, and 16.13 per cent P. They thought the substance might be identical with the chief constituent of the globoids found enclosed in the protein kernel of many plant seeds. W. Pfeffer ("Untersuchung ueber die Pro-

teinkoerner und die Bedeutung des Asparagins beim Keimen der Samen," *Jahrbuch für Wissenschaftliche Botanik*, 1872, viii., 147) in conjunction with Brandau found that such globoids consist of a calcium-magnesium salt of an organic body coupled with phosphoric acid. What the nature of this organic combination was they were unable to say.

Winterstein isolated a compound from the seeds of black mustard by extracting with dilute acetic acid ("Ueber einen phosphorhaltigen Pflanzenbestandtheil welcher bei der Spaltung Inosit liefert," *Ber. d. Chem. Ges.*, 1890). The extract was freed from proteid by boiling and filtering when cold. The filtrate was made slightly alkaline with ammonium hydrate and boiled, the resulting precipitate collected on a hot water funnel, and washed with hot water until the wash water reacted neutral. The substance was purified by dissolving in dilute acetic acid, and re-precipitating with ammonium hydrate. On removing the calcium with oxalic acid, a product was obtained carrying 18.44 per cent P and 7.83 per cent Mg. By heating the magnesium salt in a closed tube with concentrated hydrochloric acid for thirty hours, at a temperature of 130–140° he obtained inosite as a cleavage product.

The compound obtained by us from bran by the alcohol method, though still impure, is undoubtedly identical with the one described by these investigators.

Posternak isolated the compound from the seeds of red fir, pumpkin, peas, beans, white and yellow lupine, and also from the potato (*Revue Generale de Botanique*, 1900, xii., 5 and 65; *Comptes Rendus*, cxxvii., Nos. 3, 5, 8). He also isolated and identified the free acid as anhydrous oxymethylene diphosphoric acid with the following formula:

The method adopted by Posternak was the following:—

The material was extracted with dilute hydrochloric acid and filtered, the filtrate was made alkaline with sodium hydrate, and precipitated with calcium chloride. The calcium chloride precipitate was filtered, washed, and finally dissolved in dilute hydrochloric acid. Sodium acetate was added to the solution to replace the free mineral acid by acetic acid, and copper acetate added in excess. The copper precipitate was filtered, thoroughly washed with water, and decomposed by hydrogen sulphide.

The copper sulphide was removed by filtration, and the excess of hydrogen sulphide removed by pumping air through the liquid. It was then evaporated in a vacuum over sulphuric acid.

We found it very difficult to remove the last traces of calcium by this method, and have modified it by substituting barium chloride for calcium chloride. This admits of a very thorough washing at this stage of the operation, as the barium salt is much more insoluble than the calcium salt, and also admits of a complete removal of the barium as a sulphate.

Method of Preparation of Free Acid.

The method finally adopted by us is as follows:—

The bran was extracted with 0.2 per cent hydrochloric acid, strained through cheese-cloth, and filtered through paper. Since the compound is present in bran as a calcium-magnesium potassium salt, it was precipitated directly with copper acetate, by which means we were able to remove the greater part of these bases. After washing the copper precipitate it was suspended in water, and decomposed by hydrogen sulphide. The filtrate from copper sulphide was made alkaline with sodium hydrate, and precipitated with barium chloride. The barium salt was washed until free from alkali, suspended in water, and dilute sulphuric acid added in sufficient quantity to decompose the salt and throw down the barium as a sulphate. After removal of the barium sulphate by filtration the

filtrate was again precipitated in alkaline solution with barium chloride, and treated as before. This process was repeated a third time, and after final removal of the barium, copper acetate was added in excess. The copper precipitate was filtered at the pump, thoroughly washed with water, and finally suspended in water and decomposed by hydrogen sulphide. The copper sulphide was removed by filtration, and the filtrate evaporated on the water-bath to a syrupy consistency.

Analysis of the acid dried at 110° gave the following results:—

0.7207 grm. substance gave 0.2811 grm. CO_2 and 0.2202 grm. H_2O , equivalent to 10.63 per cent C and 3.38 per cent H.

0.1039 grm. substance gave 0.097 grm. $\text{Mg}_2\text{P}_2\text{O}_7$, equivalent to 25.98 per cent P.

	Found.	Calculated for $\text{C}_2\text{H}_6\text{P}_2\text{O}_8$.

P	25.98	26.07

Decomposition of Compound into Inosite and Phosphoric Acid.

Heated with concentrated mineral acids it is broken up quantitatively into inosite and phosphoric acid, after the following equation:—

Posternak obtained 97.8 per cent of the total carbon of the acid decomposed as inosite. In our investigation an unweighed portion of the acid was heated in a closed tube with 50 c.c. of 30 per cent sulphuric acid at a temperature of 155 – 160° for five hours. After cooling, the tube was opened, and the contents washed into a beaker. The sulphuric and phosphoric acids were removed by barium hydrate, and the excess of barium by carbon dioxide. The filtrate was evaporated nearly to dryness, taken up with hot water, and filtered from remaining barium carbonate. The filtrate was then treated with absolute alcohol and ether until a cloudiness was produced, when it was allowed to stand in the cold. A crystalline precipitate soon separated, which was obtained pure after once re-crystallising. It gave the reactions of Scherer and Gallois, and melted at 218 – 219° (uncor.). Inosite melts at 218° (uncor.).

Carbon and hydrogen determinations were made on the substance dried at 110° .

	Found.	Calculated for inosite. $\text{C}_6\text{H}_{12}\text{O}_6$.

Properties of Anhydro-oxymethylene Diphosphoric Acid.

The free acid dried slowly over sulphuric acid is a very thick transparent liquid of a yellowish brown colour. It is soluble in all proportions in water and alcohol, insoluble in ether, benzene, chloroform, and glacial acetic acid. It has a very sharp acid taste. Heated to 110° it becomes decidedly brown without decomposition. The alkali salts of the acid are freely soluble in water. Water solutions of the free acid are precipitated by ferric chloride, the precipitate being soluble in an excess of the reagent. Silver nitrate precipitates solutions of the free acid only after a liberal excess of the reagent has been added. The precipitate is insoluble in excess of the reagent. The free acid is not precipitated by the chlorides of magnesium, calcium, barium, or strontium, due to the liberation of free hydrochloric acid. However, when solutions of the alkaline salts of the free acid are treated with the above reagents, a precipitate is formed.

The magnesium and calcium salts are somewhat soluble in water, the barium and strontium salts very sparingly soluble. The magnesium salt is easily soluble in acetic acid, the calcium salt less so, while the barium and strontium salts are very insoluble. All are readily soluble in mineral acids.

The free acid is tetra-basic and forms two salts, the one a normal salt, the other an acid salt. The normal salt reacts neutral to phenolphthalein, while the acid salt reacts neutral to methyl-orange, which may be shown by the following determinations:—Ten c.c. of a solution containing 0.0648 grm. of the acid titrated to phenolphthalein with decinormal barium hydrate required 10.9 c.c. or 0.0748 grm. barium. 0.0648 grm. of the acid should require 0.0749 grm. barium to produce the normal salt ($\text{C}_2\text{H}_4\text{P}_2\text{O}_8\text{Ba}_2$). Ten c.c. of the same solution titrated to methyl-orange with decinormal barium hydrate required 5.1 c.c. or 0.035 grm. barium. 0.0648 grm. of the acid should require 0.0343 grm. barium to produce the acid salt ($\text{C}_2\text{H}_6\text{P}_2\text{O}_8\text{Ba}$).

Quantitative Estimation of the Acid in Wheat Bran.

We extracted 10 grms. of bran to 500 c.c. with 0.2 per cent hydrochloric acid, made 100 c.c. alkaline with sodium hydrate, precipitated with barium chloride, filtered, and washed free from alkali.

The phosphorus was determined directly in this precipitate.

	Per cent.
Total phosphorus	1.35
Phosphorus in barium precipitate	0.92
Per cent of phosphorus in barium precipitate to total phosphorus	68.1

Practically all of the phosphorus soluble in 0.2 per cent hydrochloric acid is in this form, as is shown below:—

	Per cent.
Total soluble phosphorus	0.94
Phosphorus in barium precipitate	0.92
Per cent of phosphorus in barium precipitate to total soluble phosphorus	97.9

A DETERMINATION OF NITRITES IN ABSENCE OF AIR.*

By I. K. PHELPS.

DUNSTAN and Dymond have recommended the use of an evacuated flask for the estimation of nitrites by the action of potassium iodide in acid solution (*Pharm. Journ.*, [3], xix., 741). Under these conditions, the nitrous and hydriodic acids interact to produce nitric oxide (which must be kept from contact with gaseous oxygen) and iodine which is determined by decinormal solution thiosulphate. As objections to the process may be cited, the necessity of getting an absolutely gas-tight rubber-jointed apparatus, and the restriction put upon the size of the flask by the two considerations of withstanding the atmospheric pressure when evacuated, and yet being thin-walled enough to allow of the ready heating of the flask. A practical test of a slight modification of the device already used in the determination of nitric acid for getting an inert atmosphere proves to obviate these difficulties and to leave little to be desired in point of accuracy (*Am. Journ. Sci.*, 1902, xiv., 440).

The apparatus used was the same as in the estimation of nitric acid referred to above. It consisted of a boiling flask of 250 c.m.³ capacity closed with a rubber stopper carrying in its two perforations the inlet and exit tubes. A stoppered funnel of 50 c.m.³ capacity with its tube constricted at its lower end was used as an inlet tube, and a glass tube of 0.8 c.m.³ internal diameter, enlarged just above the stopper to a small bulb (to prevent mechanical loss of the solid contents of the flask during the boiling), and bent twice at right angles, served as an exit tube. The flask was supported in the usual manner at a convenient height to allow of heating with a Bunsen burner placed beneath, and the

* Contributions from the Kent Chemical Laboratory of Yale University. From the *American Journal of Science*, [4], xvii., No. 99.

exit tube was made of a sufficient length to reach to the surface of some mercury contained in a test-tube to the depth of about 3 centimetres.

The analysis was made as follows:—An amount of standard arsenious acid solution, slightly in excess of that required to take up the iodine to be set free later by the nitrous acid, and 25 c.m.³ of a concentrated solution of sodium carbonate were placed in the flask. The stem of the dropping funnel was completely filled with water, the rubber stopper inserted tightly, and the contents of the flask boiled until all air was expelled—a process requiring an active boiling of five to eight minutes. The flame was then removed, the exit tube plunged deep into the mercury by changing the position of the flask on its wire-gauze—which is particularly easy if the gauze is well depressed at the centre, and the flask placed well up on the higher part in the preceding operation—and sulphuric acid (1—4) sucked in through the funnel tube as the flask cooled, the cooling to the room temperature being hastened by standing the flask in a dish containing ice and water. In all, 7 c.m.³ of sulphuric acid were added, this amount having been found by previous experiment to be nearly but not quite enough to neutralise the sodium carbonate used, and also having been found to yield a little more carbon dioxide than the apparatus can hold at the atmospheric pressure. As soon as the diminished pressure in the apparatus was too weak to suck in the acid, the position of the flask was again changed on the wire-gauze, so that the exit tube was raised out of the mercury into the layer of water which had condensed during the preceding boiling, and which then served to trap the apparatus from the outside air. After the acid had been added and had been washed in carefully, the nitrite solution to be analysed containing 2 grms. of pure potassium iodine was introduced into the flask through the funnel, and this was followed by sulphuric acid (1—4) in sufficient amount (5 c.m.³) to render the contents of the flask acid in reaction. Potassium bicarbonate was then added in concentrated solution to alkaline reaction, or until the free iodine had been taken up, the mixture boiled for about five minutes to expel the nitrogen dioxide, cooled, and titrated to colour with decinormal iodine in the presence of starch paste. In making the various additions of liquid to the flask, care was necessarily taken that no air was introduced with the liquid. Table I. records experiments made in this manner upon a solution of commercial sodium nitrite, standardised by treatment with potassium permanganate and oxalic acid in acid solution according to the procedure of Kinnicutt and Nef (*Am. Chem. Journ.*, 1883, v., 388).

TABLE I.

NaNO ₂ taken.	Oxygen value of As ₂ O ₃ taken.	Oxygen value of As ₂ O ₃ found.	Error on oxygen.	Error on NaNO ₂ .
Grm.	Grm.	Grm.	Grm.	Grm.
1. 0.0058	0.01200	0.00061	0.00025+	0.0011+
2. 0.0093	0.01200	0.00066	0.00021+	0.0010+
3. 0.0116	0.03200	0.00065	0.00017+	0.0007+
4. 0.0116	0.03200	0.00065	0.00017+	0.0007+
5. 0.3832	0.05600	0.01120	0.00043+	0.0018+
6. 0.3832	0.05600	0.01118	0.00045+	0.0019+
7. 0.6716	0.08000	0.00160	0.00076+	0.0033+
8. 0.6716	0.08000	0.00158	0.00078+	0.0034+
9. 0.0196	0.03280	0.01003	0.00062+	0.0027+

The experiment numbered 9 is included to show a fact found early in the investigation, namely, the necessity of boiling out the nitrogen dioxide before titrating the residual arsenious acid. It was made like 3 and 4 above up to that point, when instead of boiling out the nitrogen dioxide, cooling, and titrating, it was treated with a slow stream of air bubbling through for fifteen minutes, and then titrated. Evidently the nitrogen dioxide in oxidising affects the arsenious acid slightly.

When the sulphuric acid is being added to the alkaline solution containing the arsenite, iodide, and nitrite, iodine

is set free locally, but it is at once taken up by the alkaline arsenite, so that finally, when the acid reaction is reached, there is only a small amount of it free, no matter how much nitrite may have been used. This condition reduces to a minimum the possibility of a loss of iodine by volatilisation.

As might be anticipated, the two processes show slightly different results, the process outlined above tending to give results in excess of the theory on account of the action of dissolved oxygen, while that of Kinnicutt and Nef should show a deficiency as compared with theory, since the loss of nitrogen oxides is evidenced by the odour when even a very dilute solution of a nitrite is acidified.

NOTICES OF BOOKS.

Gas Works, their Construction and Arrangement, and the Manufacture and Distribution of Coal-gas. Originally written by SAMUEL HUGHES, C.E. Ninth Edition, Revised, with Notices of Recent Improvements, by HENRY O'CONNOR, Assoc.M.I.C.E. London: Crosby Lockwood and Son. 1904. Pp. 416.

WHILE the general outline of this well-known book has been followed, all out of date references have been eliminated, and the latest methods only described. Reference is made to all recent processes used in gas manufacture, such as "carburetted water-gas," "acetylene gas," "Mond gas," &c., and descriptions of all new apparatus are given.

The book is divided into twenty-five chapters, commencing with a historical sketch of gas making, but we need not dwell on the early chapters, as this work, though in its unrevised form, has been a standard work for many years, and is thoroughly known to all gas makers.

In Chapter XIX. we come to an important question in gas making, viz., the various applications of gas for heating, cooking, and other purposes. Owing to the increasing competition of electric lighting, gas makers have had to look in other directions in order to keep up their turnover. Other methods of producing light, such as "water-gas," are described in Chapter XXI., and in Chapter XXII. the various controlling influences which affect the quality and volume of gas are discussed. Mond gas for power purposes is discussed on page 403 (Chapter XXIV.); and in Chapter XXV. the "sliding scale" first proposed by Mr. George Livesey is described. This method, combined with the bonus system of encouraging the workmen to do their best, has had very good results in London.

The book is well arranged and written, and will certainly hold its place as the book for students of gas engineering and gas makers.

There is a good index.

Gold Assaying; a Practical Handbook. By H. JOSHUA PHILLIPS, F.I.C., F.C.S., &c. With numerous illustrations. London: Crosby Lockwood and Son. 1904. Pp. 138.

Most books on metallurgy devote a chapter or two to gold assaying, but we do not at the moment remember a handbook devoted entirely to this subject; there are, of course, text-books dealing with the whole subject of gold, its prospecting, mining, washing, extraction, &c., but a practical handbook such as the one now before us is decidedly an acquisition. It gives the *modus operandi* for the accurate assay of auriferous ores and bullion, and the chemical tests required in the processes of extraction by amalgamation, cyanidation, and chlorination.

We think it would have been an advantage if the sections into which this book is divided had been numbered chapters, but that is a mere detail. The first section deals with the natural occurrence and forms of gold, and the origin of gold deposits; the physical and chemical properties of gold are next considered, followed

by the very important operation of sampling. Then we come to the assay itself, fusing, cupellation, scorification, parting, &c., and the assay of bullion. With regard to cupellation, we do not find any mention of magnesia cupels; these have been recommended by some practical assayers as preferable to the older ones of bone-ash for some purposes; it would be interesting and important to hear some authoritative opinions as to their respective merits.

The last section is on assays in cyanidation, chlorination, and amalgamation processes, together with a synopsis of each of these processes.

The appendix contains a number of useful tables, among which we may call attention to those giving the relative values and names of the weights, measures, and coins used in the principal countries.

The book is well arranged and written, while the illustrations are good and modern. We recommend this book both to beginners and to those in practice who may need occasionally to refer to it on some point.

There is an adequate index.

Analytical Chemistry. By F. P. TREADWELL, Ph.D.

Translated from the Second German Edition by WILLIAM T. HALL, S.B. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

The translator of this work has had the advantage of receiving help and criticism from many brother chemists, besides suggestions from the author as to the proposed alterations in the third German edition, so that the translation presents a good many advantages over the original. It is specially good as regards methods of separation of the less common elements. Gravimetric methods occupy more than half the volume, which would probably be more convenient for use and reference if all the various methods of determining each element, of which a great number applicable in slightly different circumstances are given, were collected together and not given in different parts of the book under the headings of gravimetric and volumetric analysis. Moreover, even this division is not strictly preserved; for instance, the determination of iron by titration is included under gravimetric methods. One very good feature of the book is the recognition of the value of electrolysis for quantitative work; its comparative simplicity of manipulation and convenience well qualify it for the important place the author accords it among other methods of determination.

Chemisch-technische Untersuchungsmethoden. ("The Chemical Examination of Technical Products") Edited by DR. GEORG LUNGE. Vol. I. Fifth Edition. Berlin: Julius Springer. 1904.

In the fifth edition of this valuable work many important changes have necessarily been made, some sections being written by new authors; as, for example, those on the analysis of water and air, which come from the pens of Dr. L. W. Winkler and Dr. K. B. Lehmann respectively. Every part of the work has also been carefully revised, and many additions have been made. The general part by Dr. Lunge gives directions for taking samples, and useful hints on the performance of all ordinary analytical operations by the most accurate and expeditious methods. In the special part in each case the examination and analysis of the raw substances, by-products, and final products are successively described, with great attention to detail, by writers who are specialists in the particular branches they treat of; thus the editor writes the sections on the mineral acids, soda, and chlorine; Dr. Ferd. Fischer is responsible for the chapters on technical gas analysis, and Dr. H. Freudenberg for cyanogen compounds. The repetition of the various tables, which appear in the text on separate sheets so that they may be readily detached from the book and used in the laboratory by themselves, will no doubt be found a great convenience.

The second and third volumes, on which no fewer than thirty-eight collaborators are engaged, are to appear shortly.

Die Beziehungen Zwischen Äquivalent-volumen und Atomgewicht. ("The Relations between Equivalent Volume and Atomic Weight"). By Dr. W. BORCHERS. Halle-a-S.: Wilhelm Knapp. 1904.

At the beginning of this pamphlet Dr. Borchers informs his readers that during the preparation of the new edition of his "Elektrometallurgie" in endeavouring to find an explanation of some apparent anomalies in the Periodic Table he arrived at certain important results relating to the electro-chemical equivalents of the elements, which results are here published and discussed. Taking the equivalent volumes (numerically equal to the equivalent weights divided by specific gravity) as ordinates, the atomic weights being the abscissae, Dr. Borchers obtained systems of curves which exhibit a surprising regularity, and the careful examination of these curves has enabled him to predict the discovery of a certain number of new elements, and to correct the atomic weights of others; for instance, according to the curve for the alkali metals, two unknown elements of this group exist of atomic weight 178 and 221 respectively, the one being probably a liquid and the other a gas; also the curves appear to show that either the right atomic weight has not been ascribed to ytterbium, or else this substance is not elementary. These are only specimens of the predictions the author makes in a paper which will well repay careful reading.

Die Elektrochemische Industrie Deutschlands. ("The Electro-chemical Industry of Germany"). By P. FERCHLAND, Dr. Phil. Halle-a-S.: Wilhelm Knapp. 1904.

THE difficulties attending the amassing of the materials, even for such a small book as this, are undoubtedly very considerable, chiefly because manufacturers exhibit a not unnatural tendency to conceal the most important details of the processes they find most profitable, and the author of this monograph has for this reason been unable to give as complete an account of his subject as might be desirable, in spite of the fact that he has carefully studied all available sources of information. The book contains a very brief outlined description of the application of the methods of electro-chemistry to the preparation of alkali and the various metals, and covers such a wide ground that it would be unreasonable to expect in it a great attention to detail. The author is somewhat given to making sweeping statements, the truth of which can hardly be accepted; for example, he is exceedingly sceptical about the use of electro-chemical methods in the preparation of organic products; in fact, he goes so far as to say that organic and electro-chemistry are as unmixable as oil and water, and instances the manufacture of iodoform as practically the only organic electro-chemical industry of Germany, thus quite passing over the preparation of the by-products of the coal-tar colours, naphthylamine, &c., which are now largely produced by electrical methods. Another error has crept into the chapter dealing with electrical bleaching, of which industry Kellner cannot be said to be the founder, for Hermite was undoubtedly the pioneer in this particular branch, and patented his process six or seven years before Kellner.

Die Materialien der Stereochemie. ("The Materials of Stereo-chemistry"). By C. A. BISCHOFF. Two Vols. Braunschweig: Friedrich Vieweg und Sohn. 1904.

THE collection of all data relating to the study of stereochemistry in this form is an excellent idea, and will commend itself to all who have occasion to look up any questions dealing with the subject. The text is arranged in the form of yearly reports extending from 1894 to 1902

inclusive, the preceding period being contained in the "Handbuch der Stereochemie," by C. A. Bischoff and P. Walden, to which these volumes may be regarded as a sort of enlarged supplement, and in each report the subject-matter is conveniently divided under the headings General Stereo-chemistry, Optical Isomerism, Geometrical Isomerism of Optically Inactive Substances, and the Relations between Spatial Arrangement and Chemical Reactions. Under these divisions books relating to each branch of the subject are noticed, and their contents given with a short review of points of special interest treated in them, and important papers which have appeared in various periodicals are very clearly abstracted. It is a pity, however, that preference is given so decidedly to works published in Germany only. The whole work is most admirably indexed, and the contents are so classified as to add greatly to the value and convenience of the book.

Flüssige Kristalle. ("Liquid Crystals"). By Dr. O. LEHMANN. Leipzig: Wilhelm Engelmann. 1904.

The author of this exhaustive treatise has boldly shaken himself free of all the trammels of theories relating to the three distinct states of aggregation, and attacks the questions of the existence of liquid crystals from the point of view of experimental observation alone. In this book, which is undoubtedly the most complete dealing with this subject extant, Dr. Lehmann, with all the vivacity and dexterity at his command, examines into the conceptions underlying the words liquid and crystal in order to justify their joint application to the well-known phenomena of anisotropic liquids, and gives a most complete statement of his case with all opposing arguments well threshed out. He describes very minutely the experimental arrangements adopted for the microscopic investigation of the phenomena in question, and appends to the text some beautifully executed photographs illustrating the various points in the treatise. In the short conclusion the application to biological problems is very briefly stated. Dr. Lehmann is perhaps rather disposed to over-estimate the importance of the discovery of the existence of liquid crystals and of the directive effects of molecular forces, which, in spite of what he says, has received a very fair amount of attention both from investigators and in text-books of physics; however, he has produced a valuable monograph on a very interesting subject.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 4, July 25, 1904.

The Form taken by Thallous Iodide when going into Solution.—D. Gernetz.—The author has already shown that when yellow thallous iodide is heated to 168° it is transformed into the cubic red iodide. The inverse reaction also takes place. He now proves that, at temperatures lower than 168°, if a solution of either form is made in any solvent whatsoever, and then—either by cooling or evaporation of the solvent—crystallisation takes place, the red variety, which is naturally unstable at these temperatures, always separates out.

Radio-active Lead, Radio-tellurium, and Polonium.—A. Debieuvre.—Already inserted in full.

Action of Zinc on Sodium Tungstates.—L. A. Hallopeau.—The author examines the reaction of zinc on neutral sodium tungstate, $\text{Na}_2\text{WO}_3 \cdot 2\text{H}_2\text{O}$, and sodium paratungstate, $5\text{Na}_2\text{O} \cdot 12\text{WO}_3 \cdot 28\text{H}_2\text{O}$. The latter can easily be prepared pure from commercial sodium tungstate. He finds that in the latter case the reaction is totally

different from that when the ammonium salt is used. The zinc first reduces a portion of the tungstic anhydride of the acid sodium tungstate. This first reaction gives the golden-yellow tungsto-sodic tungstate, and, in certain cases, a little tungsten. The oxide of zinc and the neutral sodium tungstate which are thus formed mutually react on each other to form the neutral zinc tungstate.

Acid Silver Pyrophosphate.—J. Cavalier.—The author prepares acid silver pyrophosphate by dissolving neutral silver pyrophosphate in pyrophosphoric acid. The mass when cooled is a thick syrup, which does not crystallise, but gives with alcohol or ether the acid pyrophosphate of silver, $\text{P}_2\text{O}_7\text{Ag}_2\text{H}_2$, in the form of a white powder, crystalline if the deposition is made slowly. The salt becomes pasty at 150°, and is quite liquid at 240°, and at this point begins to slowly decompose, losing water and turning into the metaphosphate, PO_3Ag . It is rapidly decomposed by water in the cold: $2\text{P}_2\text{O}_7\text{Ag}_2\text{H}_2 + \text{H}_2\text{O} = \text{P}_2\text{O}_5\text{Ag}_2 + \text{P}_2\text{O}_5\text{H}_2$.

Composition of the Homologues of Schweinfurt's Green.—Georges Viard.—The author prepares and analyses the formic, propionic, and butyric homologues of Schweinfurt's green. These are obtained by adding to a boiling aqueous solution of arsenious anhydride the solution of the organic salt of copper added to an excess of its acid. On continuing the boiling the substance separates in green crystalline flakes. These are very stable. The formio-arsenite of formula $(\text{CHO})_2\text{Cu} \cdot 3(\text{AsO}_2)_2\text{Cu}$ not decomposing at 170°, whilst the propiono-arsenite, $(\text{C}_3\text{H}_5\text{O}_2)_2\text{Cu} \cdot 3(\text{AsO}_2)_2\text{Cu}$, and the butyro-arsenite, $(\text{C}_4\text{H}_7\text{O}_2)_2\text{Cu} \cdot 3(\text{AsO}_2)_2\text{Cu}$, only decompose at temperatures above 200°.

Heat of Formation of Antimony Trisulphides.—MM. Guinchant and Chretien.—The authors' number for the heat of formation of antimony trisulphide differs from that given by M. Berthelot. They explain this difference by the fact that the red sulphide which intervenes is not identical in the two methods.

Scientific Phenomena accompanying Polishing.—F. Osmond and G. Cartaud.—The authors explain and illustrate a theory of glass cutting by means of a diamond and various phenomena connected with polishing.

Vinyldimethylacetic Acid.—E. E. Blaise and A. Courtot.—Vinyldimethylacetic acid is the same as that to which M. Bouveault gives the name dimethylisocrotonic acid. Its constitution is absolutely proved by its oxidation by means of potassium permanganate. When this oxidation takes place at 0° in dilute solution the yield of dimethylmalonic acid is small, but in a 5 per cent solution (the temperature being higher) a good yield is produced. True vinyldimethylacetic acid when treated with sulphuric acid does not give lactone.

β -Oxalacetyl and β -Oxyphenol Ethylenic Acetones. Action of Hydroxylamine and Hydrazine.—Ch. Moureu and M. Brachin.— β -Oxalacetyl- and β -oxyphenol-ethylenic acetones, when reacting upon hydroxylamine and hydrazine, do not give directly either oximes or hydrazones, as is generally the case, but isoxazols and pyrazols are formed instead.

Action of Oxalacetic Ether on Aromatic Aldehydes in presence of β -Naphthylamine.—L. J. Simon and A. Conduché.—The authors find that, when oxalacetic ether acts on aromatic aldehydes in presence of β -naphthylamine, the principal product of the reaction results from the equimolecular addition of ether and the benzyldienic combination,

$$\text{CO}_2\text{C}_2\text{H}_5 \cdot \text{CO} \cdot \text{CH} \cdot \text{CO}_2\text{C}_2\text{H}_5$$

$$\text{C}_6\text{H}_5 \cdot \text{CH} \cdot \text{NH} \cdot \text{C}_2\text{H}_5$$

Action of Acid Chlorides on Tertiary Bases having an Aromatic Radicle.—V. Auger.—The author finds that, at a temperature of 200° to 250°, all the acid chlorides act on the tertiary bases of the type $\text{Ar} \cdot \text{N} = \text{Al}_1\text{Al}_2$, and give an acyl-derivative in quantitative yield:— $\text{Ar} \cdot \text{N} : \text{Al}_1\text{Al}_2 + \text{ROCl} = \text{Ar} \cdot \text{N} \cdot \text{Al}_1 \cdot \text{COR} + \text{Al}_2\text{Cl}$. Al_1 representing the radicle possessing the lowest molecular weight.

No. 5, August 1, 1904.

Synthesis of certain Alcohols in the Cyclohexane Series.—Paul Sabatier and Alph. Maihe.—By applying M. Grignard's methods to a chloro-magnesium derivative of cyclohexane, the authors are enabled to synthesise other series of alcohols represented by the general formula $C_6H_{11}-COH \leftarrow \begin{smallmatrix} R \\ R' \end{smallmatrix}$; where R and R' can be hydrogen or hydrocarbon residues of various forms.

Action of Ammonia on Boron Bromide and Phosphorus Chloride.—A. Joannis.—When dry ammonia acts on boron bromide at about -10° a decomposition takes place, boron imide and ammonium bromide being formed. If the reaction takes place at 0° , the ammoniacal ammonium bromide is formed according to the equation $2BBr_3 + 27NH_3 = 6(NH_4Br_3NH_3) + B_2(NH_3)_3$. The author then causes ammonia to act on phosphorus chloride by passing the vapour of the latter by means of a stream of hydrogen into liquefied ammonia at -78° . In spite of this low temperature he is not able to obtain the amide $P(NH_2)_3$, but either a mixture of amide and imide, or, more usually, a body of formula $NH=P-NH_2$ is produced. When the reaction is finished, the excess of ammonia is evaporated at -23° , and there remains only the ammonia combined with ammonium chloride and the body above referred to: $PCl_3 + 14NH_3 = 3(NH_4Cl \cdot 3NH_3) + NH=P-NH_2$.

Estimation of Bismuth by Electrolysis.—A. Holland and L. Bertiaux.—The authors describe a method by which a very exact estimation of bismuth may be made, even in the presence of considerable quantities of copper and lead. This consists in obtaining the metals in the state of sulphate not containing a large excess of H_2SO_4 . They are then precipitated, when boiling, by excess of phosphoric acid. The precipitate is left to settle overnight. Next day it is filtered and washed with dilute phosphoric acid and then with ammonium sulphohydrate and potassium cyanide. The precipitate of bismuth phosphate is dissolved in dilute nitric acid and the solution evaporated in presence of sulphuric acid till white fumes appear. The bismuth is now in the state of pyrophosphate; this is diluted and electrolysed with a current of 0.1 ampère, when the bismuth absolutely separates.

Berichte der Deutschen Chemischen Gesellschaft.

Vol. xxxvii., No. 12, 1904.

Oxidation Products of β -Phenylene Diamine.—Ernst Erdmann.—The oxidation of β -phenylene diamine has for some time been known to produce brown and black colours, and this property has found practical application in colouring skins, &c. In this first communication the author describes his investigations of these oxidation products, produced by the action of permanganate. Using a solution of chemically pure β -phenylene diamine, a 1 per cent solution of permanganate is appreciably decolourised in the cold. The molecule of diamine is split up, most of the nitrogen being converted into ammonia; a small part of it (about 1 per cent of the diamine used) goes to form hydrocyanic acid. The formation of this latter product may be the explanation of the toxicological effects of the diamine. Possibly isonitroso-malonic acid is formed as an intermediate product, which readily splits up into carbon dioxide, hydrogen cyanide, and water. Oxalic acid is also formed during the oxidation, but both this and hydrocyanic acid are only secondary products, the principal reaction giving rise to CO_2 and NH_3 , and proceeding according to the reaction $C_6H_8N_2 + 13O = 6CO_2 + 2NH_3 + H_2O$.

Removal of Alkyl Groups from Secondary Amines.—J. von Braun.—The author discovered some time ago that tertiary amines, R_3N , by means of the bromocyanogen reaction could be made to yield dialkyl cyanamides, $R_2N.CN$, which practically amounts to converting tertiary into secondary bases. He has now found a method of further decomposing secondary amines so as to remove the alkyl residue R, so that we can obtain a given nitrogen

atom with any desired number of alkyl residues attached to it. If dialkyl amides which contain a benzene, substituted benzene, or naphthalene residue are converted into amide chlorides, and heated, or if, more simply, PCl_5 is allowed to act on the amide (in molecular proportions) 1 molecule of alkyl chloride is split off on heating for a short time, and on heating for a longer time to a higher temperature the second molecule of alkyl chloride is eliminated. If one of the two alkyl residues attached to the nitrogen is aromatic, the reaction obviously consists of the splitting off of a molecule of fatty alkyl chloride, and the formation of the double aromatic imide chloride (e.g., $C_6H_5.CCl.N.C_6H_5$). Secondary fatty bases can thus be decomposed to form ammonia, and fatty aromatic bases to primary aromatic bases: $R_1CCl_2.NR_2 = R_1CCl.NR + ClR$, $R_1CCl_2.NR_2 = R_1C.N + 2ClR$. Though of only theoretical interest, this reaction is of importance when applied to aromatic acylid derivatives of cyclic bases, for it leads to a new method of splitting up nitrogenous rings, and to a series of substances hitherto only prepared with great difficulty, and applicable for further syntheses.

MISCELLANEOUS.

British Association for the Advancement of Science.—The following are the names of the Officers and Committee of Section B (Chemistry) at the Cambridge Meeting of the British Association:—

President.—Prof. Sydney Young, D.Sc., F.R.S.
Vice-Presidents.—Prof. Sir James Dewar, M.A., LL.D., F.R.S.; Prof. W. N. Hartley, D.Sc., F.R.S.; J. J. Dobbie, D.Sc., F.R.S.

Secretaries.—Prof. W. J. Pope, F.R.S. (Recorder); M. O. Forster, Ph.D., D.Sc.; Prof. G. G. Henderson, M.A., D.Sc.; H. O. Johns, M.A., D.Sc.

Committee.—John Angell; Prof. H. E. Armstrong, F.R.S.; Prof. O. Aschan; William Barlow; G. T. Beilby; Sir I. Lowthian Bell, F.R.S.; J. Carter Bell; Prof. J. Brühl; J. Y. Buchanan, M.A., F.R.S.; Prof. M. Busch; F. D. Chattaway, M.A., D.Sc.; Holland Crompton; Prof. A. W. Crossley, Ph.D., D.Sc.; Prof. C. Dieterici; Prof. H. B. Dixon, F.R.S.; Prof. A. E. Dixon, M.D.; A. Etard, D.Sc.; T. Fairley; H. J. H. Fenton, F.R.S.; Prof. Ferguson, M.A., LL.D.; Prof. A. P. N. Franchimont; Prof. M. Freund; Prof. S. Gabriel; Comte A. de Gramont; Prof. Groth; Prof. P. Guye; Prof. A. Haller; A. Vernon Harcourt, D.C.L., F.R.S.; M. Hayashi, D.Sc.; C. T. Heycock, F.R.S.; J. Hübner; Francis Jones; Prof. E. Knoevenagel; A. Lapworth, D.Sc.; Prof. Leduc; Prof. G. D. Liveing, F.R.S.; Prof. A. Liversidge, F.R.S.; H. McLeod, F.R.S.; H. Marshall, F.R.S.; K. Matsubara, Ph.D.; Prof. R. Meyer; H. Forster Morley, D.Sc.; R. S. Morrell, M.A.; M. M. Pattison Muir, M.A.; F. H. Neville, F.R.S.; E. Noelting; M. Ogawa; Prof. K. J. P. Orton; H. Ramage, M.A.; Sir W. Ramsay, K.C.B., F.R.S.; Prof. J. E. Reynolds, M.D., F.R.S.; Prof. P. van Romburgh; Sir H. E. Roscoe, F.R.S.; S. Ruhemann, Ph.D.; H. Rupe, Ph.D.; A. Scott, F.R.S.; W. J. Sell, F.R.S.; W. A. Shenstone, F.R.S.; Prof. A. Smithells, F.R.S.; J. Smyth; Prof. J. J. Sudborough, D.Sc., Ph.D.; W. Thomson; T. E. Thorpe, C.B., F.R.S.; Prof. I. Traube; Prof. P. Walden; Sir Thomas Wardle, F.G.S.; Prof. E. Wedekind; Prof. R. Wegscheider; Prof. R. Wolfenstein; Dr. A. Harden; Dr. A. Hutchinson.

The papers brought before the Section were as follows:—

Prof. Sir James Dewar—On New Low Temperature Phenomena and their Scientific Applications.

Ozone Considered as an Oxidising Agent.—R. Luther and J. K. H. Inglis.—The authors have observed that after an electrolysis, the liquid near to the anode has a considerable oxidising power; a supplementary platinum electrode plunged into this liquid and connected with a normal calomel electrode forms an element having an electromotive force of about 1.1 volts. This phenomenon cannot be attributed to dissolved oxygen or to peroxide of hydrogen, the value of their oxidation potential not agreeing with the figure thus found. This value of the electromotive force being found as well in the electrolysis of NO_2H or PO_4H_3 as in H_2SO_4 , there can be no question of persulphuric acid or of Caro's acid, as the authors supposed at first. Finally, the phenomenon disappears in alkaline solutions. For all these reasons they have come to the conclusion that its production is due to the oxidising action of the dissolved ozone. Experiments having confirmed this opinion, the authors undertook the systematic examination of the potential of oxidation of ozone dissolved in acid solutions. They have observed that in contact with electrodes of polished platinum, ozone gives rise to an electromotive force which, at a given temperature, depends on its concentration and on that of the H ions, and can be determined to about 1 millivolt. The potential of oxidation of the electrode is lowered if the former is previously charged with oxygen, and it is increased if it is previously charged with hydrogen; we can prevent these causes of error by first plunging the electrode into an acid solution of ferroso-feric salts, which practically frees it from both these gases. The authors give the formulæ by which we can calculate the electromotive force of a platinum-ozone electrode in functions of the concentration of the ozone and of the H ions; also that of an ozone-hydrogen cell, at $+2^\circ$, in functions of the concentration of the ozone. They are led to the conclusion that ozone might be the anhydride of a weak acid, of which the formula would be H_2O_7 or H_2O_8 . They observed finally that the action of ozone in acid solution on iodide of potassium in neutral solution sets free three atoms of iodine per molecule of ozone; in neutral solutions two atoms of iodine only are set free. In the same manner the action of ozone on a ferrous salt, in neutral solution, oxidises two molecules of ferrous salt per molecule of ozone.—*Zeit. Physik. Chem.*, vol. xliii., p. 203.

COUNTY OF LONDON.

To LIME MERCHANTS, MANUFACTURING CHEMISTS, AND OTHERS.

The LONDON COUNTY COUNCIL invite

Tenders for the Supply of—

- 23,800 Tons of LIME, and
- 5,550 Tons of PROTOSULPHATE OF IRON (Commercial Green Vitriol)

to the Barking Outfall Works, near Beckton, North Woolwich, and the Crossness Outfall Works, near Erith, Kent.

Forms of Tender and other particulars may be obtained upon application to the Council's Chief Engineer, Mr. MAURICE FITZMAURICE, C.M.G., at the County Hall, Spring Gardens, S.W.

Each Tender, which must be upon the Official Printed Form and comply with the instructions contained therein or be rejected, is to be delivered at the County Hall, in a sealed cover marked "Tender for Lime" or "Tender for Protosulphate of Iron" and addressed to the Clerk of the London County Council, not later than 10 o'clock a.m. on TUESDAY, the 4th day of OCTOBER next.

The Council does not bind itself to accept the lowest or any Tender, and it will not accept the Tender of any person or firm who shall on any previous occasion have withdrawn a Tender after the opening of the same, unless the reasons for the withdrawal were satisfactory to the Council.

G. L. GOMME,
Clerk of the London County Council.
The County Hall, Spring Gardens, S.W.,
September 2nd, 1904.

THE SIR JOHN CASS TECHNICAL INSTITUTE.

JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.

EVENING CLASSES IN CHEMISTRY, METALLURGY, PHYSICS, and MATHEMATICS.

Designed to meet the requirements of those engaged in CHEMICAL, METALLURGICAL, and ELECTRICAL INDUSTRIES,

and in trades associated therewith.

Also preparation for the B.Sc. Examination of London University.

Every facility for Special and Advanced Practical Work in well-equipped Laboratories, both in the Afternoon and Evening

CHEMISTRY	{ CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.
PHYSICS	{ R. S. WILLOWS, D.Sc., M.A.
METALLURGY	{ C. O. BARNISTER, Assoc. R.S.M.
MATHEMATICS	{ G. M. K. LEGGETT, B.A.

CLASSES IN METALLURGY.

GENERAL METALLURGY.

THE METALLURGY OF GOLD, SILVER, and LEAD.

FUEL and REFRACTORIAL MATERIALS.

METALLOGRAPHY, including PYROMETRIC WORK.

ASSAYING.

ANALYTICAL CHEMISTRY.

Including ELECTROLYTIC and GAS ANALYSIS.

Each Course of Lectures will be accompanied by suitable Laboratory Work.

GLASS BLOWING.

A series of Courses of Instruction will be given during the Session by Mr. A. C. COSSOR.

New SESSION begins MONDAY, SEPT. 26th,

The Institute is readily accessible, and near to Fenchurch Street, Liverpool Street, Broad Street, and Metropolitan Railway Stations.

For details of the Classes apply at the Office of the Institute, or by letter to the PRINCIPAL.

W. H. DAVISON, M.A.,
Clerk to the Governing Body.

THE POLYTECHNIC,

309, REGENT STREET, W.

UNIVERSITY OF LONDON PREPARATION CLASSES.

Full Courses of Instruction for Matriculation, Inter. Arts, Science, and Engineering, and Final Arts. Examinations are held at the above Institute.

NEXT TERM commences SEPTEMBER 16th, 1904.

Courses are so arranged that Students can do the work on Saturday and one evening per week.

Full particulars can be obtained on application to the DIRECTOR OF EDUCATION.

CITY OF LONDON COLLEGE,

WHITE STREET and ROPEMAKER STREET,
MOOKFIELDS, E.C.

MICHAELMAS TERM commences OCTOBER 3rd.

CLASSES and LABORATORY WORK in CHEMISTRY, PHYSICS, BIOLOGY, BOTANY, GEOLOGY, and PHYSIOLOGY. Special preparation for the Examinations of the Pharmaceutical Society, The Conjoint Board. Complete Courses for University Matriculation and Inter. and Final B.Sc., meeting during the Evening and on Saturday.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

REDRUTH SCHOOL OF MINES, CORNWALL.

Session 1904-1905 begins September 7th.

A "Mining Certificate" is awarded to Students passing successfully through the School Course.

PRACTICAL MINING CLASSES, under the Instruction of Capt. WILLIAM HANLEY (late Government Inspector, South Africa). Distinctions in Mine Surveying in Open Examination five years in succession, including five Medals and Prizes, being all the awards of the City and Guilds of London Institute in 1904 in this subject.

SYLLABUS and every information on application to—

THE REGISTRAR.

RADIUM BROM.

POLONIUM.

(STUDENTS' NUMBER).

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF LONDON.

CANDIDATES for any Degree in this University must either have passed the Matriculation Examination in this University, or be admitted under the Statute which provides that the Senate may admit graduates of or persons who have passed the examinations required for a degree in other Universities approved by it. This and all other Examinations of the University, together with the Prizes, Exhibitions, Scholarships, &c., are open to Women upon exactly the same conditions as to Men.

There are three Examinations for Matriculation in each year; one commencing on September 12th, one on the second Monday in January, and the third on the second Monday in June (or July, as may hereafter be determined).

Every candidate entering for the Matriculation Examination must pay a Fee of £2. If a candidate withdraws his name, or fails to present himself at the Examination, or fails to pass it, the Fee shall not be returned to him.

Candidates are not approved by the Examiners unless they have shown a competent knowledge in each of the following five subjects:—(1) English; one paper of three hours. (2) Elementary Mathematics; two papers of three hours each. (3) Latin or Elementary Mechanics, or Elementary Physics—Heat, Light, and Sound, or Elementary Chemistry, or Elementary Botany; one paper of three hours in each subject. (4) and (5) Two of the following subjects, neither of which has already been taken under Section (3); one paper of three hours in each subject; if Latin be not taken, one of the other subjects selected must be another Language from the List, either ancient or modern:—Latin, Greek, French, German, Arabic, Sanskrit, Spanish, Portuguese, Italian, Hebrew, Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced), Elementary Mechanics, Elementary Chemistry, Elementary Physics—Heat, Light, and Sound, Elementary Physics—Electricity and Magnetism, Elementary Biology—Botany, Elementary Biology—Zoology. Candidates in subjects marked with asterisk must give at least two months' notice before the commencement of the Examination.

A Pass Certificate, signed by the Principal, will be delivered to each successful candidate after the Report of the Examiners has been approved by the Senate.

Several valuable Scholarships and Exhibitions are available to students.

INTERMEDIATE EXAMINATION IN SCIENCE.

The Intermediate Examination in Science will commence on the second Monday in July.

No candidate (with the exception of such as have obtained Honours at the Matriculation Examination in the preceding January) is admitted to this Examination within one academical year of the time of his passing the Matriculation Examination.

The Fee for this Examination is £5.

Examination for Honours.

Candidates for Honours in Chemistry will be examined in Inorganic Chemistry, treated more fully than in the Pass Examination. This Examination will consist of two printed papers and a practical examination.

In the Examination for Honours, the Candidate, not being more than 22 years of age at the commencement of the Pass Examination, who most distinguishes himself will receive an Exhibition of £40 per annum for the next two years.

B.Sc. EXAMINATION.

The B.Sc. Examination will be held on the fourth Monday in October.

Candidates for this Examination are required to have passed the Intermediate Examination in Science at least one academical year previously, and to have passed the Matriculation Examination at least three years previously.

The Fee for this Examination is £5.

Examination for Honours.

For the examination for Honours in Chemistry candidates are required to show a general acquaintance with General Theoretical Chemistry, Chemistry of Carbon Compounds, Physical Chemistry, and History of Chemistry since the time of Boyle.

The candidate, being not more than 23 years of age, who most distinguishes himself in Chemistry, will receive £50 per annum for the next two years, with the style of University Scholar.

DOCTOR OF SCIENCE.

The examination for the Degree of Doctor of Science takes place annually within the first twenty-one days of June.

No candidate is admitted to the examination for the Degree of D.Sc. until after the expiration of two Academical Years from the time of his obtaining the Degree of B.Sc. in this University.

Every candidate for this Degree must state in writing the special subject within the purview of the Faculty of Science, as set out in the Programme of the B.Sc. Examination, upon a knowledge of which he rests his qualification for the Doctorate; and with the Form of Entry he shall transmit an original Dissertation or Thesis (at least six copies), printed, type-written, or published in his own name, treating scientifically some special portion of the subject so stated, embodying the result of independent research, or showing evidence of his own work, whether conducted independently or under advice, and whether based on the discovery of new facts observed by himself, or of new relations of facts observed by others, or, generally, tending to the advancement of Science. Every candidate may further specify any printed contribution or contributions to the advancement of Science which he has at any time previously published. If the Dissertation or Thesis be approved by the Examiners, the candidate shall be required to present himself at the University upon such day or days as may be notified to him, and shall, at the discretion of the Examiners, be further tested, either orally or practically, or by printed questions or by all of these methods, with reference both to the special subject selected by him and to the Thesis.

PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.

This Examination takes place twice in each year, once, for Pass and Honours, commencing on the second Monday in July; and once for Pass Candidates only, commencing on the third Monday in January.

The Fee for this examination is Five Pounds.

UNIVERSITY OF OXFORD.

Waynflete Professor of Chemistry—W. Odling, F.R.S.
Lees Reader in Chemistry—G. Brereton Baker, M.A.

Every Student must reside in one or other of the Colleges or Halls, or in licensed lodgings, for a period of three years. Students of Chemistry can obtain the degree of B.A. by passing preliminary examinations in Arts and in Science, and a final Honour examination in Chemistry. Chemistry may also be taken as part of the examination for a Pass degree. Graduates of other Universities suitably qualified can obtain the degree of Bachelor of Science after an approved course of study or research and two years' residence.

University Laboratory.—Demonstrators, W. W. Fisher, M.A., J. Watts, M.A., and J. E. Marsh, M.A.—The fee for students working in the Laboratory for three days in the week during the Term is £3; for students working every day, £5.

Scholarships of about the value of £80 are obtainable

at the majority of the colleges, by competitive examination in Natural Science.

More detailed information may be obtained from the Examination Statutes; the Student's Handbook to the University; and from the professors and college tutors.

UNIVERSITY OF CAMBRIDGE.

Professor of Chemistry—G. D. Liveing, M.A., F.R.S.
Jacksonian Professor of Natural and Experimental Philosophy—Sir James Dewar, M.A., F.R.S.

The Student must enter at one of the Colleges or Hostels, or as a Non-collegiate Student, and keep terms for three years by residence in the University. He must pass the previous examination in Classics and Mathematics, which may be done in any term of residence or before commencing residence. He may then proceed to take a Degree in Arts, either continuing mathematical and classical study, and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes.

A graduate of another University may be admitted as an "advanced" student, and obtain a degree after two years' residence in the University.

The scholarships, ranging in value from £20 to £100 a year, are chiefly given for mathematical and classical proficiency. Scholarships, or Exhibitions, are given for Natural Science in King's, Trinity, St. John's, St. Peter's, Clare, Trinity Hall, Queen's, Jesus, Christ's, Emmanuel, Sidney, Pembroke, Caius, and Downing Colleges; the dates of the examinations vary, but are always fully advertised.

The Chemical Laboratory of the University is open daily for the use of the Students. The Demonstrators attend daily to give instructions. A list of the lectures is published annually, in June, in a special number of the *Cambridge University Reporter*, which may be had from the Cambridge Warehouse, in Paternoster Row, or through any bookseller.

Non-collegiate Students are allowed to attend certain of the College Lectures and all the Professors' Lectures, and have the same University status and privileges as the other Students. Full particulars may be obtained by forwarding a stamped directed envelope to the Assistant Registrar, Cambridge, or from the *Cambridge University Calendar*.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

Professor of Chemistry—Sydney Young, D.Sc., F.R.S.
Assistant Lecturer—Emil A. Werner, F.C.S., F.I.C.
Demonstrator—W. C. Ramsden, F.C.S.

The general Quantitative and Research Laboratories include working accommodation for about 130 Students. The Laboratories will open on the 2nd of October. Lectures will commence about November 1st.

The Laboratories and the Lectures of the Professor of Chemistry can now be attended by Students who do not desire to reside in the University or proceed to its Degrees.

The full Course of General and Analytical Chemistry occupies three years, but a Student is free in his third year to devote most of his time to a special department of Pure or Technical Chemistry. Students can enter for any portion of the Course. The Lectures delivered are:—

1. *Inorganic Chemistry and Chemical Philosophy*.—Elementary, first year; Advanced, including Physical Chemistry, second year.
2. *Organic Chemistry*.—General, second year; advanced, third year.
3. *Metallurgy*.—A Course for Engineering and Technical Students.

The Laboratories are open every day from 10 to 5 o'clock (except Saturdays, when they close at 1 o'clock).

The *Summer Course of Practical Chemistry for Medical Students* begins during the first week in April and terminates with the first week in July.

The University of Dublin grants the Degree of Doctor of Science to graduates of Master's standing whose independent researches in any branch of Science are of sufficient merit.

By recent decrees, Prizes in Chemistry and Physics will be given in future at the October (Arts) Entrance Examination, and also at the Terminal Examinations of the Junior and Senior Freshmen Years.

Similarly, two Science Scholarships will be obtainable by Freshmen, and tenable for five years. These Foundation Scholars receive £20 per annum, have free commons, their chambers for half the charge paid by other students, and their tutorial fees are at one-fourth the usual rates.

KING'S COLLEGE.

(DIVISION OF ENGINEERING, ARCHITECTURE, AND APPLIED SCIENCE).

Professor of Chemistry—J. M. Thomson, F.R.S., F.C.S.
Lecturer—Herbert Jackson, F.C.S.

Demonstrators—P. H. Kirkaldy, F.C.S., Dr. Northall Laurie, F.C.S., and Sir W. Collins.

The Academical Year consists of Three terms. The days fixed for the Admission of New Students in the Academical Year 1904-1905 are Oct. 5, Jan. 9, and May 1.

Students of the First Year are admitted to the Course of Theoretical and Applied Chemistry. The Course commences with a view of the conditions suitable for the production of Chemical Phenomena, after which the laws of Chemical Attraction are discussed, and the Non-metallic Elements and their principal compounds are described. The Metals and their principal compounds are next examined, care being taken to point out the applications of the Science to the Arts; and the processes of the different Manufactures and of Domestic Economy are explained and illustrated. Examinations of the Class, both *visà voce* and by written papers, are held at intervals during the course at the usual Lecture hour.

Second Year.—Students attend in the Laboratory twice a week, and they go through a course of Chemical Analysis, both by liquid tests and the blowpipe, analysis of ores, liquids, &c., and Elementary Volumetric Analysis.

Experimental and Analytical Chemistry in the Laboratory.—The object of this Class is to afford to Students who are desirous of acquiring a knowledge of analysis, or of prosecuting original research, an opportunity of doing so under the superintendence of the Professor and Demonstrator; Students may enter, upon payment of extra fees, at any time except during the vacation, and for a period of one, three, six, or nine months, as may best suit their convenience. The laboratory hours are from ten till four daily, except Saturday.

In addition to the Laboratory Fee, each Student defrays the expenses of his own experiments. The amount of this expense, which is comparatively trifling, is entirely under his own control.

Special hours and fees are arranged for the convenience of such Third Year Students as wish to study Analytical Chemistry.

Fees.—Chemistry per term, £3 3s.; per ann., £8 8s.; Practical Chemistry per term, £4 4s.; per ann., £10 10s.; Experimental and Analytical Chemistry—Five days a week: One month, £4 4s.; Three months, £10 10s.; Six months, £18 18s.; Nine months, £26 5s. Three days a week: One month, £2 12s. 6d.; Three mos., £6 6s.; Six mos., £11 11s.; Nine mos., £15 15s.

METALLURGY.

Professor—A. K. Huntington, F.I.C., F.C.S., &c.

The following subjects are treated of in the Lectures: The Selection and Economic Preparation of Fuel and of Refractory Materials; the methods by which metals are obtained from their ores, and the means by which they are rendered suitable for the various requirements of the Arts.

Particular attention is paid to the study of the Nature and Properties of Metals and Alloys available for Constructive Purposes.

In the Metallurgical Laboratory, which is always open during College hours, the relation between the Chemical Composition of Metals and their Mechanical Properties may be studied by the aid of Testing Machinery.

Fee, £3 3s. for the Course.

PHOTOGRAPHY.

Lecturer—Prof. J. M. Thomson, F.R.S., F.C.S.
In addition to the regular College Course in Photography occasional classes may be formed. For further particulars application should be made to Prof. Thomson.

EVENING CLASSES.

Classes for Evening Instruction in various subjects are held during the Winter Session.

UNIVERSITY COLLEGE.

FACULTY OF SCIENCE.

Professors—Sir William Ramsay, LL.D., F.R.S., &c. (Inorganic and Physical Chemistry); J. Norman Collie, Ph.D., F.R.S. (Organic Chemistry).

Assistants—E. C. C. Baly, F.I.C.; J. K. H. Inglis, B.Sc., M.A.; N. T. M. Wilmore, M.Sc.; and S. Smiles, D.Sc. The Session is divided into three Terms, as follows:—First Term, from October 4 to December 22; Second Term, from January 10 to March 31; Third Term, from May 2 to June 19. Class Examinations begin June 19.

Introductory Course of Inorganic Chemistry.

Tuesday and Thursday, at 9. Practical, Friday, 2 to 2.30, or 3.30 to 5. Fee, £10 10s.

This Course treats of the chief physical and chemical characters of the Non-metallic Elements, their preparation and characteristic tests.

Junior Course of Inorganic Chemistry.

First and Second Terms: The Class meets four times a week, on Mondays, Wednesdays, Fridays, and Saturdays, at 9, for Lectures, Examinations, and Exercises.

Fees:—For the Course, £7 7s.; for the First or Second Terms, £4 4s.

In this Course the physical principles bearing on Chemistry are first discussed, and the Chemistry of the Elements and their compounds are treated in considerable detail, under the headings—Elements; halides, oxides, sulphides, &c., borides, carbides, and silicides, nitrides, phosphides, &c., and alloys. Special attention is devoted to substances of commercial importance. The concluding Lectures are devoted to Physical Methods and their bearing on Chemical Problems.

Third Term: Lectures will be given on Mondays and Fridays at 9 and on Wednesdays at 11, on the chief types of Carbon Compounds.

An Exercise Class will meet once a week throughout the Session.

Senior Course of Chemistry.

Second and Third Terms.—The class meets twice a week, on Tuesdays and Thursdays, at 9, beginning in January.

Fee:—For the Course, £3 3s.; for a Term, £2 2s.

The Principles of Chemistry will be specially considered, comprising the Atomic Theory, Chemical Classification, the Periodic Law, Thermal Chemistry, Dissociation, the Application of Physical Methods to the Solution of Chemical Problems, and the influence of Mass and Temperature on the progress of Reactions. Special attention is paid to the most recent Chemical Theory researches.

Third Term: Some Lectures will also be given on Saturdays at 9, during the Third Term, on the History of Chemistry.

Organic Chemistry.

Mondays, Wednesdays, and Fridays, at 9, during the session.

This Course is suitable for Students who intend to study Chemistry from a scientific standpoint. No previous knowledge of Organic Chemistry is expected of those attending the Class, which should, however, be taken concurrently with the preceding Course, and with Practical Organic Chemistry in the Laboratory.

Fee:—For the Course, £6 6s.; for a Term, £2 12s. 6d.; for a Second Course, £3 3s.

An Advanced Course will be held twice a week during the First, Second, and third Terms, for those engaged in prosecuting research in Organic Chemistry. Fee, £5 5s.

Practical Classes.

Practical Classes in Inorganic and Organic Chemistry are conducted by the Assistants.

Analytical and Practical Chemistry.

The Laboratory is open daily from 9 a.m. to 4 p.m., Saturdays excepted, from October until the middle of July, with a short recess at Christmas and at Easter.

Fees: for the Session, £26 5s.; six months, £18 18s.; three months, £10 10s.; one month, £4 4s.

Three specified days a week:—for the Session, £15 15s.; six months, £11 11s.; three months, £6 6s.; one month, £2 12s. 6d., exclusive of expense of materials. Students may enter at any period of the Session.

When accompanied by, or preceded by, attendance on the Lectures on Inorganic and Organic Chemistry, the Laboratory Courses qualify Students in the application of Chemistry to Manufactures, Metallurgy, Medicine, or Agriculture, &c.

There is also a Chemical Library containing the chief Journals and Standard Works on Chemistry.

Certificates of Honour are granted to competent Students on the work done during the Session. Several valuable Scholarships are available to students.

ROYAL COLLEGE OF SCIENCE AND
ROYAL SCHOOL OF MINES.

Professor of Chemistry—W. A. Tilden, D.Sc., F.R.S.

Assistant Professor—M. O. Forster, Ph.D., D.Sc.

Demonstrators—H. Chapman Jones; G. T. Morgan, D.Sc., A.R.C.S.; and J. C. Philip, M.A., Ph.D., B.Sc.

Assistants—G. S. Newth and H. Burrows, Ph.D.

The Royal College of Science at South Kensington is intended, primarily, for the instruction of teachers, and of students of the industrial classes selected by competition in the examinations of the Board of Education. The Royal School of Mines is incorporated with the Royal College of Science. Students entering for the Associateship of the Royal School of Mines obtain their general scientific training in the Royal College of Science. The instruction in the Royal College of Science is arranged in such a manner as to give the Students a thorough training in the general principles of Science, followed by advanced instruction in one or more special branches of Science. The Associateship is granted in certain divisions or lines of study. Students who go through any one of the prescribed courses of instruction and pass the necessary Examinations receive a Certificate of Associateship of the Royal College of Science, or of the Royal School of Mines. Students who are not candidates for the Associateship are permitted to enter as occasional students in one or more special branches of science. The Associateship of the Royal College of Science is given in one or more of the following divisions:—Mechanics, Physics, Chemistry, Biology, and Geology, and the Associateship of the Royal School of Mines in Metallurgy and Mining.

The course of instruction lasts for three years, is the same for all the divisions during the first year, after which it is specialised according to the particular division in which the student is working for the Associateship.

Examinations are held at the end of each course of instruction and at such other periods as may be found necessary. On the results of these examinations the successful candidates are arranged in two classes, first and second. There are also "Honours" examinations for the subjects of the third year, the successful candidates being placed in order of merit. A student obtains the Associateship who passes in all the subjects of the first year, and, in the second and third year, those subjects prescribed as necessary for the division in which he seeks to obtain his Associateship. A student who goes through the prescribed course of instruction in any subject except Mining and Metallurgy and passes the necessary examinations receives a certificate to that effect.

Students who do not wish to attend the lectures are admitted for short periods to the laboratories, at the dis-

cretion of the Professors. The fees for the laboratories are £4 per month.

Students not entering for the Associateship are admitted to any particular course of study, so far as there is room, on payment of the fees shown in the following table:—

	Lectures.	Laboratory.
Chemistry	3	13
Physics	5	12
Biology with Botany	5	12
Geology with Mineralogy .. .	4	8
Mechanics	4	6
Metallurgy	2	13
Mining	4	

The fee for the course of Mine Surveying is £10.

The fees for the first two years amount to about £75, and for the remainder of the course for the Associateship they vary from £30 to £40.

The Session is divided into two Terms. The first Term begins about the first week of October, and ends about the middle of February. The second Term begins in the middle of February, and ends about the middle of June.

The hours of study are from 10 a.m. to 1.15, and from 2 to 4 or 5 p.m. every day, except on Wednesday and Saturday, when the College closes at 1 p.m.

Several valuable Exhibitions, Scholarships, and Prizes are attached to the studentship.

Summer Courses for Teachers.—Short courses of instruction are given annually, about July, in different branches of science for the benefit of teachers of science schools in the country. The courses last three weeks. About 250 teachers are admitted to them, and they receive third class railway fare to and from South Kensington, and a sum not exceeding £3 towards their expenses.

THE SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

The Sixty-third Session will commence on Oct. 3, 1904.

Professors—Chemistry, Arthur W. Crossley, D.Sc., Ph.D., F.I.C.; Botany, J. Reynolds Green, Sc.D., F.R.S., F.L.S.; Pharmacaceutics, Henry G. Greenish, F.I.C., F.L.S., (Dean).

A course of Lectures on Physical, Inorganic, and Elementary Organic Chemistry commences in October and terminates at the end of June. An Advanced Course of Lectures begins in October and extends to the end of March. These Lectures are adapted to the requirements of Pharmaceutical and Medical Students, and also of those who are proceeding to degrees at the University of London, or who are preparing for the examinations of the Institute of Chemistry.

Entries may be made for single classes. Certificates of attendance at the two Courses of Lectures on Chemistry and at the Chemical Laboratories are accepted as evidence of chemical training by the Institute of Chemistry in connection with the Examinations for the Associateship, and also by the conjoint Board of the Royal Colleges of Physicians and Surgeons, as well as by other examining bodies.

Prospectuses and further information may be obtained from Mr. Richard Bremridge, Secretary and Registrar, 17, Bloomsbury Square, London, W.C.

UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH.

UNIVERSITY OF WALES.

Professor—J. J. Sudborough, D.Sc. (Lond.), Ph.D. (Heidelberg), F.I.C.

Demonstrators—H. Hibbert, M.Sc. (Vic.), F.I.C., and A. Brooke, Ph.D. (Strassburg).

Lecturer in Agricultural Chemistry—J. Alan Murray, B.Sc. (Edin.).

Lecturer on Dyeing—(Vacant).

The College is open to male and female students above the age of sixteen years. The Session commences on Oct. 4th, on which day all Students will be expected to meet the Professors in the Examination Hall of the College.

Lecture Courses.—(1) Matriculation Course; two lectures weekly throughout the Session. (2) Intermediate Science Course; four lectures weekly throughout the Session. (3 and 4) B.Sc. Courses; A, three lectures weekly on Organic Chemistry; B, three lectures weekly on General and Physical Chemistry. (Courses A and B will generally be given in alternate Sessions; for 1904-1905, Course B). (5 and 6) Courses in Agricultural Chemistry. For students in their first year, 3 lectures, and for those in their 2nd year, 2 lectures weekly during the Michaelmas and Lent terms.

Laboratory Courses.—The Laboratories are open daily from 10 a.m. to 1 p.m., and from 2 to 5 p.m., except on Saturdays. Regular Courses of practical work, suitable for the B.Sc. degree of the Universities of London and Wales, or for the Associateship of the Institute of Chemistry, can be followed. Facilities are given for Students wishing to undertake research work. Special Courses will be arranged for those who intend to follow Medicine or Pharmacy, or any one particular branch of Applied Chemistry, always provided that such Students possess the requisite knowledge of Theoretical Chemistry. The hours will be arranged, as far as possible, to suit the requirements of the individual Student.

The College is recognised by the University of Edinburgh and the Royal University of Ireland, and by the Colleges of Physicians and Surgeons of England, Scotland, and Ireland as an institution at which the instruction necessary for their respective Diplomas in Medicine, in Chemistry, Physics, and Biology may be given. One year for graduation in Medicine and two years for graduation in Science may be spent at Aberystwyth.

Fees.—The Fee for the whole Session, if paid in advance, is £10; if paid by Single Terms, for the first term of attendance in each Session, £4; for the second term, £3 10s.; for the third term, £3. These composition fees enable the Student to attend any or all the Classes of the College, with the exception that a small extra fee is charged for Laboratory Instruction. Thus, for Practical Chemistry, the additional fee is, for six hours' work per week, 12s. 6d. per term, and for twelve hours, 25s. per term. The fees for those who desire to spend several days weekly in the laboratory may be learned on application to the Registrar. Fee for a single Lecture Course £1 per term.

Scholarships and Exhibitions varying in value from £10 to £40 per annum will be offered for competition at examinations which commence on September 15, and exhibitions are awarded at the end of the Session on the results of the class examinations.

Intending Students requiring further information are recommended to write to the Registrar for a copy either of the General Prospectus or of one of the Special Prospectuses issued for the Agricultural and Normal Departments.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

A CONSTITUENT COLLEGE OF THE UNIVERSITY OF WALES. *Chemistry.*—Professor, K. J. P. Orton, M.A., Ph.D., F.I.C. Assistant Lecturer and Demonstrator, Alexander Lauder, B.Sc., F.C.S. Assistant Lecturer in Agricultural Chemistry, Alan Baguley, B.Sc., F.I.C. Junior Demonstrator, Edward Jones, B.Sc.

Physics.—Professor, E. Taylor Jones, D.Sc.

The Session opens October 4th, 1904. All regular classes are open to men and women students above the age of 16 years. The following Courses of Lectures will be given.

Matriculation Course.—Subjects: Those prescribed for the Matriculation Examination of the University of Wales. Fee for the Session £3 3s.

Intermediate Course.—Inorganic Chemistry and Elementary Physical Chemistry. Fee for the Session, £3 13s. 6d.

B.Sc. Course.—Organic Chemistry. Fee for the Session, £3 3s.

Agricultural Chemistry.—Fee, £2 2s.

Laboratory Courses.—The laboratory is open on five days of the week from 10 a.m. to 4 p.m. for instruction in Chemical Analysis and in the Application of Chemistry to Medicine and the Industrial Arts. Fees: six hours per week, £1 1s. per Term; twelve hours, £2 2s.; eighteen hours, £3 3s.; twenty-four hours, £4 4s. Composition Fee for all Laboratory Classes of the Intermediate Science Course taken in one year, £4 4s.

The Chemistry, Botany, Zoology, and Physics Courses are recognised for Medical graduation in the Universities of Edinburgh and Glasgow, and students can make one *Annus medicus* at the college. Students are prepared for the First Examination of the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The Science Courses are recognised for part of the science degree course of the University of Edinburgh.

**UNIVERSITY COLLEGE OF SOUTH WALES
AND MONMOUTHSHIRE, CARDIFF.**

Professor—C. M. Thompson, M.A., D.Sc., F.C.S.

Assistant Professor—E. P. Perman, D.Sc., F.C.S.

Demonstrator—R. D. Anell, D.Sc.

The Session commences October 14th, and terminates on June 23rd, and is divided into three terms.

The Junior Course (delivered during the Michaelmas term only) consists of about 50 lectures, and will cover the subjects prescribed for the Matriculation examinations of the University of Wales and the University of London. Fee, £2 2s. A revision class is held in the Summer term.

The Intermediate Course consists of about 80 lectures held during the Lent and Summer terms in continuation of the Junior Course; together with laboratory practice it forms the qualifying course for the Intermediate Examination of the University of Wales, and will cover the subjects required for the Intermediate Examination in Science of the University of London. Fee, £4 4s.

The Senior Course consists of about 80 lectures on Organic Chemistry; Fee, £3 3s.

A course of 20 lectures on Qualitative Analysis and a short course on Organic Chemistry will also be given.

The following lectures on Metallurgy will be given by Mr. Read:—10 lectures on Fuel; Fee, 10s. 6d. 20 lectures on General Metallurgy; Fee, £1 1s. 30 lectures on the Manufacture of Iron and Steel; Fee, £1 1s. A practical course on Iron and Steel Analysis will also be held, and practical instruction in Dry Assaying will be given in the Metallurgical Laboratory, which is fitted with the necessary furnaces and apparatus.

In the laboratory each student works independently, so that the course of study may be adapted to the requirements of the individual. Hours, 9 to 1 and 2 to 5; Saturday, 9 to 1. Fees—Six hours per week, £2 2s. per term; twelve hours, £3 3s. per term; eighteen or more hours, £4 4s. per term.

Registered medical students can prepare for the Intermediate M.B. Examination of the University of London, and spend three out of their five years of medical study in Cardiff. Medical students wishing to graduate at a Scottish University, or preparing for a Conjoint Board Surgical and Medical Diploma, or for the Diploma of the Society of Apothecaries, can spend two years in Cardiff. For further information see the prospectus of the Faculty of Medicine, which may be obtained from the Registrar.

The College is recognised as an institution at which two years of the course for the degree of Bachelor of Science of the University of Edinburgh may be spent.

Students by making a payment of £10 at the commencement of each session may compound for all lecture fees for the whole session. Laboratory fees are not included in the composition fee, but Students preparing for the Science Examinations of the University of Wales and of the University of London may, by making a payment of £13 13s. at the commencement of each Session, compound for both Lecture and Laboratory Fees during the Session.

At the entrance examination in September, and the annual examination in June, several scholarships and exhibitions are awarded. Great importance is attached to special excellence in one subject.

The College Prospectus, and also further information as to scholarships, may be obtained from the Registrar.

A Hall of Residence for Women Students is attached to the College.

UNIVERSITY COLLEGE, BRISTOL.

Professor of Chemistry—Morris W. Travers, D.Sc., F.R.S.

Assistant Professor—Francis E. Francis, D.Sc., Ph.D.

Lecturer—Oliver C. M. Davis, B.Sc., A.I.C.

Lecture Assistant—J. H. Sturges

The session 1904-1905 will begin on October 4. Lectures and classes are held every day and evening throughout the Session. In the Chemical Department lectures and classes are given in all branches of theoretical chemistry, and instruction in practical chemistry is given daily in the chemical laboratory. The department of experimental physics includes various courses of lectures arranged progressively, and practical instruction is given in the physical and electrical laboratories. The Department of Engineering and the Constructive Professions is designed to afford a thorough scientific education to students intending to become engineers, or to enter any of the allied professions, and to supplement the ordinary professional training by systematic technical teaching. This department includes courses specially arranged for students intending to become civil, mechanical, electrical, or mining engineers, surveyors, or architects. Those who attend the mechanical engineering course enter engineering works during the six summer months, and, in accordance with this scheme, various manufacturing engineers in the neighbourhood have consented to receive students of the College into their offices and workshops as articled pupils at reduced terms. Medical education is provided by the Faculty of Medicine of the College. Several Scholarships are tenable at the College. Full information may be obtained from the Registrar.

DAY LECTURES.

Inorganic Chemistry.

The Courses treat of the principles of Chemistry, and of the Chemistry of the Non-Metals and Metals.

Elementary Course.—Three Lectures a week will be given during the Session. Fee, £3 13s. 6d.

Special Course.—A special course of Lectures is also given to Elementary Teachers.

General Course.—Three Lectures a week will be given throughout the Session. Fee, £3 13s. 6d.

Advanced Course.—Two Lectures a week will be given throughout the Session. Fee, £3 13s. 6d.

Organic Chemistry.

General Course.—Three Lectures a week will be given throughout the Session. Fee, £3 13s. 6d. An advanced course of lectures will also be given one day a week during the session. Fee, £2 2s.

Practical Chemistry.—Laboratory Instruction.

The Chemical and Metallurgical Laboratories will be open daily from 10 a.m. to 5 p.m., except on Saturdays, when it will be closed. Instruction will be given in the Laboratory in all branches of Practical Chemistry, including Qualitative and Quantitative Inorganic and Organic Analysis, the preparation of Chemical Products, Metallurgy, and Inorganic and Organic Research. Special facilities will be afforded to those who desire to study Practical Chemistry as applied to the different processes employed in the Arts and Manufactures. Fees in Guineas—

	5 Days a Week.	4 Days a Week.	3 Days a Week.	2 Days a Week.	1 Day a Week.
Per Session ..	15	12½	10	7½	5
„ Two Terms ..	11	9	7½	5½	3½
„ One Term ..	7	6	4½	3½	2½

Students may arrange to divide their days of laboratory work into half-days.

Chemical Scholarship.—Among others, a Chemical and a Metallurgical Scholarship each of £25 are offered for competition.

EVENING LECTURES.

A course of Lectures, which is subject to variation to suit the requirements of Students, will be delivered during the First and Second Terms. Fee 7s. 6d.

Pharmaceutics.—During the first and second Terms a course of Lectures will be given one evening a week dealing chiefly with the *Materia Medica*, Pharmacy, and Chemistry of the British Pharmacopoeia. Fee, £1 1s.

Practical Chemistry—Laboratory Instruction.—The Laboratory will be open one evening a week from 6 till 9. Instruction will be given in Qualitative and Quantitative Analysis, and in the Preparation of Chemical Products. Fees:—Two Terms, 21s.; One Term, 12s. 6d.

University College, Bristol, has been approved by the Council of the Institute of Chemistry as a College at which all the subjects required for the admission of Associates to the Institute are taught.

The Calendar of the College, price 1s. (post-free, 1s. 4d.), containing detailed information of the various Courses, may be obtained on application to the Registrar.

MERCHANT VENTURERS' TECHNICAL COLLEGE, BRISTOL.

CHEMISTRY AND METALLURGY.

Professor—J. Wertheimer, B.Sc., B.A., F.I.C., F.C.S.

Lecturers—G. P. Darnell Smith, B.Sc., F.I.C., F.C.S.; H. A. M. Borland, A.R.C.S.; I. Williams, B.Sc.

Demonstrators—E. H. T. Parker; P. W. Alloway; C. D. Fuller.

Assistants in Chemical Laboratory—E. H. Fray, H. M. Spencer.

The Laboratories of this Department are open during the Term on every week-day as a School of Practical Chemistry, Analysis, and Assaying, to Students of either sex. They include the Junior Laboratory (for forty Students working at one time), Senior Laboratory, Gas Analysis Room, Balance Room, Combustion Room, Store Rooms, Metallurgical Laboratory, and Research Laboratory. Each Student works independently, and receives individual instruction and help.

The training in this Department is intended to fit Students to become Professional Chemists, to prepare them for Medical or Pharmaceutical examinations in Chemistry, to instruct them in the branches of Applied Chemistry required in Manufactures and Agriculture, and to train them in practical Metallurgical processes, especially Assaying.

Special facilities will be given to Students wishing to undertake research work approved by the Principal; and the Courses provide completely for the Preliminary Scientific Examination (M.B.), and for the Examinations in Chemistry for the B.Sc. degree of the University of London.

The three years' course at this College in the subjects of Theoretical and Practical Chemistry, Theoretical and Practical Physics, and Elementary Mathematics, is accepted by the Council of the Institute of Chemistry as satisfactory evidence of the training of candidates for the Associateship of the Institute, provided the details in each case be certified by the Professors.

Certificates of Proficiency in Assaying will be given to Students who complete a Course of not less than two years' work in the Metallurgical Department, and pass satisfactorily the College examinations in the Theory and Practice of Assaying.

The Laboratories are open every week-day from 9 till 12 noon, and from 1.30 to 4.30 p.m., except Saturday, when they close at noon.

The Annual Fee of £10 to 15s. secures (in addition to the use of either or both Laboratories) permission to attend the Lectures in Physics and Mathematics as well as Chemistry, and to use the Physical Laboratory and the Engineering Workshop.

The College Evening Classes, available to persons of either sex, will commence on Monday, September 26th.

Further detailed information may be obtained from the College Prospectus, price 6d.

UNIVERSITY OF BIRMINGHAM.

Professor—Percy F. Frankland, Ph.D., M.Sc., LL.D., F.R.S.

Assistant Lecturers and Demonstrators—Alex. McKenzie, M.A., D.Sc., Ph.D.; Alex. Findlay, M.A., D.Sc., Ph.D.; T. S. Moore, B.A.

The Session will be opened on October 3rd, 1904.

Lecture Courses.

First Year.—A. This part of the course is arranged (1) to give a full exposition of the general principles of Chemical Science, (2) for the systematic study of the properties of the more important elements and their compounds, and (3) to indicate the chief applications of Chemistry in the Arts and Manufactures. Four hours weekly during the Winter and Spring terms. Mondays to Thursdays inclusive, at 9.30 to 10.30 a.m. Fee, £5 5s. B. This part of the course includes an introduction to the study of Organic Chemistry, with a description of the properties, relations, and methods of preparation of the more important groups of Carbon Compounds. Three hours weekly during the Summer term. Mondays, Wednesdays, and Fridays, at 9.30 to 10.30 a.m. Fee, £1 11s. 6d.

Second Year.—**Advanced Organic Chemistry.**—This course extends over two years, and is divided into two parts:—(a) Carbon Compounds of the Fatty Series; (b) Aromatic and other Cyclic Compounds. Only one of these parts will be taken in each year. The class meets twice weekly by arrangement during the Winter and Spring terms. Fee, £2 2s. **General and Physical Chemistry.**—This course will deal in outline with the more recent developments of Theoretical Chemistry. The class meets once weekly by arrangement during the three terms. Fee, £1 11s. 6d.

Third Year.—A further Course in Advanced Organic Chemistry will deal with one of the above parts of the Course. The class meets two hours weekly by arrangement during the Winter and Spring terms. Fee, £2 2s. A further Course on General and Physical Chemistry, in which special subjects attracting attention at the time receive treatment. Fee, £1 11s. 6d.

Practical Chemistry.

The instruction in Practical Chemistry extends over three years. The Laboratory will be open daily from 9.30 to 5, except Saturdays, when it closes at 1 p.m. Fees—

	All day.	Three hours per day.	Three hours per day; five days a week.	Three hours per day; three days a week.
	Guineas.	Guineas.	Guineas.	Guineas.
One Term ..	7	4½	4	2½
Two Terms ..	13	8½	7½	5
Three Terms ..	18	12	11	6½

A Course of short demonstrations and exercises is given by the Professor or one of his Assistants once a week. All first-year Students are required to attend, unless exempted for special reasons by the Professor. No Fee.

Special facilities are given to Advanced Students for the prosecution of original research.

Metallurgy.

There is a separate University department for Metallurgical students in which provision is made for instruction in assaying, &c.

Scholarships.

Priestley Scholarships.—Three Open Scholarships in Chemistry of the value of about £96 each are awarded annually in September.

Bowen Scholarship.—One Open Scholarship in Metallurgy of the value of about £96 is awarded annually in September.

For particulars apply to the Registrar.

Excursions.

During previous Sessions permission has been obtained to visit some of the great factories in or near Birmingham

in which chemical and metallurgical industries are carried on. Students have thus had most valuable opportunities of gaining a practical acquaintance with some branches of Applied Science. The privilege thus courteously granted by several manufacturers will, it is hoped, be enjoyed in every future Session. The excursions will be conducted by the Professor or Lecturers.

CITY OF BRADFORD TECHNICAL COLLEGE.

DEPARTMENT OF CHEMISTRY AND DYEING.

Head of Department—Prof. W. M. Gardner.

Lecturers in Chemistry—B. North, A.R.C.Sc. (Lond.);

L. L. Lloyd, Ph.D.; S. F. Stell, F.C.S.

Demonstrators in Chemistry—A. H. M. Wheatley and G. Sargent.

Lecturer in Physics—J. A. Tomkins, A.R.C.Sc. (Lond.).

Demonstrator in Physics—E. B. Walker.

Lecturer in Dyeing—A. B. Knaggs, F.C.S.

Demonstrator in Dyeing—L. Min kin.

Lecturer in Gas Manufacture—W. Cranfield.

Lecturer on Botany, Biology, and Pharmacy—W. West, F.L.S., Ex. Pres. Yorkshire Naturalists' Union.

The following courses of instruction are provided:—

I. *General Chemistry Course*, extending over four years, including Lectures in Inorganic, Organic, and Technological Chemistry, Principles of Analysis, Technical Analysis, Physical Chemistry, Crystallography, Fuels, Lighting and Ventilation, Physics, Mathematics, Mechanics, with Laboratory work in Chemistry, Physics, Bacteriology, and Microscopy.

II. *Chemistry and Dyeing*, extending over four years. Includes most of the above subjects, along with Lectures and practical work in Dyeing, Colour matching, &c.

III. *Chemical Engineering*. Three years' course, preparing Students for positions in Chemical Works, Sewage Works, &c.

IV. *Sanitary Science*. One year's Course, recognised by the Sanitary Institute as preparing for their certificate examination. Subjects: Chemistry, Physics, Sanitary Engineering, Sanitary Law, Building Construction, Drawing, Physiology, and Bacteriology.

V. *Dyeing*. Extending over one or two years.

VI. *Textile and Dyeing*. Arranged for those Students who desire to study the two subjects simultaneously.

VII. *First Professional Examination, Conjoint Medical Board (M.R.C.S., L.R.C.P.)*, London.—Attendance at the College and College Certificates in Chemistry, Physics, and Biology are recognised by the Conjoint Board for Medical Studies as a qualifying curriculum.

VIII. *General Pharmaceutical Course*. Prepares for the Minor and Major Pharmaceutical Examinations. Each extends over two years on three half-days per week, and includes Chemistry and Physics, Botany, Biology, Materia Medica, Pharmacy, and Dispensing.

IX. Attendance at the College Courses and College Certificates in Chemistry, Physics, Animal Biology, and Botany are recognised by the Conjoint Board for Medical Studies.

ROYAL AGRICULTURAL COLLEGE, CIRENCESTER.

CHEMICAL DEPARTMENT.

Professor—Prof. E. Kinch, F.C.S., F.I.C.

Assistant—W. James.

Systematic courses of Lectures are given on the various branches of Chemistry in its relation to Agriculture, illustrated by experiments, and by the collections in the College Museum. They comprise the laws of Chemical Combination and the general Chemistry of mineral bodies, and of the more frequently occurring bodies of organic origin, with the relationships of their leading groups; and, finally, the applications to practical operations of the Chemistry of the atmosphere, of soils and manures, of vegetation, of stock feeding, and of the processes and products of the dairy.

In the Laboratory practical instruction is given in

the construction and use of apparatus and in Chemical manipulation and analysis, both qualitative and quantitative. After studying the simple operations and the properties of the commonly occurring substances, the Students are taught to analyse a series of compounds, and apply the knowledge thus obtained to the analysis of manures, soils, waters, feeding stuffs, dairy products, and other substances met with in the ordinary course of Agricultural practice. Chemico-agricultural researches are undertaken by the senior Students under the direction of the Professor and his Assistants.

THE UNIVERSITY OF LEEDS.

Professor of Chemistry—Arthur Smithells, B.Sc., F.R.S.
Professor of Organic Chemistry—Julius B. Cohen, Ph.D., B.Sc.

Assistant Lecturers and Demonstrators—T. S. Patterson, Ph.D., and H. M. Dawson, B.Sc., Ph.D.

Demonstrators—C. E. Whiteley, M.Sc., and W. Lowson, B.Sc., F.I.C.

The Session begins October 5, 1904.

Lecture Courses.

1. General Course of Chemistry.—Monday, Wednesday, and Friday, at 11.30 a.m. Fee for the Course, £4 4s.

2. Advanced Inorganic Chemistry.—Metals. Monday, Wednesday, and Friday, at 9.30 a.m. Fee, £3 13s. 6d.

3. Advanced Inorganic Chemistry.—Non-metals. Tuesday, Thursday, and Saturday, at 9.30 a.m. Fee, £3 13s. 6d.

4. Organic Chemistry.—Tuesday, Thursday, and Saturday at 12 noon Fee £3 13s. 6d.

5. Honours Courses—

(a) Organic Chemistry.—Monday, Wednesday, and Friday at 12 noon in the First and Second Terms. Fee, £2 12s. 6d.

(b) History of Chemistry.—Monday, Wednesday, and Friday at 9.30 a.m. in the First Term. Fee, £1 11s. 6d.

(c) Physical Chemistry.—Tuesday, Thursday, and Saturday at 9.30 a.m. in the Second and Third Terms. Fee, £2 12s. 6d.

(d) Electro-chemistry.—One hour weekly. 31s. 6d.

Laboratory Courses.

The University Laboratory will be open daily from 9 a.m. to 1 p.m., and from 2 to 5 p.m., except on Saturdays, when it will close at 1 p.m.

Fees for the Session—Students working six days per week, £21; five, £18 18s.; four, £16 16s.; three, £13 13s.

Practical Course in Sanitary Chemistry.—Tuesdays and Thursdays from 2 to 5 from January to March. Fee, £5 5s.

Elementary Science for Teachers.—Saturdays, 9.30 to 12.30, for half the session. £2 12s. 6d.

Dyeing and Tintorial Chemistry Department.

Professor—Arthur G. Green, F.I.C.

Lecturer and Research Assistant—A. G. Perkin, F.R.S., F.I.C.

Assistant Lecturer—A. B. Steven, B.Sc.

The Courses extend over periods of three or four years, and are intended for those who wish to obtain a full scientific and practical education in the art of dyeing, &c. It is suitable for those who purpose in the future to take any part in the direction of the operations of dyeing or printing of textile fabrics, e.g., the sons of manufacturers, calico printers, managers, master dyers, &c.

Leather Industries Department.

Professor—H. R. Procter, F.I.C.

Assistant Lecturer and Demonstrator—F. Kopecky.

Demonstrator—Harold Brumwell.

The full Courses, which extend over a period of either two or three years, are suitable to all who intend to become Technical Chemists in the Leather Industry, or managers of important works, and are recommended to sons of tanners. The Courses include instruction in chemistry, a modern language, leather manufacture, and practical work in the Leather Industries Laboratory and Dye-house.

Agricultural Department.

Professor—R. S. Seton, B.Sc.

Lecturer in Agricultural Chemistry—C. Crowther, M.A., Ph.D.

The full Course occupies two years, and includes instruction in chemistry, physics, mathematics, geology, botany, forestry, engineering and surveying, and the principles of agriculture, as well as practical work in the various laboratories and out door agriculture.

Research Students are admitted to the University Laboratories on reduced terms.

Several valuable Scholarships are at the disposal of the University, viz., the Salt, Akroyd, Brown, Baines, Emsley, Craven, Wheatley, Leeds City Council, and Clothworkers' Scholarships, and one of the 1851 Exhibition Scholarships. The North, East, and West Ridings County Council's Scholarships are tenable at the University of Leeds.

UNIVERSITY OF LIVERPOOL.

Professor—J. Campbell Brown, D.Sc.

Lecturer on Organic Chemistry—A. W. Titherley, D.Sc., Ph.D.

Demonstrators and Assistant Lecturers—A. T. de Moulpied, M.Sc., Ph.D.; A. W. Titherley, D.Sc., Ph.D.; B. C. Burt, B.Sc.; and F. J. Brislee, M.Sc.

Assistant—H. H. Froyssell.

The Session commences October 1st.

Entrance Scholarship Examination takes place early in May each year.

The Classes meet the requirements of candidates for the Ordinary B.Sc. Degree, for Chemistry Honours, or for the M.Sc. or D.Sc. Degree in the University of Liverpool; for Degrees in Medicine of Liverpool, London, and Edinburgh; for the Pharmaceutical Diplomas; and for those studying Chemistry as a preparation for professional, technical, or commercial life. The Classes qualify for the Fellowship of the Institute of Chemistry of Great Britain and Ireland, and other Examination Boards.

Lecture Courses.

A. General Elementary Course on the principal non-metallic elements and the most important metals, the principles of Chemical Philosophy, and an introductory sketch of Organic Chemistry. Three Terms. Fee, £4.

Engineer's Course of Lectures with Practical Class. Two Terms. Fee, including Practical class, £4.

Pharmacy Courses: Junior, £3; Senior, £3.

Course B.—Metals and Non-metals. Fee, £3.

Course C.—Inorganic Chemistry. Fee, £3.

Course D.—Organic Chemistry. Fee, £3.

Course E.—Special Organic Subjects. Fee, £2.

Course F.—Physical Chemistry. Fee, £2.

Course G.—Advanced Physical Chemistry. Fee, £2.

Course H.—History of Chemistry and of Development of Modern Chemical Philosophy. Three Terms. Fee, £2.

Courses I.—Applied Chemistry and Metallurgy: Lectures on Technology are given in connection with Laboratory work at hours to be arranged. The subjects are varied in different years. (1) Alkali and Allied Manufactures. (2) General Principles of Metallurgy. (3) Iron, Steel, and Aluminium. (4) Copper, Lead, Silver, and Gold, and other Metals. (5) Distillation of Coal and Tar Industries. (6) Fuel and Gas. (7) Chemistry Applied to Sanitation. (8) Technical Gas Analysis. (9) Electro-chemistry. Three terms. Fee, each course £1 10s.

Practical Classes.

(1) Preliminary. (2) Intermediate: Qualitative Analysis of Inorganic Substances and of some of the more common Organic Substances; preparation of Inorganic Compounds. (3) Revision Class. (4) Senior: Practical Organic. (5) Practical Exercises on Technology, Pharmaceutical Chemistry, Sanitary subjects, Examination of Water and Air, &c.

Chemical Laboratory.

The Chemical Laboratories recently enlarged provide accommodation for every kind of chemical and metal-

lurgical work and research. They include thirty rooms devoted to the study of Chemistry and Metallurgy. Separate rooms are provided for Organic Work, Quantitative Analysis, Water Analysis, Gas Analysis, Photometry and Photography, Electro-chemical Work, Metallurgy Laboratories, a Research Laboratory, and a Museum. New stores for students' apparatus and chemicals have also been built and placed in charge of a skilled dealer.

Students desirous of gaining a thorough theoretical and practical acquaintance with Technical Chemistry, or who intend to adopt Chemical work as a profession, must devote three or four years to special study, for which a full curriculum is provided.

TABLE OF FEES.

Per Week.	One Term, Three Months.	Three Terms, One Session.
One day	£4	£7
Two days	5 10s.	10
Three days	7	13
Whole week	10 10s.	21

Pharmaceutical Course (see special syllabus).

D.P.H. Course (see special syllabus).

Course for Dental Degree (see special syllabus)

Technological Curriculum.

Preliminary Year.—Chemistry, the Elementary Course. Practical Classes 1 and 2. Mathematics, or Mechanics, Elementary Engineering, Drawing, and Design (in this or one of the following years). German. Or, the University Preliminary Course and Examination may be taken.

First Year.—Chemistry—Courses B and D; Chemical Laboratory three days per week; Technological Chemistry, Course I. Physics, with laboratory work, one day per week. Mathematics (intermediate). German. Engineering, First Year Course, Autumn and Lent Terms. Intermediate B.Sc. Examination may be passed.

Second Year.—Chemistry, Lecture Courses C and F, Technological Chemistry, Course I. Chemical Laboratory, four days per week. Engineering, Mathematics, or Physics (Advanced). The Final Examination for the B.Sc. Degree of the University of Liverpool, or the Intermediate Examination of the Institute of Chemistry, may be taken.

Third Year.—In the third year the student should begin to specialise. The following are possible alternatives:—1. Courses G, H, and I. Any other Courses omitted in a previous year. Laboratory, five days per week. The Degree of B.Sc. in the Honours School of Chemistry may be taken. 2. Metallurgical Classes. Metallurgical Laboratory, two days per week. Chemical Laboratory, Gas Analysis, and Electro-chemistry, two days per week. Physical and Electrotechnical Laboratory, one day per week. 3. Courses F, H, and I. Physics (Senior Course). Chemical Laboratory, four days per week. Physical Laboratory, one day per week. 4. Courses F and I, and a course on Chemistry applied to manufacturing operations. Chemical Laboratory, three or four days per week. Engineering Laboratory and Electrotechnical Laboratory, one day per week.

Students may finally choose a special subject either of research or of applied Chemistry. The Final Examination for the Associateship of the Institute of Chemistry may be taken after 1, 2, or 3. Those who have taken the Ordinary Degree of B.Sc. may pass the M.Sc. Examination in any subsequent year.

The Sheridan Muspratt Chemical Scholarship of £50 per annum, tenable for two years, will be competed for in December, 1905, on an Examination in subjects which are included in the first two and a half years of the above curriculum. Candidates should send in their names to the College Secretary not later than November 15, 1905. Other Scholarships, Entrance Scholarships, and Free Studentships are also available to Students.

Evening Classes.

Classes, including laboratory work, will be held during the winter.

The Prospectus containing particulars may be obtained from the Secretary, University of Liverpool.

**DURHAM COLLEGE OF SCIENCE,
NEWCASTLE-ON-TYNE.**

Professor of Chemistry—P. Phillips Bedson, M.A., D.Sc., F.I.C., F.C.S.

Lecturer in Chemistry—F. C. Garrett, M.Sc., F.C.S.

Lecturer in Agricultural Chemistry—S. Hoare Collins, F.I.C., F.C.S.

Assistant Lecturer and Demonstrator—J. A. Smythie, M.Sc., Ph.D.

First Year Courses.—1. *General Course*.—This Course of Lectures will extend over the three terms of the Session, and is intended to serve as an introduction to the Science. The Lectures will be of an elementary character, and whilst framed to meet the requirements of First Year Students will also be serviceable to such as intend pursuing Chemistry in its various applications in the arts and manufactures, as, for instance, Brewing, Metallurgy, the Manufacture of Soda, Soap, Glass, &c. The subjects treated will include an exposition of the Principles of Chemistry, and a description of the preparation and properties of the chief Elementary Substances, both metallic and non-metallic, and their more important native and artificial compounds. The class will meet on Mondays, Wednesdays, and Fridays, at 11 a.m., and will commence on Wednesday, October 7 h. Fee, £3 10s. for the Session.

2. *Special Course*.—More advanced than the above. Wednesdays and Fridays, 11 to 12. Fee, £3 10s. for Session.

Second Year Courses.—The Lectures for the second year students consist of a course of Lectures on Organic Chemistry, and a course of Lectures on Inorganic Chemistry. The class on Organic Chemistry will meet on Tuesdays and Thursdays at 11 a.m., and will commence on October 6th. The class for Inorganic Chemistry meets at 11 a.m. on Mondays. Fee for Session, £3 10s.; for Inorganic alone £1 10s.; and for Organic alone £3.

Third Year Courses.—Advanced Classes are held for the study of Inorganic, Organic, and Theoretical Chemistry. Fee for the course, £3 10s.

A Lecture Course in Analytical Chemistry will be given on Fridays, at 9.15 a.m.

Metallurgy and Assaying.—Lecturer, Professor Louis, M.A., F.I.C., F.C.S.; Demonstrator, G. H. Stanley, A.R.C.M. A Metallurgical Laboratory is provided, in which instruction is given in the ordinary processes of Dry Assaying, and in the preparation and analysis of Alloys, &c. Fees as for Chemical Laboratory.

Agricultural Chemistry.—The instruction in this branch of Chemistry will consist of a series of Lectures and of special practical work in the Chemical Laboratory. Students will be expected to have a knowledge of Elementary Chemistry, such as may be obtained by attending the General Course.

The Lecture Course in Agricultural Chemistry is arranged for two days a week throughout the Session. Fee, £3 10s.

Practical Chemistry.—The Laboratory is open from 10 a.m. to 1 p.m., and from 2 to 5 p.m., except on Saturdays, when it closes at 1 p.m. *Laboratory Fees*.—Students working two days, £2 10s. per term, £6 per session; one day per week, £1 10s. per term, £3 10s. per session.

Courses of Study.—Students will be divided into two classes:—(1) Regular, or Matriculated Students, who are also Members of the University of Durham; and (2) Non-Matriculated Students. Regular Students will be required to follow such a course of study in the subject professed in the College as will enable them to pass the Examinations for the degree of Bachelor in Science of the University of Durham. Non-Matriculated Students will attend such classes as they may select. Every candidate for admission as a matriculated student must pass an examination on entrance, in the following subjects:—

Arithmetic; English Essay; Geometry; the subject-matter of Euclid, Books I., II., III.; Algebra, up to and including Quadratic Equations. Also any two of the following:—English Language; Latin, including Grammar and Easy Sentences; Greek; French; German; Geography. The next examination commences on September 26. Names to be sent in at least ten days before this date. Registered students in medicine are exempted from this examination, or students who produce a certificate of having passed either of the three following examinations:—1. The first examination for the Degree of B. Litt. 2. Durham Examination for certificate of proficiency in General Education, held in March and September. 3. Durham Examination for Students in Arts in their first year, or any examination of a similar nature that may be accepted by the Council.

Bachelorship in Science.—Every candidate for the Bachelorship in Science will be required to satisfy the examiners in Mathematics, Physics, Chemistry, and either Geology or Natural History—in an examination to be held at the end of the candidate's first year, and at the end of the third year in an examination in one chief and two auxiliary subjects. For details of the subjects the College Calendar should be consulted. Candidates may qualify for the degree of B.Sc. by attending special courses in Agriculture, Engineering, and Mining, and passing the several examinations.

Exhibitions.—Three Exhibitions of the value of £25, £15, and £10 respectively will be awarded in September next to Candidates desirous of attending the first year course of study in the College.

The examination will be held at the College, and will commence on Monday, September 26th.

Evening Lectures.—Courses of Evening Lectures will be given, with a Practical Class for Laboratory instruction.

Several valuable Scholarships are available for students, including the Johnston Chemical Scholarship of the value of £60 for one year, which is open to Bachelors of Science of any British University; the examination for this Scholarship will be held during the week commencing September 26th. Candidates should send in their names to the Secretary on or before September 19th.

**OWENS COLLEGE,
THE VICTORIA UNIVERSITY OF MANCHESTER.**

Professor and Director of the Chemical Laboratory—Harold B. Dixon, M.A., F.R.S.

Professor of Organic Chemistry—W. H. Perkin, Ph.D., F.R.S.

Demonstrators and Assistant Lecturers—George H. Bailey, D.Sc., Ph.D.; W. A. Bone, D.Sc.; D. L. Chapman, B.A.; Norman Smith, B.Sc.; F. V. Darbishire, B.A., Ph.D.; C. H. Burgess, B.Sc.

Demonstrator in Organic Chemistry—D. T. Jones, B.Sc. *Lecturer in Technical Organic Chemistry*—Jocelyn F. Thorpe, Ph.D.

Lecturer in Metallurgy—Dr. Bone. *Lecturer in Electro-Chemistry*—R. S. Hutto, B.Sc.

The Session begins on October 4, 1904.

The instruction is given by means of Experimental Lectures and Tutorial Classes. The Chemical Classes form part of the Courses for Chemistry in the University.

Chemistry Lecture Courses.—*General Chemistry Course*.—Tuesdays, Thursdays, and Saturdays, at 9.30, during the two Winter Terms.

Introduction to Organic Chemistry.—Wednesdays and Fridays, at 9.30, during Lent Term.

These courses are intended for Medical Students and others beginning the study of chemistry.

First Year Honours Course.—Mondays, Wednesdays, and Fridays, 11.30 a.m., during the two Winter Terms. The Non-Metals.

Second Year Honours Course.—Tuesdays, Thursdays, Saturdays, 11.30 a.m., during the two Winter Terms. The Metals.

Third Year Honours Course.—At times to be arranged. Physical Chemistry.

Organic Chemistry (General).—Mondays and Fridays, 9.30, during two Winter Terms.

Organic Chemistry (Advanced).—Tuesdays and Thursdays, 9.30, during the two Winter Terms.

History of Chemistry and Chemical Philosophy.—Wednesdays, 9.30, during the Session.

CHEMICAL LABORATORIES.—These have again been extended. Two large rooms have been added to the main laboratories; one for Inorganic and one for Organic work. These will connect the present buildings to the Schunck Laboratory. The Laboratory and Chemical Library belonging to the late Dr. E. Schunck, F.R.S., left by him in 1902 for the use of the Owens College, has been re-erected in Burlington Street. The Schunck Laboratory is to be devoted to research work.

The Chemical Laboratories are open daily from 9.30 a.m. to 4.30 p.m., except on Saturdays, when they are closed at 12.30 p.m.

METALLURGY.—*Lectures:* (A) The Metallurgy of Copper, Lead, Silver, Gold, Zinc, and Antimony; and (B) the Metallurgy of Iron and Steel.

The Metallurgical Laboratory, which is open every day in the week, has been greatly enlarged and re-equipped with a view to research work on the structure and properties of Steel and other Alloys, and the Chemistry of Fuel and Gases.

ELECTRO-CHEMISTRY.—In connection with the John Hopkinson Memorial Laboratory, rooms have been fitted for the study of Electricity in its applications to Chemistry. There is a complete equipment for Electro-chemical and Electro-metallurgical work. Demonstrator and Assistant Lecturer in Electro-technics, Robert Beattie, B.Sc. (Durham). Demonstrator and Assistant Lecturer in Electro-chemistry, R. S. Hutton, M.Sc. (Vic.).

Courses for B.Sc. Degree.—To qualify for the B.Sc. Degree of the Victoria University, Students have to attend a prescribed course of study extending over three years, and to pass the Matriculation Examination of the University either on entering or at the end of a year's Course.

The Honours Course of Chemistry is as follows:—First year: First year Honours Lectures; Mathematics (3 hours a week); Physics (3 hours a week); a Language (3 hours a week); Chemical Laboratory (3 days per week). Second year: Second year Honours Lectures; General Organic Lectures; Applied Chemistry or Metallurgy Lectures; Physics Laboratory (1 day per week); Chemical Laboratory (3 days per week). Third year: Third year Honours Lectures; Honours Organic Lectures; History of Chemistry Lectures; Chemical Laboratory (5 days per week).

The following awards are made to successful Students in the Honours Examination:—A University Scholarship of £50; a Mercer Scholarship of £25. A University Fellowship of £100 is awarded annually among the Graduates in Science for the encouragement of Research. Among the College Scholarships open to Chemical Students are the Dalton Chemical Scholarship, £50 per annum for two years; the 1851 Exhibition Scholarship, &c.

Schunck Fellowship.—A Fellowship for Chemical Research will be offered during the Session 1904-5 under the Schunck endowment, a portion of the income arising from which is at present used for providing expensive material required in research work. Properly qualified Students may be appointed to Research Studentships, which entitle the holders to work in the laboratories under reduced fees.

Applied Chemistry.

First Course.—Sulphuric Acid and Alkali Manufactures. General Principles of Chemical Engineering.

Second Course.—The Chemistry of Fuel. The Manufacture of Illuminating Gas and Gaseous Fuel.

Third Course.—Natural and Artificial Dye-stuffs, and the Principles of Dyeing and Printing.

Certificates in Applied Chemistry.

The course extends over a period of three years, and comprises systematic instruction by means of lectures and practical work in the laboratories.

Before admission to the first year's course students are required to give such evidence of elementary knowledge of Mathematics and Chemistry as shall be considered satisfactory by the Senate.

The first year's course is the same for all students working for the certificate.

In the second and third years a choice may be made between Inorganic and Organic Chemistry. By this division of the subject a student wishing to apply himself specially to the inorganic side of the science, may attend during his second year the Honours course in Metals, and courses on Geology or Mineralogy, and during his third year, courses on Metallurgy and on Geology or Mineralogy; while a student wishing to apply himself specially to the organic side of the science, may attend during his second and third years the Courses on Organic Chemistry, and courses on the Coal Tar Colours and on Dyeing and Printing.

Part of the Laboratory practice in the second and third years will consist in the examination and analysis of raw materials, products from chemical works, &c., in connection with the special courses of lectures on Applied Chemistry. In the Chemistry and Physical laboratories the practical work in the second year will be arranged in accordance with the branch of Chemistry selected by the candidate.

In the third year the student, if sufficiently advanced, will be set to work on some analytical process or problem in Applied Chemistry, under the direction of the teaching staff. For further particulars apply to the Registrar, Mr. S. Chaffers.

UNIVERSITY COLLEGE, NOTTINGHAM.

DEPARTMENTS OF CHEMISTRY AND METALLURGY.

Professor of Chemistry.—F. Stanley Kipping, Ph.D., D.Sc., F.I.C., F.R.S.

Demonstrators of Chemistry.—R.M. Caven, D.Sc., F.I.C.; A. Sator, Ph.D., B.Sc.; and G. Sand, Ph.D., M.Sc.

The Classes of the College are open to students of both sexes above sixteen years of age.

The Session commences on October 3rd, for both Day and Evening Classes.

Lecture Courses.—The Chemistry Day Lectures extend over three years. In the first year a student enters for the course on Elementary Chemistry. In his second year he attends Lectures on both Inorganic and Organic Chemistry. In his third year he attends courses on Advanced Organic Chemistry, Physical Chemistry, and Advanced Inorganic Chemistry.

The fees for the Day Lectures and Classes are as follows: First year, two Lectures per week, 15s. per term. Second year, three Lectures per week, 22s. 6d. per term. Third year, four Lectures per week, 30s. per term.

Demonstrations and Lectures on Analytical Chemistry are given, and Chemical Calculation and Tutorial classes are also held. Various short courses of lectures on special subjects are delivered during the Session.

Students may qualify themselves by attendance at these lectures and classes for the Examinations of the Universities of London, Cambridge, or Oxford, and for the Medical Examinations of the Royal College of Surgeons and of the Universities of Cambridge and Edinburgh; they may also obtain instruction in Chemistry for technical or other purposes, and can enter for a full Chemical Engineering Curriculum. Special attention is given to the requirements of candidates for the Associateship of the Institute of Chemistry.

Practical Chemistry and Metallurgy.—The Chemical and Metallurgical laboratories are open every day from 9 to 5, except on Saturday, when the hours are from 9 to 1; also on Tuesday and Thursday evenings from 7 to 9. Each Student works independently of other Students at a course recommended by the Professor. Instruction is given

in general Chemical Manipulation, in Qualitative and Quantitative Analysis, and in the methods of Original Chemical Investigation and Research; Students are also enabled to work out the applications of Chemistry to Pharmacy, Metallurgy, Dyeing, Agriculture, Brewing, Iron and Steel, Tanning, and other Manufacturing Processes. Fees for day students: For one term, £7; for the session, £18; for six hours weekly 40s., and 15s. extra for each additional hour per week. For evening students, 10s. for two hours per week, three hours 15s., four hours 20s., per term.

Research Work.—Students or others wishing to undertake research work in pure or Applied Chemistry will be afforded every facility for doing so and may be admitted at reduced fees. The Laboratories are fully equipped with apparatus and chemicals necessary for such work.

Courses of Technical Chemistry Lectures are also given on Engineering, Dyeing and Bleaching, Brewing, Plumbing, Bread-making, Gas Manufacture, and on other processes of applied Chemistry.

Pharmaceutical Students are provided with Lectures and Laboratory work suitable for the preparation for the Minor and Major Examinations.

Evening Classes.—Evening Lectures and Laboratory instruction will be given in Pure and Applied Chemistry, and the laboratories are open for practical work on Tuesday and Thursday evenings from 7 to 9. Fee for each Lecture Course, 5s.; for each Laboratory Course, 10s.

Full information concerning all College Classes is given in the College Prospectus, price one penny.

UNIVERSITY COLLEGE, SHEFFIELD.

Professor of Chemistry—W. P. Wynne, D.Sc., F.R.S.
Lecturer—G. Young, Ph.D., F.R.S.E.

The Session will commence on October 5th.

Matriculation Course.—Tuesday and Friday 10—11. Fee, £2 12s. 6d., and three hours per week Laboratory work.

Intermediate Course.—Monday and Thursday, 10—11 a.m.; Saturday, 10—11 (2 Terms), £3 13s. 6d., and nine hours per week Laboratory work.

B.Sc. Course.—Monday, Tuesday, and Friday, 10—11, and another hour to be arranged, £5 15s. 6d., and twelve hours per week Laboratory work.

Organic Chemistry.—Elementary: Saturdays, 10—11, fee £1 1s. Advanced: Tuesdays and Fridays, 10—11, fee £2 12s. 6d.; Tuesdays and Fridays, 12—1, fee £2 12s. 6d.; another hour to be arranged, fee £1 11s. 6d.

Physical Chemistry.—Monday, 10—11, fee £1 11s. 6d.

History of Chemistry.—Tuesday, 11—12, fee £1 11s. 6d. A course of Lectures is arranged for Medical Students, with a special class in Qualitative Analysis.

Laboratory.—Working hours to be arranged between Professor and Students.

Sessional Fees for Day Students:—Six hours per week, £5 5s.; Nine, £7; Twelve, £8 8s.; Eighteen, £11 5s.; Twenty-four, £14; Thirty-two, £17.

Students joining the Laboratory at Christmas will be charged two-thirds and at Easter one-third of the Fees for the whole Session.

Fees for short periods (working thirty-two hours per week):—For one month, £3 3s.; two months, £5 5s.

A course of Elementary Practical Physics and Practical Chemistry, which will meet the requirements of candidates for the Diploma of Public Health will be held during the Michaelmas and Lent terms. Fee £5 5s.

An arrangement has been entered into with the Board of Education, South Kensington, which will enable Science Teachers to work in the Chemical Laboratory for three, six, or twelve hours a week on payment of one-quarter of the usual fee, the Board being willing to pay the remainder under certain conditions, of which full information may be obtained on application to the Registrar.

Evening Classes.—Lectures, Wednesday, 8—9. Laboratory instruction, Wednesday, 6—9. Sessional Fee, Lecture Class and Laboratory, on Wednesday evening, £1 10s. Fee for one term, 17s. 6d.

DEPARTMENT OF METALLURGY

Professor of Metallurgy—J. O. Arnold. This Department has been equipped to meet the requirements of the local industries. The Laboratory is fitted with the most modern apparatus for metallurgical analysis, more especially with appliances for the rapid and accurate chemical examination of Iron and Steel, Fuel, and Refractory materials. It also contains a complete pyrometric installation, and a laboratory for the study of the micrographic analysis of metals fully equipped with specially designed microscopes by Ross, polishing tables, etching appliances, incandescent light for evening work, &c. The School is now the most complete of its kind for teaching the practical manufacture, the chemical constitution, and the physical properties of Steel. Special attention is given to the determination of the microscopic constituents of Steel. Although the chief industry of the district occupies the central position in the course of instruction, general metallurgy is not neglected, but is dealt with in a separate syllabus, dealing with metals (other than iron and steel) used in the arts. Students are thus enabled to select and at once enter upon a course of scientific metallurgical training of immediate practical utility. They may take up and work through any portions of the course, but certificates will be granted only to those who follow the prescribed courses, and pass the necessary examinations. Lectures on Iron and Steel Manufacture, on Fuel and Refractory Materials, and on General Metallurgy. Practical Metallurgy:—Laboratory, Furnaces, Foundry, and Testing Machine Course; Practical Course of Metallurgy other than Iron and Steel; Practical Fuel Course for Students engaged in Collieries or Gas-Works.

A new steel works has recently been erected in connection with the Sheffield College at a cost of about £10,000. The works include a two ton open-hearth furnace, a one ton Bessemer plant, and a four-hole crucible melting plant. The works is also provided with a hammer capable of dealing with four-inch ingots. Differential annealing furnaces, oil-brightening and lead-tempering tanks will constitute part of the new plant. Additional laboratory accommodation is attached to the works, viz., chemical laboratory for staff, chemical laboratory for post graduate students, together with a complete magnetic laboratory for hysteresis, &c.

UNIVERSITY COLLEGE, DUNDEE.

UNIVERSITY OF ST. ANDREWS.

Professor of Chemistry—James Walker, Ph.D., D.Sc., F.R.S.

Assistant Lecturers—J. S. Lumsden, Ph.D., D.Sc., and J. K. Wood, D.Sc.

Lecture Assistant and Laboratory Steward—J. Foggie, F.C.S.

The Winter Session begins on October 11th, and ends on March 15th. The Summer Session extends from the middle of April to the end of June.

The *Junior Lecture Course on Systematic Chemistry* is given daily during the Winter Session, and embraces the Elements of Inorganic and of Organic Chemistry.

Advanced Courses, of about fifty lectures each, will be given during the year as follows:—

Organic Chemistry; Inorganic Chemistry, including the more important technological applications; Theoretical and Physical Chemistry; Bleaching and Dyeing, including the Chemistry of the Textile Fibres.

Practical Instruction in all of the above branches will be given in the Laboratories and Dye-house. Special facilities are afforded to Research Students.

UNIVERSITY OF ABERDEEN.

CHEMISTRY.

Professor—Francis R. Japp, M.A., LL.D., F.R.S.
Demonstrators—A. N. Meldrum, D.Sc., and John Alexander, M.A.

I. General Lecture Course (100 Lectures).—Daily during the Winter Session. The subjects treated of include (1)

The Laws of Chemical Combination and the General Principles of Chemistry; (2) Non-metallic and Metallic Elements, and their Compounds; (3) Organic Chemistry; (4) Applications of Chemistry to the Arts and Manufactures. Fees, for first attendance, £4 4s; for subsequent attendance, £3 3s. A Tutorial Class (without fee), conducted by the Senior Demonstrator, is held in connection with this course.

II. *Special Lecture Course on Organic Chemistry* (50 Lectures).—Daily during the Summer Session. Fee, £3 3s.

III. *Practical Course for Medical Students*.—This course, which occupies five hours a week during the Summer Session—in all fifty hours—is devoted to practice in Elementary Qualitative Analysis. Fee, £4 4s.

IV. *Chemical Laboratory*.—The Laboratory is open to Students daily from 9 a.m. to 5 p.m. Each Student on entering is allowed to arrange his hours of work so as to suit his own convenience, but must adhere to these hours when once fixed. The Laboratory instruction includes: (1) General experiments; (2) Preparations; (3) Qualitative analysis; (4) Quantitative analysis: gravimetric, volumetric, and gasometric. Fee, £4 4s. a session. A certain number of free places are available, on the recommendation of the Professor, and subject to the approval of the Senatus, for research students.

V. *Physical and Advanced Inorganic Chemistry* (30 Lectures).—In connection with the Laboratory work, three Lectures a week on Physical Chemistry and selected portions of Advanced Inorganic Chemistry are delivered during the Winter Session by the Lecturer, Dr. A. N. Meldrum. Fee, £2 2s.

Agricultural Chemistry.

Lecturer—James Hendrick, B.Sc., F.I.C.

This course is given during the Winter Session, and includes both Lectures and Laboratory work. The Lectures deal with the chemistry of the atmosphere, the soil, manures, and foods. The physiological chemistry of plants and animals, the composition and manurial requirements of crops, and dairy chemistry, are also treated of. The Laboratory work is primarily intended to accompany and illustrate the Lectures. Exercises dealing with the properties and composition of soils, manures, feeding stuffs and waters, and with the impurities and adulterations of these, occupy much of the time given to practical work. The fee for the whole course—lectures and practical work—is £4 4s.

UNIVERSITY OF EDINBURGH.

DEPARTMENT OF CHEMISTRY.

Professor—Alex. Crum Brown, M.D., D.Sc., F.R.S.

Lecturers—L. Dobbin, Ph.D.; H. Marshall, D.Sc.; and W. W. Taylor, M.A., D.Sc.

The working terms are—Winter Session, from middle of October to middle of March; Summer Session, from beginning of May to middle of July.

Lecture Courses.—During the Winter Session a General Course of Chemistry for medical and science students is given by the Professor. The class meets daily; fee £4 4s. An Advanced Course of twenty-five lectures is also given in the Winter Session; fee, £2 2s. An Intermediate Course of Organic and Advanced Inorganic Chemistry is held in summer; fee, £2 2s. There is also a class on History of Chemistry or Chemical Theory, by Dr. Dobbin; fee £1 1s.; and a class on Mineralogy and Crystallography, by Dr. Marshall; fee, £2 2s. All these Lectures, except the General Course, are now open to women.

In addition to the above, Lecture Courses are from time to time given by the Assistants on particular branches of Organic and Inorganic Chemistry. These Lectures are free to Laboratory Students.

Laboratories.—Practical classes for Medical Students meet during the Winter Session and in the Summer Session. (Fee, £3 3s.). The laboratories for analytical and advanced practical work are open daily from 9.30 till 4.30. (Fees: Whole Day—Winter Session, £10 10s.; Oct.-Dec., Jan.-March, or Summer Session, £5 5s. Half Day—Winter

Session, £6 6s.; Oct.-Dec., Jan.-March, or Summer Session, £3 3s. Preference will be given to students in the above order. Students who are not Matriculated may attend the Chemical Laboratory on payment of the entrance fee of 5s. in addition to the Laboratory fees. Full Courses of instruction are given in Analytical, Practical Organic and Inorganic Chemistry, including Gas Analysis, Physico-Chemical Measurements, Agricultural Chemistry, and Assaying. Facilities are afforded to advanced students who desire to undertake chemical investigations.

Various prizes and scholarships are attached to the laboratory and general class.

Graduation.—Two Degrees in Pure Science are conferred, viz., Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.).

Candidates for Degrees in Science, if not graduates (by examination) in Arts in one of the Universities of the United Kingdom or in a Colonial or Foreign University recognised for the purpose by the University Court, must pass a preliminary examination in (1) English; (2) Latin, Greek, French, or German; (3) Mathematics; (4) One of the languages Latin, Greek, French, German, Italian, not already taken under (2), or Dynamics. In the case of a student whose native language is other than European, the Senatus may, at the Preliminary Examination, accept such language as a substitute for a modern European language. The Senatus may also in such a case accept as an alternative to Latin or Greek any other classical languages, such as Sanscrit or Arabic.

The First B.Sc. Examination embraces Mathematics, or Biology (*i.e.*, Zoology and Botany), Natural Philosophy, and Chemistry. The Final B.Sc. Examination in Pure Science includes any three or more of the following subjects:—Mathematics, Natural Philosophy, Astronomy, Chemistry, Human Anatomy, including Anthropology, Physiology, Geology, including Mineralogy, Zoology, including Comparative Anatomy, and Botany, including Vegetable Physiology. In the Final Examination two written papers are set in each subject professed, the second of a higher standard than the first. Candidates must pass the first section in all, and the second section in at least one, of the subjects professed; the same regulations apply also to the Practical and Oral Examinations. Chemistry in this examination embraces Inorganic, including Mineralogical, Chemistry; Organic Chemistry; Chemical Crystallography; History of Chemistry. In the written papers a choice of questions is allowed, so as to adapt the examination to the various courses of advanced study which candidates may have selected. Practical Examination:—Complex Qualitative Analysis; Inorganic Preparations; Gravimetric and Volumetric Analysis. Each candidate taking the higher standard will also be examined on Organic Preparations, Ultimate Organic Analysis, and one of the following subjects, selected by himself:—Gas Analysis; Assaying; Physico-Chemical Measurements.

A candidate for the D.Sc. Degree must submit a thesis on original work done by him. The Thesis must be approved before the candidate is allowed to proceed to Examination. The candidate in Chemistry may be required to pass a searching examination in one of the following branches:—(1) The Chemistry and Chemical Technology of Inorganic Bodies, including Metallurgy; (2) Organic Chemistry; and to show a thorough practical acquaintance with chemical analysis in all its branches, and with the preparation of pure substances.

HERIOT-WATT COLLEGE, EDINBURGH.

Principal—A. P. Laurie, M.A., D.Sc., F.R.S.E.

Professor—John Gibson, Ph.D., F.R.S.E.

Assisted by the following Lecturers and Demonstrators:—Bertram D. Steele, D.Sc.; Archibald Boon, B.A., B.Sc.; Andrew F. King, F.I.C.; and Dr. Emil Westergaard.

The Session begins October 4th, 1904.

The curriculum of this College comprises both Day and Evening Classes, each department providing the higher general and technical education.

The Chemistry Course is designed to meet the wants of Manufacturing Chemists. The instruction consists of Courses in Chemistry, Physics, Mathematics, Engineering, and Mechanical Drawing, with Special Courses in Gas and Paper Manufacture, Brewing, &c., by Experts, in the fourth year. Special attention will be paid to Electro-chemistry. The Chemistry Classes are recognised by the University as qualifying for the B.Sc., in Chemistry, and are also recognised by the Institute of Chemistry.

Matriculation Fee, 5s.; Composition Fee for Engineering Courses, £12 12s. per Session; for Chemistry Courses, First Session, £12 12s.; Second Session, £12 12s.; Third Session, £15 15s.; Fourth Session, £15 15s. Full particulars are published in the Calendar of the College early in September.

GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

Professor of Chemistry—G. G. Henderson, D.Sc., M.A.
Professor of Technical Chemistry—T. Gray, D.Sc., Ph.D.
Professor of Metallurgy—A. Humboldt Sexton, F.C.S., F.R.S.E.

Also, Professors and Lecturers in the other leading branches of Pure and Applied Science and Technology.

Session opens Sept. 27. Entrance Examination Sept. 19. The main objects of this College are to afford a suitable education to those who wish to qualify themselves for following an industrial profession or trade, and to train teachers for technical schools. It was founded by an Order in Council, dated 26th November, 1886, according to a scheme framed by the Commissioners appointed under the provisions of the Educational Endowments (Scotland) Act, whereby Anderson's College, the Young Chair of Technical Chemistry in connection with Anderson's College, the College of Science and Arts, Allan's Glen's Institution, and the Atkinson Institution were placed under the management of one governing body.

The Diploma of the College is awarded to Day Students who have attended prescribed courses of instruction and passed the necessary examinations. The ordinary courses extend over three years, but arrangements are made for advanced students continuing their studies in special departments.

Complete courses of instruction are provided in both Day and Evening Classes.

Copies of the Calendar for 1904-1905 may be had from Mr. H. F. Stockdale, Secretary, 38, Bath Street, Glasgow, price by post, 1s. 4d. Prospectuses will be sent free.

UNIVERSITY OF ST. ANDREWS.

UNITED COLLEGE OF ST. LEONARD AND ST. SALVATOR.
Professor of Chemistry—T. Purdie, B.Sc., Ph.D., LL.D., F.R.S.

The Session begins on October 7th. A Competitive Examination, open to intending Students of Arts, Science, and Medicine, for thirty-five Bursaries, ranging in value from £40 to £100 each per annum, will be held on September 23rd and following days. Nineteen of these Bursaries are restricted to Men, one to Men or Women, and fifteen to Women, the latter being intended for women who at the conclusion of their Arts or Science Course will proceed to Medicine.

A Hall of Residence is provided for Women Students. Two Degrees in Science are conferred by the University of St. Andrews, viz., Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.), and Chemistry is also included in the curriculum for the M.A. Degree; the regulations will be found in the "University Calendar."

Lecture Courses.

Two distinct Courses of Lectures are given, each comprising at least one hundred meetings of the class.

First Year's Course.—This Class meets at 11 o'clock on five days in the week. The introductory lectures treat of the Nature of Chemical Action, the Classification of Substances into Elements and Compounds, the Phenomena of Oxidation, and the Composition of Air and

Water. The Laws of Chemical Combination and the Atomic Theory are next discussed, after which the more commonly occurring elements and inorganic compounds are described systematically. Elementary Organic Chemistry is also included in the Course.

The chemistry of manufactures is referred to only cursorily; special attention, on the other hand, is given to those parts of the science which are of general educational value, and as much of the theory of chemistry is introduced as is compatible with elementary treatment.

This course of instruction is intended to meet the requirements of the M.A., First Science, and M.B., Ch.B. Examinations, so far as Theoretical Chemistry is concerned.

Second Year's Course.—The first part of the Course is devoted to Organic Chemistry, and the second part to General and Physical Chemistry, the instruction in general being such as is required for the Final Science Exam.

Certificates are awarded on the results of examinations, and the "Forrester Prize" of about £10 is awarded to the best Student of the year.

Fee for the Session, for each Course, £4 4s.

Practical Chemistry.

The Laboratory is open daily from 9 a.m. to 4 p.m., except on Saturdays, when it is closed at 1 p.m. The work pursued in the Laboratory comprises:—

(1) The performance of experiments illustrative of the Principles of Inorganic and Organic Chemistry; (2) Qualitative and Quantitative Analysis; (3) Original Investigation. Each student pursues an independent course of study under the supervision of the Professor or Demonstrator, the nature of the work varying with the proficiency of the student and the particular object he may have in view. Suitable courses of instruction in Practical Chemistry are provided for candidates for the Examinations in Arts, Science, and Medicine.

The fee for the Ordinary Course of Practical Chemistry is £3 3s. and for the Advanced Course £5 5s.

QUEEN'S COLLEGE, BELFAST.

Professor—E. A. Letts, Ph.D., D.Sc., F.R.U.I., F.R.S.E., &c.

I.—*Chemistry.*—The lectures are delivered at 3 p.m., on the first five days of each week, and terminate at the end of March. The course is divided into three parts:—(1) Chemical Philosophy; (2) Inorganic Chemistry; (3) Organic Chemistry. Fee, £2.

II.—*Practical Chemistry.*—In this course the Students are instructed in the general methods of conducting Chemical Analyses. Fee, £3.

III.—*Laboratory Pupils.*—The Chemical Laboratory is open from November until the end of March, and from May 1st until the third week of July, on the first five days of the week, from 10 a.m. until 4 p.m. Students are admitted as working pupils on payment of a fee of £5 for the first period, or of £3 10s. for the second period (or for a single term).

The new Chemical Laboratories are now open, and are provided with all modern appliances. Special facilities are offered to those engaged in Research work.

Scholarships.—The following College Scholarships are awarded specially in connection with the schools of Chemistry and Physics:—Senior Scholarships in Chemistry alone awarded annually of £40, and tenable for one year. Andrews Studentship in Chemistry and Physics, value about £80 annually, and tenable for two years. 1851 Exhibition Scholarships: One of these Scholarships has hitherto been placed at the disposal of the College every two years, of the annual value of £150, tenable for two or under special conditions for three years.

The following Scholarships, &c., of the Royal University of Ireland are awarded in the same group of subjects (Chemistry and Physics):—At the B.A. Degree examination, First-class Exhibitions of £42 each and Second-class Exhibitions of £21. At the M.A. Degree examination, a Studentship of £100 per annum, tenable

for three consecutive years. Also a Junior Fellowship, tenable for four years, of the annual value of £200.

QUEEN'S COLLEGE, CORK.

Professor—Augustus Edward Dixon, M.D.

Demonstrator—Robert Elliott Doran, F.C.S.

The College Session will commence on October 18th, 1904, and end on June 10th, 1905. All classes are open to male and female students.

The courses in Chemistry, though designed primarily to meet the requirements of candidates proceeding to the Examinations in Arts, Medicine, and Engineering of the Royal University of Ireland, of the Medical Licensing Bodies of Dublin and Edinburgh, and of the Pharmaceutical Society of Ireland, can be specially arranged as required, so as to render them suitable to any particular course of study. The following courses are provided:—

Systematic Chemistry.

I. General Lecture Course; three terms. Inorganic Chemistry, Elementary Organic Chemistry, and Chemical Philosophy.

II. Advanced Organic Chemistry, and Chemical Philosophy.

Practical Chemistry.

III. Winter Course of Practical Analytical Chemistry; commencing early in January, 1905.

IV. Summer Course of three months' duration, for students of Medicine; ending about the third week in June.

V. Course for Pharmaceutical Students; held during the second and third terms.

Laboratory Work.

VI. The Chemical Laboratory is open daily from 10 to 4 o'clock, to Students entering for Special Courses of practical work in General Inorganic Chemistry, Qualitative and Quantitative Analysis, Organic Chemistry, or for the purpose of Original Investigation.

Scholarships, &c.—In addition to the Class Prizes given at the Sessional Examinations, the College awards a Senior Scholarship of the value of £40, for Chemistry and Physics (either of which may be taken as a limited course), and numerous Junior Scholarships in Arts, Medicine, and Engineering, of which chemistry forms a part, value from £20 to £24 each, annually. The Royal University of Ireland also offers Exhibitions in Chemistry and Physics, First-class value £42, and Second-class value £21, together with other prizes, e.g., a Studentship of £100 per annum, tenable for three years; and the 1851 Exhibition Scholarships, value £150, tenable for two, and, under certain circumstances, for three years, have from time to time been placed at the disposal of the College.

Full particulars as to Lectures, Fees, Scholarships, Exhibitions, &c., are contained in the Regulations extracted from the College Calendar, which will be supplied on application to the Registrar.

QUEEN'S COLLEGE, GALWAY.

Professor—Alfred Senior, Ph.D., M.D., F.I.C., F.C.S.

Demonstrator—Miss Rosalind Clarke.

Research Assistants—W. Sloan Mills, M.A., and Percy C. Austin, B.A.

The College Session commences in October and ends in June.

Chemistry is studied by attendance at Lectures, by work in the Laboratories, and by the use of the College Library. The Courses in the several faculties are arranged with a view to the requirements of the Royal University of Ireland, but are adapted also to those of other Universities and licensing bodies.

Lecture Courses. Faculty of Arts.—1. Second year's Course, Inorganic and the Elements of General Chemistry. 2. Third year's Course, Advanced Organic Chemistry. 3. Fourth year's Post-Graduate Course, Advanced General Inorganic and Organic Chemistry. *Faculty of Medicine.*—First year's Course, Inorganic and Elementary Organic Chemistry. *School of Engineering.*—First year's Course, Inorganic Chemistry.

Laboratory Courses. Faculty of Arts.—1. Second year's Course, Exercises in Inorganic Qualitative Analysis. 2. Third year's Course, Quantitative Analysis and other experiments to suit the requirements of individual Students. 3. Fourth year's Post-Graduate Course, Advanced Quantitative Analysis, Organic and Inorganic Preparations, and determination of their Physical and Chemical characters. 4. The Laboratories are also open to Students for work in other branches of Chemistry. *Faculty of Medicine.*—1. Second year's Course, Inorganic and Organic Elementary Qualitative Analysis, and the Chemical Examination of Urine. *School of Engineering.*—1. Second year's Course, Inorganic Qualitative Analysis.

A Scholarship in Chemistry is offered for competition each year of the value of £40, and Chemistry enters into the subjects required for numerous Scholarships in Arts, Medicine, and Engineering. The Royal Commissioners for the Exhibition of 1851 offer every two years a Science Research Scholarship of £150 per annum. This Scholarship has already been held by three Chemistry Students of this College.

For details as to Fees, Regulations as to Scholarships, and other particulars apply to the Registrar, from whom the Calendar, published in December, and the Extracts from Calendar, published in advance in July, may be obtained.

ROYAL COLLEGE OF SCIENCE, DUBLIN.

Professor of Chemistry—W. N. Hartley, F.R.S., D.Sc.

Lecturer on Organic Chemistry—(Vacant).

Senior Assistant—J. Holms Pollok, B.Sc.

The Royal College of Science supplies, as far as practicable, a complete course of instruction in Science applicable to the Industrial Arts, and is intended also to aid in the instruction of teachers for the local Schools of Science.

Diplomas are awarded in the Faculties of Engineering (Mechanical and Electrical), Applied Chemistry, Agriculture, and Natural Science. If accompanied by a certificate from the Professor of Chemistry, the Diploma of Associate of the Royal College of Science in the Faculty of Manufactures is recognised by the Council of the Institute of Chemistry of Great Britain and Ireland as qualifying candidates for admission to the practical examinations of the Institute.

The instruction in Chemical Science includes (1) General Chemistry; (2) Organic Chemistry; (3) Analytical and Experimental Chemistry; (4) Instruction in Chemical Research.

Fees payable by Non-Associate Students:—£2 for each separate Course of Lectures. For Analytical Chemistry and Research—£5 for three months; £9 for six months; £12 for the entire session. For Assaying—£5 for three months; £9 for six months; £12 for the entire session.

There are four Royal Scholarships of the value of £50 each yearly, with Free Education, including Laboratory Instruction, tenable for two years; two become vacant each year; they are awarded on the results of their examinations to Associate Students, not being Royal Exhibitioners, who have been a year in the College.

A limited number of Scholarships in Science and Technology are competed for each year. These Scholarships include free education for the full Associateship Course of three years and maintenance allowance of a guinea a week during the Session.

CHEMICAL LECTURES, CLASSES, AND LABORATORY INSTRUCTION.

CITY AND GUILDS OF LONDON INSTITUTE FOR THE ADVANCEMENT OF TECHNICAL EDUCATION.—The operations of the City and Guilds of London Institute are divided broadly into four branches: the educational work of three London Colleges, and of the Technological Examinations. Programmes of the London Colleges may be had on application to the Head Office of the Institute, Gresham College, Basinghall Street, London,

E.C., or from the respective Colleges. The Technological Examinations (Examinations Department, Exhibition Road, S.W.), are conducted once every year at various centres throughout the kingdom. Programme, with Syllabus of Subjects, &c., may be obtained of Messrs. Whittaker and Co., Paternoster Square, London, or through any bookseller, price 10d., net. — *City and Guilds Technical College, Exhibition Road.*—Professor of Chemistry, H. E. Armstrong, Ph.D., F.R.S. The object of this Institution is to give to London a College for the higher technical education, in which advanced instruction shall be provided in those kinds of knowledge which bear upon the different branches of productive industry, whether Manufactures or Arts. The main purpose of the instruction given is to practically demonstrate the application of different branches of science to various manufacturing industries. In order that this instruction may be efficiently carried out, the Institution, in addition to the lecture theatres and class rooms, is fitted with laboratories, drawing offices, and workshops; and opportunities are afforded for the prosecution of original research, with the object of the more thorough training of the students, and for the elucidation of the theory of industrial processes. The courses of instruction are arranged to suit the requirements of—1. Persons who are training to become Technical Teachers; 2. Persons who are preparing to enter Engineers' or Architects' offices, or Manufacturing works; 3. Persons who desire to acquaint themselves with the scientific principles underlying the particular branch of industry in which they are engaged. The Matriculation Examinations begin on Tuesday, September 20th, and the Winter Session opens on Tuesday, October 4th. *City and Guilds Technical College, Finsbury.*—Professor of Chemistry, Raphael Meldola, F.R.S. The operations of the Technical College, Finsbury, are divided into two distinct portions: Day Classes for those who are able to devote one, two, or three years to systematic technical education; Evening Classes for those who are engaged in industrial or commercial occupations in the daytime and who desire to receive supplementary instruction in the application of Science and of Art to the trades and manufactures in which they are concerned or employed. Each Professor is assisted by Demonstrators. Besides these there are Lecturers and Teachers in special subjects. An examination for the admission of Students will be held at the College on Tuesday, September 20th. Session begins October 4th. *South London Technical Art School.*—Classes in Modelling, Design, Drawing and Painting, House Decoration.

CITY OF LONDON COLLEGE, White Street, Moorfields.—Courses of Evening Lectures and Laboratory Practice in Chemistry and Physics. Session commences Oct. 3rd.

BATTERSEA POLYTECHNIC.—Principal, Mr. Sidney H. Wells, Wh.Sc. Inorganic, Organic, and Technological Chemistry, Mr. John Wilson, M.Sc. (Vit.), assisted by Mr. John L. White, M.Sc., Mr. H. Evans, and others. Session opens Sept. 26. Complete courses of instruction are given in Chemistry (Inorganic and Organic), together with Physics, Electricity, Engineering subjects, German, &c., for intending technological and works chemists. Certain of the Courses (Day and Evening) are recognised by the University of London in preparation for the B.Sc., for which examination (Pass and Honours) complete courses of instruction, under recognised teachers, are provided. Special Evening Courses in Paper Testing, Paper Making, Gas Manufacture, Gas Analysis, Oils, Fats, and Soaps, Chemistry of Building Materials, Chemistry of Foods, &c.

BIRKBECK COLLEGE, Breams Buildings, Chancery Lane.—Chemistry Courses conducted by Dr. J. E. Mackenzie prepare for various Examinations, the B.Sc. and M.B. Degrees of the London University, Conjoint Board, Pharmaceutical Examinations, Board of Education, &c. This Institution, which has now completed eighty-one years of educational work in the metropolis, com-

mences its new Session on Monday, October 3, when an opening address will be delivered by Dr. J. E. Mackenzie, on "The Influence of Pure Science on Progress." The Day and Evening courses of study, comprise the various branches of Natural Science, Mathematics, Classical and modern Languages, Economics, Commercial Subjects, Law, Mental Science, and Art. The courses provide for the Examinations of the University of London, in the faculties of Arts, Science, and Commerce, and also for those of the Conjoint Board, Civil Service, &c. The Report for the last session shows that during the year 71 students passed some University examination, while large numbers gained successes at other public examinations. The College has had many additions to its appliances in recent years, and the Physical, Chemical, Biological, and Metallurgical laboratories are very highly equipped. The Day classes provide courses in Chemistry, Zoology, Botany, Physics, Mathematics, and Geology for the Science Degrees of London University, and a complete course of instruction in Metallurgy and Mining. There are also Day classes in Latin, Greek, and modern Languages. The School of Art is open both day and evening. The Metallurgical laboratory has been extended and reorganised, and classes are held both in the day and evening. The Calendar supplies complete syllabuses of the classes and full information about the College. A Lecture or Entertainment is given in the Theatre every Wednesday evening.

BRITTON SCHOOL OF CHEMISTRY AND PHARMACY, 171, Brixton Road, London.—Principal, Dr. A. B. Griffiths, F.R.S. (Ed.). Lectures on Inorganic and Organic Chemistry, Physics, Botany, &c., for Pharmaceutical, Medical, and other students. The benches in the laboratory are fitted with every convenience. There are courses in Research Work. Full particulars as to fees, &c., may be obtained by writing to the Principal.

BOROUGH POLYTECHNIC INSTITUTE, 103, Borough Road (near the Obelisk).—Chemistry: Evening Lectures and Laboratory Work in Inorganic and Organic Chemistry (Session fees, per course, 10s. to 20s.). Day Practical class in Electro-chemistry, lecture on Friday evenings. Special Saturday Morning Class in Practical Chemistry (10s.); Dr. F. Mollwo Perkin, assisted by H. B. Law, B.Sc., and A. J. Hale. Electricity and Magnetism: Evening Lectures and Laboratory Work (Session fees, per course, 10s.), Dr. J. Henderson, assisted by H. Saunders. Special Evening Courses on Painter's Oils, Colours, and Varnishes. Session opens Monday, October 3, 1904.

SOUTH WESTERN POLYTECHNIC, Chelsea, S.W.—Principal, Sidney Skinner, M.A. Head of the Chemical Department, J. B. Coleman, A.R.C.S., F.I.C. Day and Evening Courses in Theoretical and Practical Chemistry and several branches of Applied Chemistry including Metallurgy, Assaying, &c. Systematic Courses are held for the Matriculation, Intermediate Science, and B.Sc. Examinations of the University of London. Prospectuses of Day and Evening Classes may be obtained from the Secretary, 1d. each, by post 3d. each.

THE GOLDSMITHS' INSTITUTE, New Cross, S.E.—Lectures and Practical Classes in General Chemistry and Photography, also in Chemistry applied to other industries, are held in the evenings from 7.15 to 10, and are open to both sexes. Special attention is paid to Technical Laboratory work and the investigation of manufacturing difficulties. Session commences September 21.

EAST LONDON TECHNICAL COLLEGE, Mile End Road, E.—Chemistry: Professor, J. T. Hewitt, M.A., D.Sc., Ph.D.; Assistants, Clarence Smith, D.Sc., and F. G. Pope. Lectures and Practical Classes are conducted in the Day Technical College, the regular College Course being three years. The work of the first year corresponds with the requirements of the Int. Sci., Lond., of the next two years with the degree examination, B.Sc. (Honours and Pass). Special attention is given to work for the Honours Examination and research. Evening Classes

for London University Degrees are also held. The Day College opens on Sept. 19. Evening Classes begin Sept. 26.

UNIVERSITY TUTORIAL COLLEGE, 32, Red Lion Square, Holborn, W.C.—This Institution contains large Laboratories for Chemistry, Physics, Geology, and other subjects. Classes are specialised for Examinations of London University, but students may take up work for any Examination. The special feature of the College is that work goes on all the year round, thus affording students residing in the Country an opportunity of doing practical work during their Vacations.

IMPERIAL COLLEGE OF CHEMISTRY AND PHARMACY, 49 and 51, Imperial Buildings, Ludgate Circus.—Mr. F. Davis, B.Sc. An especial course of instruction is given at this College in Pharmacology and Therapeutics, *re* the Institute of Chemistry Examination. Students attending the College visit technical works.

CARPENTERS' COMPANY TECHNICAL INSTITUTE, Jupp Road, Stratford, E.—Principal, William Ping, F.C.S. Evening Classes in Theoretical and Practical Chemistry, and in many other Departments of Science and Art. Day Technical School. Session begins September 19.

SIR JOHN CASS TECHNICAL INSTITUTE, Jewry Street, Aldgate.—Principal, Charles A. Kohn, M.Sc., Ph.D., &c., assisted by R. S. Willows, D.Sc., and C. O. Bannister, A.R.S.M. Evening Classes in Chemistry, Metallurgy, Physics, and Mathematics, designed to meet the requirements of those engaged in Chemical, Metallurgical, and Electrical industries, and also in other departments of Science and Art. Practical laboratory work. Classes begin September 26. Full details may be obtained on application, or by letter to the Principal.

THE POLYTECHNIC, 309, Regent Street, W.—University of London Preparation Classes. Session begins Sept. 16.

THE INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—The Institute of Chemistry was founded in October, 1877, and incorporated by Royal Charter in June, 1885, (i.) to promote the better education of persons desirous of becoming public and technical analysts and chemical advisers on scientific subjects; (ii.) to examine Candidates, and to grant certificates of competency; and (iii.) to elevate the profession of Consulting and Analytical Chemistry by setting up a high standard of scientific and practical proficiency and by insisting on the observance of strict rules in regard to professional conduct. *The Studentship*.—Every Candidate for admission to the Studentship is required to produce evidence that he is at least seventeen years of age, and that he has passed a Preliminary Examination in subjects of general education, recognised by the Council of the Institute. He must also show that, at the time of making application for registration, he is working at a College or University approved by the Council, or in the laboratory of a Fellow of the Institute, with the object of adopting the profession of Analytical and Consulting Chemistry. *The Intermediate Examination*.—Candidates for admission to the Intermediate Examination are required to produce evidence (I.) of having passed an approved Preliminary Examination in subjects of general education; (II.) of having regularly attended systematic day courses, in a College or University recognised by the Council, during at least three academic years, in theoretical and practical Chemistry, and courses in Physics, Mathematics, and one of the following subjects, in accordance with the Regulations of the Institute: (i.) Advanced Mathematics; (ii.) Mechanics and Chemical Engineering; (iii.) Metallurgy; (iv.) Geology and Mineralogy; (v.) Physiology; (vi.) Bacteriology; and (II.) of having satisfactorily passed the Class Examinations in all the subjects required to be taken. As an alternative in the matter of training (II.), a candidate may take two years' training in a recognised Institution as indicated above, and work systematically for two other years in the laboratory of a Fellow of the Institute. A Candidate who has taken a Degree in Science (including

Inorganic and Organic Chemistry, and Physics in the Degree Examination, Mathematics having been also passed in at either the Final or Intermediate University Examination) in a University recognised by the Council, is eligible for admission to the Intermediate Examination of the Institute. Holders of certain Degrees or Diplomas are exempt from passing the Intermediate, and, by virtue of their qualifications, are eligible for admission to the Final Examination direct. *The Final Examination for the Associateship (A.I.C.)*.—Any Candidate who has passed the Intermediate Examination of the Institute, or who is entitled to claim exemption from passing the Intermediate Examination, is eligible for admission to the Final Examination. *Fellowship (F.I.C.)*.—For admission to the Fellowship, an Associate is required to have been registered for three years, and to have been continuously engaged during that period in the study and practical work of Applied Chemistry in a manner satisfactory to the Council. Full particulars are given in "The Book of Regulations for the Admission of Students, Associates, and Fellows," which may be obtained on application to Messrs. Blundell, Taylor, and Co., 173, Upper Thames Street, London, E.C. Price One Shilling.

BLACKBURN MUNICIPAL TECHNICAL SCHOOL.—Chemistry: Mr. Robert H. Pickard, D.Sc. (Lond.), &c., assisted by Mr. Jos. Yates and Mr. Allen Neville, B.Sc. (Lond.), F.I.C. Session opens Monday, September 12. Full details of the Classes are given in the "Students' Handbook," which may be had at the Institution (price 1d., by post 2½d.).

COUNTY TECHNICAL LABORATORIES, Chelmsford.—The new buildings are now open, and comprise facilities for practical instruction in Chemistry and Biology in their relation to Agriculture. Lecturer in Agricultural Chemistry, T. S. Dymond, F.I.C.; Assistants, G. Clarke, A.I.C., and others. Prospectus free on application.

REDRUTH SCHOOL OF MINES, CORNWALL.—Principal, Howard C. Ridding, A.R.S.M., F.I.C., assisted by a staff of Mining Engineers and Mine Surveyors. Courses of Practical and Theoretical instruction are given in Inorganic Chemistry, Assaying, Mineralogy, and Blowpipe Analysis, for intending Assayers and Mineral Chemists. Shorter Courses are also held in the above subjects to meet the requirements of intending Mining Engineers, and Prospectors. Practical instruction in Mining given at Pednandrea, the School Mine. Syllabus on application to the Registrar. Session commences Wednesday, September 7.

LEEDS INSTITUTE: TECHNICAL SCHOOL, Cookridge Street, Leeds.—Head Master, R. E. Barnett, B.Sc. (Lond.), A.R.C.S. Evening Classes are held in 41 subjects of Science and Technology, among which are:—Chemistry, Inorganic and Organic, Theoretical and Practical, by Mr. R. E. Barnett, B.Sc.; A.R.C.S.; Mr. J. B. Murray, Mr. A. McFarlane, and Mr. F. R. Penn; Metallurgy, Theoretical and Practical, and Iron and Steel Manufacture, by Mr. B. A. Burrell, F.I.C., F.C.S.; Magnetism and Electricity, and Practical Physics, by Mr. J. E. Tindall, B.A., B.Sc.; Botany, Lectures and Practical Work, by Mr. N. Walker; Photography, by Mr. S. E. Bottomley. Fees:—Lectures, from 5s. 6d. per Session; Laboratory work, from 5s. 6d. Systematic courses arranged for Pharmaceutical Students and for those engaged in Chemical Industries at composition fees. Session commences Sept. 19th. Prospectuses of various Classes free on application to the Secretary, Mr. Arthur Tait. Calendar of the Institute (218 pp.) post free 5d.

THE MUNICIPAL SCHOOL OF TECHNOLOGY, Sackville Street, Manchester.—This fine building occupies an area of upwards of 6800 square yards, and is six floors in height. Its equipment, which is nearly complete, is on a scale of great magnitude. It comprises laboratories and workshops for Mechanical, Electrical, and Hydraulic Engineering, for the Textile industries, for Photography, Collotype and Photo-mechanical processes, for the Letterpress and Lithographic industries, and for the industries included

within the scope of Architecture. The provision for the teaching of Chemistry, as might be expected in a district where the Chemical industries are important, is of an exceptionally complete character. It comprises, in addition to ample accommodation for pure Chemistry, laboratories for Metallurgy, Brewing, Bleaching, Dyeing and Printing, Paper-making, and Electro-chemistry. The Bleaching, Dyeing, Printing and Finishing, and the Paper-making industries are in addition extensively equipped in a separate building with machinery and appliances on an industrial scale. A Brew-house is also equipped on the low gravity principle, with a plant of four bushel capacity.

WOLVERHAMPTON MUNICIPAL SCIENCE AND TECHNICAL SCHOOL.—Inorganic and Organic Chemistry, Mr. W. Whitehouse, F.C.S.; Physics, Messrs. W. Whitehouse and A. T. Harrison, B.Sc.; Botany, Mr. Sidney Phillips, Ph.D. Day Classes in Chemistry and Physics, and Evening Classes in Chemistry, Physics, Botany, French, &c. Special arrangements are made for the requirements of Pharmaceutical and Medical Students. Session commences Monday, Sept. 12th. For other particulars and programme, apply Mr. G. F. Chell, Registrar.

The Chemical Laboratory at Wiesbaden.—During the Summer Term, 1904, the Chemical Laboratory Fresenius was attended by thirty-six Students. Of these twenty-nine were from Germany, two from England, and one from Austria, Luxemburg, France, Italy, and Russia. There were three Assistants in the Instruction Laboratory, and twenty-five in the Versuchsstationen (private laboratories). To the teaching staff of the Institution belong the Directors, Prof. Dr. H. Fresenius, Prof. Dr. W. Fresenius, Prof. Dr. E. Hintz, and also Prof. Dr. Med. G. Frank, Dr. L. Grünhut, Dr. E. F. Grosse, and Architect J. Huber. The next Winter Term begins on October 17. In the Summer Term, 1904, besides scientific work, there were many examinations carried on in the different departments of the Laboratory (Versuchsstationen) in the interests of trade, industry, mining, agriculture, hygiene, justice, and government.

EAST LONDON TECHNICAL COLLEGE, MILE END ROAD, E.

Session 1904-1905 commencing September 19 1904

DAY AND EVENING COURSES for the B.Sc. (Honours and Pass) Degree of the University of London are conducted by the following Lecturers, who are recognised teachers of the University of London:—

Mathematics	J. L. S. HATTON, M.A., and
Physics	W. F. S. CHURCHILL, M.A.
Chemistry	R. A. LEHFELDT, D.Sc., &c.
Botany	J. T. HEWITT, D.Sc., Ph.D., and
Engineering	C. SMITH, D.Sc.
Electrical Engineering	V. H. BLACKMAN, M.A.
	D. A. LOW, M.I.M.E.
	J. T. MORRIS.

The Day Courses in **ENGINEERING and CHEMISTRY** are also suitable for those entering manufacturing firms.
Calendar 2d. post free on application.

J. L. S. HATTON, Director of Studies.

THE MUNICIPAL SCHOOL OF TECHNOLOGY, SACKVILLE STREET, MANCHESTER.

THE ENTRANCE EXAMINATIONS for the Day Departments in—

MECHANICAL, ELECTRICAL, and SANITARY ENGINEERING.

The **CHEMICAL INDUSTRIES**, including BLEACHING, DYEING, PRINTING, PAPER-MAKING, BREWING, METALLURGY;

ARCHITECTURE and BUILDING CONSTRUCTION;

The **TEXTILE INDUSTRIES**;

PHOTOGRAPHY and PRINTING;

will be held on **MONDAY, TUESDAY, and WEDNESDAY, SEPTEMBER 12, 13, and 14, at 9.15 a.m.** Prospectus and entrance forms on application.

The **SCHOOL RE-OPENS on MONDAY, SEPTEMBER 19, at 9.15 a.m.**

J. H. REYNOLDS, Principal.

GRIFFIN'S METALLURGICAL BOOKS.

An Introduction to the Study of Metallurgy.

By SIR W. ROBERTS-AUSTEN. FIFTH EDITION. 18s.

The Metallurgy of Gold. By T. KIRKE ROSE. FOURTH EDITION. 21s.

The Metallurgy of Lead and Silver. By H. F. COLLINS. VOL. I.—LEAD. Price 16s. VOL. II.—SILVER. Price 16s.

The Metallurgy of Iron. By THOMAS TURNER. SECOND EDITION. 16s.

The Metallurgy of Steel. By F. W. HARBORD. With Section on Mill Practice, by J. W. HALL. 25s. net.

METALLURGICAL ANALYSIS and ASSAYING, for STUDENTS. By W. A. MACLEOD and C. WALKER. 12s. 6d. net.

ASSAYING. By J. J. BERINGER and C. BERINGER. NINTH EDITION. 10s. 6d.

ELECTRIC SMELTING and REFINING. By Dr. W. BORNHORS and W. G. McMILLAN. SECOND EDITION. 25s. net.

ELECTRO-METALLURGY. By W. G. McMILLAN. SECOND EDITION. 10s. 6d.

CYANIDING GOLD and SILVER ORES. By H. FORBES JULIAN and EDGAR SMART. 21s. net.

THE CYANIDE PROCESS of GOLD EXTRACTION. By JAMES PARK. THIRD ENGLISH EDITION. 7s. 6d.

ELEMENTARY METALLURGY. By A. HUMBOLDT SEXTON. THIRD EDITION. 6s.

LECTURES on IRON FOUNDING. By THOMAS TURNER. 3s. 6d. net.

GRIFFIN'S TECHNOLOGICAL BOOKS.

Gas Manufacture. By W. J. A. BUTTERFIELD. THIRD EDITION, thoroughly Revised. Vol. 1. 7s. 6d. net.

Acetylene. By F. H. LEEDS and W. J. A. BUTTERFIELD. 5s. net.

Oils, Fats, and Waxes. By C. R. ALDER WRIGHT and C. A. MITCHELL. SECOND EDITION. 25s. net.

Lubrication and Lubricants. By L. ARCHBUTT and R. M. DEERY. Illustrated. 21s.

The Chemistry of Indiarubber. By Dr. CARL O. WEBER. 16s. net.

Painters' Colours, Oils, and Varnish. By GEORGE H. HURST. THIRD EDITION, Revised. 12s. 6d.

Painters' Laboratory Guide. By G. H. HURST. 5s.

TRADES' WASTE: Its Treatment and Utilisation. By W. NAYLOR. 21s. net.

SEWAGE DISPOSAL WORKS. By W. SANTO CRIMP. SECOND EDITION. 30s.

WATER SUPPLY: Its Sources and Selection. By R. MIDDLETON. 8s. 6d. net.

SANITARY ENGINEERING. By FRANCIS WOOD. 8s. 6d. net.

ROAD MAKING and MAINTENANCE. By THOS. AITKEN. 21s.

GRIFFIN'S CHEMICAL BOOKS.

A Short Manual of Inorganic Chemistry. By A. DUPRÉ and WILSON HARR. THIRD EDITION. 6s. net.

Quantitative Analysis. By A. HUMBOLDT SEXTON. FOURTH EDITION. 3s.

Qualitative Analysis. By A. HUMBOLDT SEXTON. FOURTH EDITION. 3s. 6d.

Foods: Their Composition and Analysis. By A. and M. WYNTER BLYTH. FIFTH EDITION. 21s.

Poisons: Their Effects and Detection. By A. WYNTER BLYTH. THIRD EDITION. 21s.

Dairy Chemistry. By H. DROOP RICHMOND. 16s.

Milk: Its Production and Uses. By EDWARD F. WILLOUGHBY. 6s. net.

Flesh Foods. By C. A. MITCHELL. 10s. 6d.

FIRE and EXPLOSION RISKS. By Dr. VON SCHWARTZ. Translated by C. T. C. SALTER. 16s. net.

CHARLES GRIFFIN AND COMPANY, LTD.
Exeter Street, Strand, London.

THE SIR JOHN CASS TECHNICAL INSTITUTE. JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.

EVENING CLASSES IN CHEMISTRY, METALLURGY, PHYSICS, and MATHEMATICS.

Designed to meet the requirements of those engaged in CHEMICAL, METALLURGICAL, and ELECTRICAL INDUSTRIES, and in trades associated therewith.

Also preparation for the B.Sc. Examination of London University. Every facility for Special and Advanced Practical Work in well-equipped Laboratories, both in the Afternoon and Evening

CHEMISTRY { CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.
PHYSICS { R. S. WILLOWS, D.Sc., M.A.
METALLURGY { C. O. BANNISTER, Assoc. R.S.M.
MATHEMATICS { G. M. K. LEGGETT, B.A.

CLASSES IN METALLURGY.

GENERAL METALLURGY.
THE METALLURGY OF GOLD, SILVER, and LEAD.
FUEL and REFRACTORY MATERIALS.
METALLOGRAPHY, including PYROMETRIC WORK.
ASSAYING.

ANALYTICAL CHEMISTRY,

Including ELECTROLYTIC and GAS ANALYSIS.

Each Course of Lectures will be accompanied by suitable Laboratory Work.

GLASS BLOWING.

A series of Courses of Instruction will be given during the Session by Mr. A. C. COSSOR.

New SESSION begins MONDAY, SEPT. 26th.

The Institute is readily accessible, and near to Fenchurch Street, Liverpool Street, Broad Street, and Metropolitan Railway Stations. For details of the Classes apply at the Office of the Institute, or by letter to the PRINCIPAL.

W. H. DAVISON, M.A.,
Clerk to the Governing Body.

THE POLYTECHNIC, 309, REGENT STREET, W.

UNIVERSITY OF LONDON PREPARATION CLASSES.

Full Courses of Instruction for Matriculation, Inter. Arts, Science, and Engineering, and Final Arts. Special Courses for Final B.Sc. in Mathematics, Physics, and Chemistry.

Examinations are held at the above Institute.

NEXT TERM commences SEPTEMBER 16th, 1904.

Courses are so arranged that Students can do the work on Saturday and one evening per week.

Full particulars can be obtained on application to the DIRECTOR OF EDUCATION

CITY OF LONDON COLLEGE,

WHITE STREET and ROPEMAKER STREET,
MOORFIELDS, E.C.

MICHAELMAS TERM commences OCTOBER 3rd.

CLASSES and LABORATORY WORK in CHEMISTRY, PHYSICS, BIOLOGY, BOTANY, GEOLOGY, and PHYSIOLOGY. Special preparation for the Examinations of the Pharmaceutical Society, The Conjoint Board. Complete Courses for University Matriculation and Inter. and Final B.Sc., meeting during the Evening and on Saturdays.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

REDRUTH SCHOOL OF MINES, CORNWALL.

Session 1904-1905 begins September 7th.

A "Mining Certificate" is awarded to Students passing successfully through the School Course.

PRACTICAL MINING CLASSES, under the Instruction of Capt. WILLIAM HAMBLEY (late Government Inspector, South Africa). Distinctions in Mine Surveying in Open Examination five years in succession, including five Medals and Prizes, being all the awards of the City and Guilds of London Institute in 1904 in this subject.

SYLLABUS and every information on application to—

THE REGISTRAR.

RADIUM BROM.

POLONIUM.

RADIO-ACTIVE ORES.

BAR.-PLAT. CYAN. SCREENS.

" LARGE CRYSTALS.

ETC., ETC.,

ALL AT REASONABLE PRICES.

*Phone—4942 Gerard.

BIRKBECK COLLEGE,

Breams Buildings, Chancery Lane, E.C.

DAY and EVENING SCIENCE CLASSES—

CHEMISTRY J. E. MACKENZIE, Ph.D., D.Sc.
PHYSICS A. GRIFFITHS, D.Sc.
MATHEMATICS E. H. SMART, M.A.
BOTANY A. B. RENDLE, M.A., D.Sc.
ZOOLOGY H. W. UNTHANK, B.A., B.Sc.
GEOLOGY & MINERALOGY G. F. HARRIS, F.G.S.
METALLURGY, MINING, and ASSAYING .. G. PATCHIN, A.R.S.M.

Classes in FRENCH, GERMAN, SPANISH, RUSSIAN, ITALIAN, DUTCH.

Courses for University of London, Conjoint Board, Dental, and Pharmaceutical Examinations.

PRACTICAL WORK in highly equipped Laboratories.

CARPENTERS' COMPANY'S

TECHNICAL INSTITUTE, JUPP ROAD, STRATFORD, E.

CLASSES

IN

SCIENCE, ART, TECHNOLOGY, and LANGUAGES.

Chemical and Physical Laboratories.

Manual Training.

Workshops for PLUMBING, ENGINEERING, CARPENTRY and JOINERY, &c., WOOD-CARVING.

OPENS on MONDAY, SEPTEMBER 19th.

Prospectus on application.

THE CHEMICAL NEWS

VOL. XC., No. 2338.

A SUGGESTED EXPLANATION OF THE PHENOMENA OF OPALESCENCE OBSERVED IN THE NEIGHBOURHOOD OF CRITICAL STATES.*

By F. G. DONNAN.

It has been frequently observed (Guthrie, Rothmund, Friedländer, Konowalow) that a mixture of two liquids becomes opalescent before the temperature is reached at which definite separation into two phases occurs. Similarly a mixture of two partially miscible liquids remains opalescent at temperatures beyond that corresponding to the disappearance of the meniscus. Apparently analogous phenomena have been noticed in the case of one-component liquid-vapour systems, especially by Wesendonck and Teichner. The latter has observed the existence of permanent opalescent states in the case of carbon tetrachloride at temperatures several degrees higher than the critical. These phenomena, so far as they refer to mixtures of liquids, have been studied by Konowalow, who considers that they are due to a partial separation into two phases, occurring round dust-nuclei acting as centres of disturbance. Konowalow shows that such a disturbance of equilibrium in the otherwise homogeneous liquid will, in the neighbourhood of the critical solution temperature, involve only a slight expenditure of work owing to the small change of vapour-pressure with composition under these conditions.

The author suggests another explanation which involves the following suppositions:—

(a) Below the critical temperature the interfacial tension between the two phases is positive for all values of the radius of curvature.

(b) At the critical temperature the interfacial tension becomes zero for all ordinary curvatures, but remains positive for very small values of the radius of curvature. It will be seen that this assumption involves the further one, that at the temperature of disappearance of the meniscus at a bounding surface of ordinary curvature (critical temperature) the two phases do not become identical.

(c) At temperatures slightly above the critical the interfacial tension is still positive for very small radii of curvature, but negative for all ordinary curvatures.

(d) At still higher temperatures the interfacial tension becomes negative for all curvatures.

These assumptions carry with them the main assumption that the interfacial tension between two liquid phases increases in general with diminution of the radius of curvature of the bounding surface. This increase, however, need not extend to the very smallest values of the radius of curvature. It is also necessary to suppose that the curve connecting interfacial tension with radius of curvature of the bounding interface suffers a shift towards the region of negative values of the interfacial tension as the temperature rises.

Granting these assumptions, the existence of permanent opalescent states above the ordinary critical-point follows at once. For it can be shown that the conditions specified, for example, under (c) would produce a system in which one phase would be distributed throughout the other in a state of very fine sub-division. If the particles are small enough such a system would not present a milky appearance, but would doubtless be opalescent.

An interesting question concerning the nature of the critical state is thus raised, namely, as to whether there is not sufficient experimental evidence to justify the belief that the passage of systems through critical states is in-

adequately described by the simple theory of Andrews? That is the wider question at issue. The particular form of explanation suggested in the present paper also raises the question as to whether the observed phenomena may not admit of interpretation by taking into consideration the operation of capillary forces?

These points seem worthy of discussion, especially in relation to the theories of "gaseous" and "liquid" molecules, "Gasonen" and "Fluidonen" devised in recent years by de Heen, Traube, and others.

The present communication has arisen out of a correspondence on the subject with Professor van't Hoff, to whom the main idea is due.

ON THE ENERGY OF WATER AND STEAM AT HIGH TEMPERATURES.*

By Professor C. DIETERICI.

THE author has devised a method for determining the specific heat of water at temperatures up to 300° C. The water is inclosed in quartz tubes, which are sufficiently strong to withstand the pressure of steam—namely, about 100 atmospheres at 300° C.—and the determinations are made with the aid of the ice calorimeter. The results obtained may be expressed by the formula—

$$c_1 = 1.0160 - 0.006057 t + 0.004302 t^2;$$

in which the specific heat, c_1 , is given as a function of the temperature. The formula holds between 50° and 300° C., but does not hold below 50° C., because at such low temperatures the point of maximum specific heat first observed by Rowland occurs.

The observations made with water completely enclosed in a tube give the difference between the energy of the liquid water at t° C. and that of the water at 0° C. Since the heat of evaporation is known or calculable, this quantity, diminished by the external work, gives the energy difference between saturated steam and liquid water at t° C.

Very careful observations have been published by Sir W. Ramsay and S. Young (*Phil. Trans.*, 1891) on the pressure of unsaturated steam between 140° and 270°; and since the relation between energy change and volume at constant temperature is given by the equation—

$$\left(\frac{\partial U}{\partial v}\right)_T = T \left(\frac{\partial p}{\partial T}\right)_v - p,$$

of the mechanical theory of heat, the change of energy of superheated steam depends only on the pressure, and can be calculated from the author's present observations. It is therefore possible to calculate the energy isothermals and to draw the isothermal lines for water.

After applying the most accurate methods of calculation possible to the new observations, the author draws the following conclusions:—

At about 200° C. the specific heat of superheated steam at constant volume is 0.5° , and is practically independent of the volume if the latter is much greater than the saturation volume. As, however, the volume diminishes to the volume of saturation, the specific heat increases to about 0.7° . The specific heat at constant pressure, C_p , similarly varies from 0.6 to 0.8 . Further, in the well-known equation of state of van der Waals,—

$$p + \pi = \frac{RT}{v - b},$$

the cohesion pressure, π , cannot be taken as $\frac{a}{v^2}$, but is such a function of v and T that it has a considerable value for large volumes at low temperatures, and for small volumes at high temperatures.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

ON DOUBLE ACETYLIDES.*

PART I.

By Major A. E. EDWARDS and Prof. W. R. HODGKINSON.

The authors have investigated the action of acetylene on a number of salts with a view to obtaining an explosive of a sufficiently safe nature to be used for military purposes, and refer in the present paper to some silver compounds which they have obtained. The acetylene employed was purified as well as possible from sulphur and phosphorus compounds, and was then brought in contact with silver salts in solution or suspended in boiling water. In some cases the gas was passed for some days continuously through the water containing the suspended salts.

A number of organic salts, such as silver acetate, benzoate, and butyrate, yield the same acetylide as that obtained from neutral or faintly alkaline silver nitrate solution. A solution of silver nitrate in nitric acid of 1·3 sp. gr. did not give this particular acetylide, but one containing nitric acid as nitrate. Solutions of silver salts in potassium cyanide or in thiosulphate are quite unaffected by acetylene, but pure thiocyanate suspended in water is acted upon; the product in this case is explosive, and contains both sulphur and cyanogen, but was not obtained in a pure state.

The following compounds have been obtained in a definite form, analysed and examined as to their sensitiveness to percussion and heat.

From a boiling solution of silver bichromate acetylene precipitates an orange-red salt of the composition $(Ag_2O \cdot 2H_2O \cdot Ag_2CrO_4)$, whilst chromic acid is liberated. When dry this substance is very sensitive to friction, and explodes violently at 157° C. Corresponding compounds are formed from silver sulphate, selenate, tungstate, and molybdate; they are all much less sensitive than the chromic acid compound, and explode much more feebly.

Compounds from the phosphate and vanadate were obtained with difficulty, and no satisfactory analyses were made; they explode in a very feeble but peculiar manner.

ON THE CHARACTERISTIC SULPHUR LINES
IN THE PHOTOGRAPHIC SPECTROSCOPY
OF MINERALS.*

By M. le Comte A. DE GRAMONT, D.Sc.

In previous papers† I have given the descriptions and measurements that have been obtained by direct observation in the visible portion of the spectrum of the electric spark striking between two fragments of minerals connected respectively to the two poles of an induction coil through a condenser. Under these conditions the spark shows, not only the metallic lines, but also those of the *metalloids* which are present in combination in the mineral. Fused salts have also given me the same results, which may be summed up as follows:—

The condensed spark, striking on the surface of a compound, dissociates it, giving a very bright line spectrum, in which each substance—metal or metalloid—is represented by the characteristic lines of its own spectrum. Thus we have a decomposition spectrum, or true "spectrum of dissociation," which may be looked upon simply as formed by the superposition of the spectra of the elements present in the compound.

I have followed up this examination with photographic methods. The results obtained now only apply to a portion of the visible lines; that is to say, from a small part of

the green to the extreme violet, and thence to the whole of the ultra-violet. The characteristic lines of the elements are thus no longer the same, at least to a great extent, and I propose here to describe those of sulphur.

I have made use of coils the powers of which varied from 3 c.m. sparks up to sparks of 20 c.m. in length, and of condensers consisting of Leyden jars each having 12 square decimetres of surface, which corresponds to a capacity of 0·043 microfarad; I used as many as six jars with the large coil. A variable spark gap was introduced into the secondary circuit, so as to regulate the frequency and the potential of the spark without altering the distance apart of the fragments of mineral, which were kept at about 1 m.m. at the most, fixed in platinum forceps similar to those used with the blowpipe. It was also possible to introduce into the same circuit self-inductors of different sizes; these have enabled me to eliminate the air spectrum (with two jars and a self inductor of 0·00008) without diminishing the intensity of the sulphur lines to any great extent, which disappear, however, with a self-inductor of slightly larger size. After having suppressed the air spectrum, we are able to reinforce that of the sulphur by increasing the condensation by adding another jar (*Comptes Rendus*, May 5, 1902).

The most easily recognisable sulphur lines are in the green:— α (5665 to 5599), β (5473 to 5429), γ (5243 to 5320), δ (5213 to 5201). These are the most sensitive for chemical research, but it has been found also that the portion of the spectrum which acts on ordinary photographic plates—the most characteristic sulphur lines for photographic purposes—is the following, all the lines being of considerable intensity:—

$S\eta$	4812·0	
$S\theta$	4716·4	
	4552·6	
$S\mu$	4525·1	
	4483·6

		3919·5
		3495·4

Double.

This spectrum was obtained with a spark between two fragments of galena (PbS) and argyrose (Ag_2S). Above the spectrum of the mineral was placed, on the same plate, the spectrum of sulphur obtained from a Plücker tube heated and filled with the vapour of this metalloid, and of which the lines are extended into the two spectra. The spectrograph consisted of two prisms of heavy flint glass and an achromatic objective of 33 c.m. focal distance. The wave-lengths of the sulphur lines given here are taken from the paper by MM. Eder and Valenta ("Die Spectren des Schwefels," *Denkschriften des Kais. Akad. d. Wissenschaften*, lxvii., Wien, 1898) obtained with a scale; my measurements, compared with the lead and silver lines, agreed with those of MM. Eder and Valenta, to about two units in the fifth figure.

On the other hand, the relative intensities of the ultra-violet lines were different from those observed by these authors, and I feel compelled to give here three principal lines I found in this part of the spectrum, which I examined with a spectrograph with quartz prism and lenses. Further, the important lines, from the analytical point of view, are those of the group $S\mu$, $S\pi$, and especially $S\rho$; they can be obtained, as is seen, with flint prisms, which makes their detection more simple for chemists, and enables a greater dispersion to be reached, thereby separating the different groups of lines.

I propose to continue the study of the sulphur lines in the most refrangible portion of the ultra-violet spectra, using the fused alkaline sulphates.

NEW LOW TEMPERATURE PHENOMENA AND THEIR SCIENTIFIC APPLICATIONS.*

By Sir JAMES DEWAR, M.A., D.Sc., LL.D., F.R.S.

THE matter the author was about to bring before the Section, speaking generally, was not exactly new as it related to the absorption of gases by charcoal. It was found by Saussure about the beginning of last century that gases were absorbed by charcoal to a variable extent, and, moreover, that some kinds of charcoal were more active than others. Coconut charcoal, Hunter discovered about 1865, possessed twice the condensing power of any previously prepared charcoal. Very little, however, had been done in this field of investigation for years, but with the advent of Crookes's radiometer and Sprengel's vacuum pump the application of charcoal for removing gases from the residual vacuum was tried by Tait and the author about 1875. It was easy to solidify all traces of condensable gases, such as carbonic anhydride, sulphur dioxide, &c., out of any vessel by the use of liquid air, and even the less condensable gases could be removed from any space by a similar application of liquid hydrogen.

Wishing to investigate thermal interactions at low temperatures the author had made an attempt to induce palladium and hydrogen to combine under such conditions, but the result was a failure. He then resorted to the use of coconut charcoal, and the results obtained the author had recently described in two papers communicated to the Royal Society, respectively entitled "The Absorption and Thermal Evolution of Gases Occluded in Charcoal at Low Temperatures" and "The Separation of the Most Volatile Gases from Air without Liquefaction" (see CHEM. NEWS, vol. xc., pp. 73 and 90). Demonstrating the absorptive properties of this substance, he first showed that some charcoal contained in a tube when immersed in liquid air absorbed air with great avidity; if the supply was cut off a very high vacuum at once ensued.

In another experiment air at atmospheric pressure in a Crookes's radiometer was placed in connection with a tube containing charcoal. The radiometer vanes remained absolutely still when placed in the beam of light from the electric lamp, but shortly after the charcoal was immersed in liquid air the vanes began to move, and soon attained a great velocity, indicating a very high vacuum. When the liquid air was removed, the radiometer soon slackened, and gradually but rapidly came to rest again, showing that the air resistance had been restored in the radiometer, and that the gas absorbed by charcoal at a low temperature was given off again when the temperature was raised. When a current of air was passed over charcoal saturated with air at $-185^{\circ}\text{C}.$, the escaping gas was at first all nitrogen, and in a quarter of an hour the gas held by the charcoal contained as much as 58 per cent of oxygen, instead of the usual 21 per cent. By simply raising the temperature this 60 per cent air could be collected, but if the air was taken off in two successive portions the percentage of oxygen rose to nearly 80 per cent in the last half. All gases were absorbed in larger quantities at $-185^{\circ}\text{C}.$ than at $0^{\circ}\text{C}.$; helium was absorbed in smallest quantity, and then followed neon, hydrogen, nitrogen, argon, carbonic oxide, and oxygen, but with gaseous mixtures the absorption was still greater.

The lecturer then showed by a series of beautiful vacuum tube experiments the behaviour of nitrogen, oxygen, hydrogen, and argon when submitted in contact with charcoal to the cooling influence of liquid air. A nitrogen tube, for instance, exhibited the usual violet colour when the spark passed through it, but as soon as the charcoal was immersed in the liquid air the tube passed through various stages of attenuated brilliancy until ultimately the vacuum became so high that the current could scarcely overcome the resistance. When the liquid air was removed

the changes were passed through in the reverse order. Oxygen passed through a similar series of changes, but in the case of hydrogen the absorptive power of the charcoal at the temperature of liquid air was not great enough to render the tube non-conductive. In the case of argon the light due to that element rapidly disappeared with the cooling of the charcoal, but a brilliancy remained due to a considerable residue of helium and neon, which was not absorbed. Nitrogen from air did not exhibit this character to the same extent, because the quantity of helium and neon was 100 times less than in the argon. It is possible by means of charcoal absorption and by the use of different condensation temperatures to separate gases from mixtures and to examine various gases spectroscopically. For instance, in the unabsorbed residue from 200 c.c. of air, neon and helium can be detected by the spectroscope after the nitrogen and oxygen are absorbed, and the brilliant ruddy glow of the neon discharge is most brilliant in the residue from three litres of air. By boiling out 300 c.c. of gas from sea-water, rain-water, Cambridge water, and London water, and subjecting it to fractionation by means of charcoal absorption at low temperature, helium and neon had been detected in all cases, showing that these elements were more extensively disseminated than was previously supposed.

Finally, the author said that hydrogen could be completely absorbed by charcoal at the boiling-point of hydrogen, and that helium at the temperature of solid hydrogen, 15° absolute, was similarly condensed. It resulted from these experiments that the helium boiling-point would be about 5° or 6° absolute, so that Lord Kelvin's predicted 5° absolute might yet be obtained.

THE RELATION BETWEEN THE CRYSTALLINE AND THE AMORPHOUS STATES AS DISCLOSED BY THE SURFACE FLOW OF SOLIDS.*

By G. T. BEILBY.

IN former papers the phenomena observed in connection with the flow of solids have been fully described, and in the most recent of these the results of the observations have been applied to the study of the hard and soft states in metals. The purpose of the present paper is to direct attention to the very general character of the relations which have been found to exist between the amorphous and the crystalline states.

Observations on flow in crystalline substances are described and illustrated by photo-micrographs. By the use of etching in stages the successive layers of a polished or disturbed surface are disclosed, from the smooth vitreous surface, through a granular layer to the undisturbed crystalline body beneath. The demonstration that the polish of a lens of rock crystal has resulted from the formation of a flowed layer of amorphous phase on its surface suggests that no crystalline substance is too hard to yield to the mechanical flowing action.

The passage of the amorphous back to the crystalline state by the agency of heat is discussed, and attention is directed to the important bearing of the fact that this transformation occurs at a definite temperature, on the behaviour of solids at ordinary atmospheric temperatures. It is suggested that as the stability-point of ice is probably a long way below the freezing-point, the amorphous phase can only have a transient existence at ordinary atmospheric temperatures; while at the lower range of winter temperatures within the Arctic Circle, the amorphous phase, once formed, may be stable and permanent.

The grinding of crystalline substances to powder does not simply consist in their reduction to finer and finer

* Abstract of a Lecture delivered before the British Association (Section B), Cambridge Meeting, 1904.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

crystalline fragments, but it involves the transformation of at any rate a part of the substance into the amorphous condition.

When crystalline powders are formed into cakes by pressure the cementing material is the amorphous phase which results from flow.

In metals, and probably in most other solids, the physical and other properties of the two phases are so distinct that it is not difficult to determine the transition temperature or stability-point in the transformation $A \rightarrow C$.

From the existence of a definite stability-point it is argued that not only must all crystalline substances be capable of existing in the amorphous as well as in the crystalline state, but that, by purely mechanical means, it is possible to transform them into this state.

These observations, and the conclusions to which they have led, have a very direct bearing on the flow of rocks. The recognition of the transformation from crystalline to amorphous through an intermediate mobile phase, for the first time supplies an explanation of why flow which has been started by stresses can cease while the disturbing stresses are still maintained.

ON SOME REACTIONS BETWEEN AMMONIUM SALTS AND METALS.*

By W. R. HODKINSON and ARTHUR H. COOTE.

As far back as 1879, a note was published by one of us on the action of aluminium on ammonium chloride, and we have recently continued the investigations of the behaviour of ammonium salts generally towards metals.

Ammonium nitrate, either in aqueous solution or in a fused state, acts very vigorously on some metals.

There is a notable difference, as a rule, between the fused salt and its aqueous solution in regard to rate of action on the more common metals; but in the case of the metal cadmium there is little difference perceptible between the rate of action of an aqueous solution and the melted salt. Cadmium placed in an ice-cold saturated solution of ammonium nitrate rapidly dissolves without evolution of gas. The liquid becomes alkaline from presence of a little free ammonia; the solution gives off nitrogen only when heated to 100° , when the cadmium ceases to dissolve and some remains in excess. The solution contains a little free ammonia, and apparently the nitrite of cadmium and ammonium. This is, at any rate, indicated by the fact that every trace of cadmium can be precipitated from this solution by passing through it a stream of carbon dioxide at the ordinary temperature. The solution contains mainly ammonium nitrite.

Zinc and magnesium act in a similar manner, but, owing to the formation of somewhat insoluble double ammonium compounds, not to the same extent or with the rapidity observed with cadmium. Aluminium, iron, mercury, and silver are unaffected by an aqueous solution of the salt, but nickel, copper, and lead are slightly active. Lead becomes coated with a somewhat insoluble nitrite.

Melted ammonium nitrite has no action on iron, mercury, or aluminium, and, in fact, these metals are quite unaffected when the salt is heated with them so strongly as to decompose with formation of red fumes; under these conditions silver is slightly attacked. Approximately it may be stated that when the salt is just fused the following metals are acted upon at rates about in the order given:—Cadmium, magnesium, zinc, copper, nickel, lead, bismuth.

The mechanism of the reaction as regards cadmium and fused ammonium nitrate seems to be that first a little ammonia is split off, and then a metallic nitrate formed. This, however, involves the expulsion of hydrogen, which in turn reduces the nitrate of the metal to nitrite, which

immediately reacts with the ammonium salt in the usual manner, liberating nitrogen.

Weighed quantities of metals have been allowed to act upon ammonium nitrate in a vacuum-tube maintained at the melting-point of the salt. In the cases of cadmium and copper the gas collected was pure nitrogen; with cadmium the amount of nitrogen collected falls a little short of 4 atoms of nitrogen to 1 atom of metal; with copper it is nearly 3 atoms of nitrogen to 2 atoms of the metal. The amount of ammonia liberated in the first phase of the reaction may have something to do with this deficit of nitrogen, but we are unable to explain it fully at present.

Powdered cadmium dissolves in a solution of aniline nitrate, and if the temperature be maintained below 10° no appreciable evolution of gas occurs, and a considerable yield of diazoaminobenzene is obtained. The course of the reaction is very similar to that with the ammonium salt, a little aniline being liberated in the first instance.

ON CRYSTAL STRUCTURE AND ITS RELATION TO CHEMICAL CONSTITUTION.*

By Prof. PAUL GROTH.

THE molecular hypothesis assumes that in solid bodies the molecular movements occur about certain equilibrium positions which can only be altered by the operation of external forces. In crystalline bodies the spacial arrangement of these equilibrium positions must consequently be a regular one.

The possible kinds of crystal structure—that is, the kinds of regular arrangement of congruent molecules—were first discussed by Bravais, who described fourteen such kinds of structure, and distinguished them as "space lattices." Bravais's theory, however, only explains seven kinds of symmetry which possess the properties of crystal symmetry, and the incompleteness of his work reposes on the introduction of an unnecessary assumption, namely, that the molecules occupy parallel positions. Sohncke discarded this assumption in attacking the problem, and merely sought for those arrangements of congruent molecules in which the arrangement of parts is the same about every molecule; he thus arrived at sixty-five regular "point systems." By the discovery of these most, though not quite all, of the symmetrical relationships of the properties of crystals became explicable. Sohncke further developed his theory of crystal structure by introducing the assumption that two or more regular point systems, consisting of different kinds of molecules, may be interlaced or supposed to interpenetrate in such a way that equilibrium results. This, however, is only possible when the different point systems possess the same "coincidence movements" (*Deckschiebungen*)—that is to say, when they are built up from space lattices of identical dimensions. This form of the theory is also deducible from the theory of regular point systems if the different individual atoms constituting the molecule are considered in place of the centres of gravity of the molecules; each set of analogous atoms then form a regular point system, and, by the interlacing of the several systems, a compound system is obtained consisting of as many component systems as there are atoms in the chemical molecule. This, the most general theory of crystal structure, may be summarised by the following definition:—

A crystal—considered as indefinitely extended—consists of n interpenetrating regular point systems, each of which is formed from similar atoms; each of these point systems is built up from n interpenetrating space lattices, each of the latter being formed from similar atoms occupying parallel positions. All the space lattices of the combined

* Read before the British Association (Section B), Cambridge Meeting, 1904.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

system are geometrically identical or are characterised by the same elementary parallelepipedon.

In this form the theory is capable of elucidating all the observed regularities of crystal structure, and it is unnecessary to assume the operation of any "molecular forces" in addition to the forces which act upon the atoms themselves. No difficulties now arise in ascribing to the atoms the power of assuming a definite orientation, since, according to J. J. Thomson, the atoms are not mere points, but highly complex structures.

If a crystal is built up from but one kind of atom it consists of a crystalline element, and is produced from but one kind of regular point system the properties of which depend upon the forces exercised upon each other by the similar atoms involved. In the case of a chemical compound, however, there must be just as many regular point systems in the combined system as there are atoms in the chemical molecule, and the arrangement of the combined system must correspond with the equilibrium of the forces with which similar and dissimilar atoms act upon each other.

On solution, melting, or evaporation of the crystal the combined system separates into its component and freely moving molecules, and the relative positions in space of the point systems or space lattices, composed from the several kinds of atoms, must therefore be such as to correspond with the arrangement of the atoms in the chemical molecule. The difference between the crystalline and the amorphous state thus consists in that in the latter the chemical molecules have a mutually independent existence, whilst in the crystal the idea attached to the term molecule is different, the molecule being regarded only as a group or assemblage of atoms belonging to several interpenetrating point systems. Such an assemblage can under certain conditions be quite an arbitrary one; thus, the structure of crystalline sodium chloride—making the simplest conceivable assumption—consists of a cubic space lattice of sodium atoms, and a similar space lattice of chlorine atoms, the latter atoms occupying the mean points in the lattice of sodium atoms. It is obviously a matter of quite arbitrary choice with which of the neighbouring sodium atoms a particular chlorine atom will remain combined as a molecule of sodium chloride when the molecules of the latter separate during the passage into the amorphous state by melting, solution, &c. The same considerations naturally hold when, instead of two simple space lattices, two regular point systems consisting of chlorine and sodium atoms are imagined to coalesce. In this case any multiple of the complex NaCl may be regarded as the "molecule," and thus has arisen the failure of all attempts hitherto made to determine the molecular magnitudes of crystalline bodies.

In order to ascertain the crystal structure of a substance with any degree of probability the most complete possible knowledge is required concerning it, such as of its optical properties, its cohesion relationships, the orientation of its different solubility directions (etch figures), and more especially the knowledge of its crystalline form under the most widely differing conditions of formation. If the product of only one crystallisation is examined, the possibility is incurred that the crystals so produced exhibit casual forms developed under quite special conditions of growth; and only by investigating many different crystallisations separated from different solvents under different conditions of temperature, &c., does it become possible to recognise those faces the development of which is most favoured during growth, or, what is the same thing, to learn what planes are parallel to the greatest density of structure. If these planes are taken as the elementary faces, it is always found, not only that they are identical with the cleavage planes, with the most stable planes of twinning, &c., but also that the other forms present on the crystal assume the simplest indices. The greater the number of forms observed upon the crystals so much the greater is the probability of being able to choose the correct elements for the crystal, because the faces most likely to be favoured during the growth of the crystal are those the indices of which are

composed of the simplest numbers. Having found the correct elements of the crystal, it is a simple matter of calculation to ascertain the ratio of the three parameters and the angles of the elementary parallelepipedon upon which the structure of the crystal is built up, and which is therefore a prime characteristic of the structure.

Since the equilibrium in a crystal structure is dependent on the conditions of movement of the component atoms, the stability of the equilibrium must alter with the temperature; and since each form of structure may possess several stable equilibrium positions of different degrees of stability, it follows that a particular crystal structure will assume the most stable of the possible kinds of equilibrium only within a certain range of temperature, constant pressure being assumed. Outside these limits other kinds of arrangement will be in more stable equilibrium, and on exceeding the limits a discontinuous change of all the physical properties of the body will occur; that is to say, a change into another modification of different crystal structure will ensue. Polymorphism, the property of existing in different crystalline phases, must be distinguished from polysymmetry, or the power possessed by pseudo-symmetrical crystals of forming apparently simple crystals of higher symmetry by repeated twinning. Amongst the latter the change into the form of true higher symmetry can indeed take place at a specific temperature, but the change is not accompanied by a discontinuous change in the density and the specific heat. Amongst the truly polymorphous bodies, however, even when the crystalline forms of the several modifications exhibit a certain similarity, so great a dissimilarity still exists between them in physical and crystallographical respects that the various modifications must be referred to quite different elementary parallelepipedons. A difference in the crystal structure is thus introduced, and this may arise from the regular point systems, which compose the combined system, consisting each of one or of several space lattices.

On comparing the polymorphous relationships of two different but chemically similar substances it is found that the temperature (or pressure) limits of the stability of the several modifications are not the same—thus, considering analogous, chloro-, bromo-, and iodo-compounds, it is often observed that the temperatures of change for the chloro- and bromo-compounds are lower than for the iodo-compound, just as is often the case with the melting-points of such analogous substances. As a result totally different polymorphous modifications of the various members of analogous series exist at one and the same temperature.

The foregoing leads to the definite conclusion that the relationships between the crystal structures of two chemically related substances can only be recognised if their corresponding modifications are available for comparison; every chemico-crystallographical comparison of two or more substances must therefore be based upon a study of the polymorphism relationships. If the existence of corresponding modifications is established by such a study, the further complete investigation of these forms leads to the determination of the most probable values of the dimensions of the elementary parallelepipedon of the crystal structure; by taking the planes of the elementary parallelepipedon as the basis for assigning symbols to the crystal faces, the so-called "elements" of the crystal give immediately the angles, α , β , and γ , and the relative lengths $a:b:c$ of the sides of the elementary parallelepipedon. The elements of the two comparable substances being—

1. $a_1 : b_1 : c_1$ and $\alpha_1, \beta_1, \gamma_1$
2. $a_2 : b_2 : c_2$ and $\alpha_2, \beta_2, \gamma_2$

the comparison of the two sets of elements, if all the other necessary conditions are fulfilled, permits the determination of the alteration which ensues in the structure of the crystal 1, if it be converted by substitution into the substance of crystal form 2. This alteration may be regarded as a "homogeneous deformation," because a homogeneous edifice—the crystal structure of the first substance becomes thereby converted into another homogeneous edifice—the

crystal structure of the second substance. The character of this deformation cannot be recognised through the comparison of the axial ratios of the two substances if these are stated in the ordinary way, but can only be ascertained if the axial ratios are expressed in terms of the same unit. For this purpose an exact determination of the specific gravity of the two substances is made and the "equivalent volume" calculated therefrom; the dimensions (parameters) of the elementary parallelepiped can then be at once referred to the same unit, namely, to the side of a cubic elementary parallelepipedon of a substance of which the molecular weight is equal to the density (equivalent volume = 1). Such comparable parameters are termed the "topical axial ratios," and are described as χ , ψ , and ω . The comparison of the following substances may be quoted as a simple example:—

Ammonium iodide crystallises in hexahedra and exhibits a perfect cleavage parallel to {100}, so that its crystal structure is undoubtedly hexahedral or cubic. Tetramethylammonium iodide crystallises in the tetragonal system, and shows perfect cleavages parallel to {100} and {001}; its most probable crystal structure therefore differs from that of ammonium iodide only in the ratio of the axes a and c . The direction in which the crystal structure has been altered by the substitution of $4H$ by $4CH_3$ is seen by a comparison of the topical axial ratios; as the following table shows, the principal axes c has undergone no noteworthy change, but the parameter of the two axes a and b is much greater in the methylated compound. Tetraethylammonium iodide is similarly tetragonal, and exhibits a regular increase of the parameter of the two equal axes in the same direction; the increase in the equivalent volume is also quite regular during the transition from $4H$ to $4CH_3$ to $4C_2H_5$. On further attempting to lengthen the dimension, a and b , by exchanging $4C_2H_5$ for $4C_3H_7$, a quite different deformation comes into play. As a result of this ψ increases, and χ and ω decrease.

	NH_4I	$N(C_2H_5)_4I$	$N(C_3H_7)_4I$	$N(C_4H_9)_4I$
Equivalent volume	57.51	108.70	162.91	235.95
$\chi =$	3.860	5.319	6.048	6.093
$\psi =$	3.860	5.319	6.048	7.851
$\omega =$	3.860	3.842	3.686	4.933

The so-called morphotropic relationships between numerous organic substances which have been brought to light during many years past consist mainly in the observation that the substitution of H by CH_3 , NO_2 , OH , &c., gives rise in many cases to but partial changes in the crystalline form. In order, however, to determine the direction of deformation, as has been done above for the alkylated ammonium iodides, all the substances must be studied in accordance with the principles laid down above, and their specific gravities determined; further, in cases in which no morphotropic relationships can be traced it must be ascertained whether the substances compared are not different—non-corresponding—modifications. Regularities from which conclusions can be drawn concerning the position of the atoms or atomic groups in the crystal structure can only be traced as a result of this kind of complete investigation of long series of chemically related compounds. That such conclusions can be drawn is evident from the above example.

The only study of related substances which satisfies all the requirements noted above is to be found in the brilliant work of Tutton on the sulphates and selenates; this relates to the comparatively small changes which result from the replacement of K by Cs , Rb , and NH_4 in so-called "isomorphous compounds." In spite of the smallness of the changes produced, Tutton has been able to establish definite relationships between the atomic weight of the metal concerned and the crystal structure, and his work therefore stands as a sample of the way in which chemo-crystallographical investigations must in the future be carried out for the purpose of determining the mutual relationship of the crystal structure and the chemical substance.

As is well known, isomorphous substances possess the power of forming homogeneous mixtures, and, since in these mixtures the properties continuously change with the composition, they have been described as "solid solutions." Such a miscibility often exists, however, within certain limits between substances possessing totally different crystal structures, so that the solidification curves of the molten mixtures of such substances show just the same relationships as if the mixtures had been made from two truly isomorphous materials. It is therefore incorrect to conclude that two substances are isomorphous from an examination of the melting and solidification curves of their mixtures.

Only those substances which exhibit corresponding crystal structures as a result of their chemical analogy can be regarded as isomorphous; mixed solutions of two such substances may be caused to deposit apparently homogeneous crystals in which the atoms of one element are partially replaced by atoms of another without overthrowing the equilibrium of the crystalline structure. The preservation of the equilibrium will clearly be the more easy the less the differences between the forces determining the crystal structure in the two isomorphous substances, and the less therefore also the difference between the two crystal structures. The proportions of the mixture must be immediately deducible additively from those of the components; thus, for instance, each component must preserve its individual specific gravity in the mixture, as has been shown by the careful investigations of Retgers to be the case.

Lastly, the facts which Kipping and Pope have brought to light in connection with optically active and racemic compounds can be brought into unison with the above discussion on crystal structure. Racemic compounds behave towards the optical antipodes like molecular compounds of the same, the crystalline structure being a combined system of the two enantiomorphous systems, whilst the pseudo-racemic substances stand to the active components in the same relation as polysymmetric substances.

The object of the present paper is to state clearly the point of view in accordance with which previous investigations must be developed in order that generally applicable conclusions can be deduced therefrom.

THE CONSTITUTION OF NICKEL CARBONYL.*

By H. O. JONES, M.D., D.Sc.

THE study of the chemical reaction of nickel carbonyl, first undertaken in association with Professor Sir J. Dewar, has been continued and extended.

Nickel carbonyl reacts readily with hydroxylamine in alcohol solution to give a bluish violet-coloured gum which solidifies on standing in a desiccator, is insoluble to all solvents, and is decomposed by water and acids and on heating to $100^\circ C$. The action of water and of heat on the compound gives rise to new compounds similar in appearance to the original substance, and which react with acids, giving nickel and hydroxylamine salts and carbon dioxide.

These compounds have not been obtained pure enough to give analytical results of any value, but the ratio $Ni : NH_2OH$ in the original compound is found to be $1 : 4.5$, and is probably $1 : 4$.

Hydrazine hydrate reacts in a similar way, and gives a blue-violet solid compound.

The formation of these substances shows that nickel carbonyl can react as a ketonic compound.

Nickel carbonyl reacts with the alkyl magnesium iodide compounds of Grignard, in some cases violently, to produce dark coloured oily and solid substances, which contain nickel, magnesium, and iodine, and are decomposed by acids, yielding a mixture of compounds.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

The product obtained from several aliphatic iodides has been examined, but no pure compound has hitherto been isolated and identified. Some of the compounds produced react with sodium bisulphite, hydroxylamine, and substituted hydrazines, and are very probably ketonic.

The product of the action of phenyl magnesium iodide on nickel carbonyl when treated with acids gave rise to a mixture which was found to consist chiefly of *diphenyl* and *benzoin*. The former is very readily produced from phenyl magnesium iodide, and is frequently observed among the products of its reactions. The formation of benzoin has an important bearing on the constitution of nickel carbonyl.

All the reactions of nickel carbonyl which have been described previously can be equally well explained by means of either of the two formulæ,—

which have been proposed; but benzoin could be produced in a much simpler way from a compound with the second formula. Its production may therefore be regarded as evidence in favour of this.

The following suggestion as to the course of the reaction is to be regarded as purely tentative:—

The product, $\begin{array}{c} \text{C}_6\text{H}_5 > \text{C}-\text{OH} \\ | \\ \text{C}_6\text{H}_5 > \text{C}-\text{OH} \end{array}$, is supposed to undergo molecular transformation into benzoin.

DUTY-FREE ALCOHOL FOR INDUSTRIAL PURPOSES.

THE Chancellor of the Exchequer has appointed the following gentlemen to serve as members of a Committee to inquire into the use of duty-free alcohol for industrial purposes:—Sir Henry Primrose, K.C.B., C.S.I., chairman; Professor Sir William Crookes, D.Sc., F.R.S.; Sir W. H. Holland, M.P.; the Hon. J. Scott-Montagu, M.P.; Lothian D. Nicholson, Esq.; Dr. W. Somerville; Dr. T. E. Thorpe, C.B., F.R.S.; Thomas Tyrer, Esq.

The terms of reference are:—

“To inquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufactures, and, in particular, into the operation of Section 8 of the Finance Act, 1902; and to report whether the powers conferred upon the Commissioners of Inland Revenue by this section permit of adequate facilities being given for the use of spirits in manufactures and in the production of motive power, or whether further facilities are required; and, if it should appear to the Committee that the present facilities are inadequate, to advise what further measures could be adopted without prejudice to the safety of the revenue derived from spirits, and with due regard to the interests of the producers of spirits in the United Kingdom.”

All communications should be directed to Sir Henry Primrose, K.C.B., at Somerset House, Strand, W.C.

Sir Henry Primrose is Chairman of the Board of Inland Revenue. Sir William Crookes is a Past President of the Chemical Society, and was in 1898 President of the British Association. Sir W. H. Holland is the Liberal member for the Rotherham Division of Yorkshire, and Vice-President of the Associated Chambers of Commerce. The Hon. J. Scott-Montagu is well known for his interest in the use of alcohol for motive purposes. Mr. Nicholson belongs to the Thames Bank Distillery, and is Chairman of the London Distillers' Association. Dr. Thorpe is Director of the Government Laboratories. Dr. Somerville is an Assistant-Secretary at the Board of Agriculture. Mr. Tyrer is Managing Director of the Stirling Chemical Works at Stratford, and is one of the largest manufacturers of alcohol and fine chemicals in the kingdom.—*The Times*.

CONDENSATION OF HELIUM AND HYDROGEN BY CHARCOAL.

By Sir JAMES DEWAR, F.R.S., &c.

In a preceding paper I explained that wood carbon absorbed large quantities of gases at low temperatures, and could be used to produce very high vacua. I have continued my researches on this subject, in order to ascertain the specific behaviour of hydrogen and helium to charcoal when the latter is cooled to the boiling-point of liquid hydrogen.

For this series of experiments I utilised the same apparatus as previously employed for spectroscopic observations, with the addition of a small condenser containing 1 or 2 grms. of wood carbon attached to each of the tubes. Two tubes were filled, one with hydrogen the other with helium, at atmospheric pressure. The little charcoal condensers were now plunged in liquid hydrogen, with the result that the vacuum became so high that no electric discharge would pass in the tube filled with hydrogen.

This experiment is similar to those performed with tubes filled with nitrogen and oxygen, liquid air being used as the cooling agent.

When the tube filled with helium has its charcoal condenser cooled in liquid hydrogen, the vacuum produced is high enough to obtain the phenomenon of phosphorescence under the action of the discharge. After being assured of the absorption of the helium, I put two tubes containing helium from different sources in the liquid hydrogen, and subjected them to the action of liquid hydrogen boiling under exhaustion, and finally attained the temperature of 15° absolute. In each case the vacuum resulting from the occlusion of the helium was so high that a coil giving a spark of 4 c.m. in air had to be used to obtain an intermittent phosphorescent discharge. The tube only gave a continuous spectrum due to the glass.

We may conclude from these experiments that carbon is a good absorbent of helium at 20° absolute, and is a still better one at 15° absolute.

From a number of comparative experiments made with hydrogen it seems that the boiling-point of helium is about 6° absolute.

I intend to continue the experiments, and to find out what the gaseous residue remaining in such tubes can be. The present researches, however, confirm my former conclusions that the boiling-point of helium is not below 5° absolute.

During the course of these experiments, and using the method of condensation by carbon, I have been able to prove the existence of small traces of helium in the gases dissolved in rain-water, sea-water, and even in Thames water.—*Comptes Rendus*, vol. CXXXIX., No. 7, p. 421.

REFRACTIVE INDEX OF CLOVE OIL.

By W. H. SIMMONS.

THE utility of the refractive index in the examination of essential oils has been subject to much criticism, but there can be little doubt that with many oils the figure is a very useful one, and this particularly appears to be the case with clove oil. The principal constituent of this oil is, of course, eugenol, which has a relatively high refractive index, viz., $n_D^{20} = 1.5412$, and I have found, from the examination of several samples of the oil, that with pure oils the refractive index is approximately proportional to the eugenol content, so that—in view of the rapidity with which the determination can be made—it should be of much value to distillers of clove oil, who, I understand, now usually take the specific gravity and phenol content of their finished products. With samples whose genuineness cannot be guaranteed, however, it is not safe to base an opinion on the refractive index only, as is shown by No. 9 in the accompanying table, which is evidently grossly adulterated, judged by the high specific gravity compared with its low proportion of eugenol, though from its refractive index it might be expected to contain about 86 to 88 per cent of phenols.

No.	Specific gravity, $15/15^\circ$.	Rotation, [α] $_D^{20}$.	Refractive index, n_D^{20} .	Phenols, per cent.

NOTICES OF BOOKS.

Die Elektrochemische Reduktion der Nitroderivate Organische Verbindungen. ("The Electro-chemical Reduction of the Nitro-derivatives of Organic Compounds"). by JOH. MÖLLER. Halle-a-S.: Wilhelm Knapp. 1904.

THE technical importance of the results obtained on applying the methods of electro-chemistry to organic substances in general is ample justification for the preparation of such a book as this, quite apart from the questions of more purely scientific interest which are discussed in it; and the treatment of nitro bodies may be regarded as a special and important province of organic electro-chemistry, which up to the present has not received sufficient recognition, to judge from the publications exclusively devoted to it which have appeared. This work aims at providing a complete and accurate presentation of the subject both from experimental and theoretical points of view, and it may be said to fulfil its aim admirably. Very numerous results obtained on electrolysis of nitro bodies, both in acid and alkaline solution, are given in it, with all details relating to the performance of the experimental work; also the three theories of Haber, Löb, and Chilesotti, as applied to aromatic substances, are explained and discussed at some length.

Gesammelte Abhandlungen von Robert Bunsen. ("The Collected Works of Robert Bunsen"). Edited by WILHELM OSTWALD and MAX BODENSTEIN. Three Volumes. Leipzig: Wilhelm Engelmann. 1904.

THE German *Gesellschaft für Angewandte Physikalische Chemie* bearing Bunsen's name has commissioned Prof. Ostwald and Dr. Bodenstein to edit this collection of all the great chemist's publications, and in this edition all papers written by Bunsen are arranged in approximately

chronological order. It includes also the whole of the second edition of his "Gasometrische Methoden" which first appeared in 1857. The speech delivered before the London Chemical Society by Sir Henry Roscoe shortly after Bunsen's death contains a specially interesting account of his life, with some correspondence which passed between the two chemists, and it need hardly be said that it gives a very sympathetic view of his life and work. The notices which appeared in the *Zeitschrift für Anorganische Chemie* and in the *Zeitschrift für Elektrochemie* on the occasion of his death are also included. Inasmuch as the value of Bunsen's contributions to our knowledge of physics and chemistry are thoroughly recognised, and his work runs little risk of being under-estimated, such a collection as this calls for no special criticism, for it goes without saying that it will recommend itself to all who are interested in chemistry, and will well repay perusal in the amount of information and instruction which it will be found to contain.

Practical Chemistry. By P. A. ELLIS RICHARDS, F.I.C. London: Baillière, Tindall, and Cox. 1904.

THIS small book has been written specially for the use of students of medicine and dentistry, and contains all that is required by candidates for the Conjoint Board Preliminary Scientific Examination, besides additional matter for the Preliminary Scientific of London University. Thus it includes the qualitative analysis of simple salts and easy mixtures, with a few very useful notes on some salts presenting special difficulties, and also describes the preparations of certain salts as required in the syllabus of the Conjoint Board, besides a few others. The section on volumetric analysis is wonderfully clearly written, and no beginner could fail to understand the explanations in this part, which is on the whole the best in the book. The pages on elementary practical toxicology contain an account of the general reactions of the more common poisons, with a description of the methods used for the detection of a poison, both in a simple solution and also an organic mixture.

Die Neuren Strahlungen. ("The Newer Rays"). By HANS MAYER. Second Edition. Mähr-Ostrau: R. Papauschek. 1904.

THIS short account of the theoretical and experimental results obtained during the investigation of the cathode, canal, and Röntgen rays, and the phenomena of radio-activity generally, is clearly written and eminently readable; the facts and theories stated in it are judiciously chosen and well balanced, and the work of various investigators is very fairly described, so that the reader ought to get a good idea of the real part played by the several workers in the development of the most modern theories. The book is more scientific than the usual run of popular expositions of this kind, and even the uninitiated reader will gather from it some clear ideas of the new theories regarding the constitution of matter and of the theory of electrons. The chief fault to be found with it is the author's disregard for the need of constantly emphasising the very important difference between results which may be safely regarded as thoroughly well established and others which are still in dispute; as, for example, in the case of the wave-length measurements of X-rays and the atomic weight of radium. However, the book has evidently met with some success, for the first edition was exhausted within a month from its appearance.

Das Königliche Materialprüfungsamt der Technischen Hochschule, Berlin. ("The Royal Testing Office of the Technical High School at Berlin"). By A. MARTENS and M. GUTH. Berlin: Julius Springer. 1904.

THIS volume, prepared in commemoration of the opening of the new buildings at Gross-Lichterfelde West, gives an elaborate description of the working of this department of the Technical High School at Berlin. The arrangements

of the buildings are fully explained, and an account of the history of the department given at great length. The communications which have issued from the institution during the years 1883 to 1903, which give a good idea of its great activity, are enumerated and indexed, and numerous tables and statistics are contained in the text. The descriptions of the laboratories and their appliances, which are copiously illustrated by photographs and plans, will be found to contain many useful hints for those who are interested in the fitting-up of similar institutions, the very latest improvements in structure and arrangement having evidently been adopted in this most palatial building. The enlarged space now at the disposal of the institution will give its workers increased opportunities of energetically extending the valuable work which is being done in it, especially on the purely scientific side, the importance of which is duly recognised; and the chapter at the end of the book on the aims of the institution for the future shows the standard of usefulness which the Director has put before him, and the special means which are to be taken to come up to this high standard. It is evident from the whole book that nothing could be done to add to the convenience of those who are engaged in this department of the Technical Hochschule, for they are surrounded by the most favourable circumstances for doing work of permanent and high scientific value.

Fortieth Annual Report on Alkali, &c., Works. By the CHIEF INSPECTOR. London: Printed for His Majesty's Stationery Office by Messrs. Eyre and Spottiswoode. 1904. Pp. 183.

THIS report, under the Alkali, &c., Works Regulation Acts of 1881 and 1892, comprises the proceedings during the year 1903, presented to the Local Government Board and to the Secretary for Scotland.

The number of works now registered under the Acts in England, Ireland, and Wales is 1034. Of these 75 only are works decomposing salt, and so scheduled as alkali works, while the remaining 959 carry on processes which are scheduled or subject to registration. There are also 127 works registered in Scotland, bringing the total number of works registered in the United Kingdom to 1161.

During the year 1903, the total number of visits made by the Inspectors was 4838, while 5211 tests were made, and in only one case was it necessary to take proceedings for recovery of penalty for infraction of the provisions of the Act. A severe escape of noxious and offensive gases of very acid and irritating character was found at a chemical manure works; the plant was in a totally unfit condition for work, being much out of repair.

A Bill to amend and consolidate the Alkali Acts was read a first time in the Session of 1903; various conferences were held during the recess, as the result of which a new Bill was presented in 1904.

Viewed as a whole it may be said that the conduct of the Alkali and Wet Copper Works, the longest under inspection under the Alkali Acts, has given little ground for complaint. For individual cases, however, there has been much ground for anxiety, and serious representations had to be made in three cases, that if the escape of muriatic acid was continued penalties would be pressed for.

There has been almost complete absence of complaint during the year of escape of chlorine gas from the large manufacturing operations in which it is evolved and subsequently absorbed.

An interesting and valuable investigation has been conducted by Mr. Linder, to determine the conditions most favourable for the complete absorption of H_2S and SO_2 by "waste" slurry, either alone or in conjunction with added lime; this is given in detail on pp. 13-18.

The average escape of acid gases of sulphur and nitrogen from exits of sulphuric acid works, in which this manufacture is carried on by the lead chamber process, is still maintained at a figure that must be regarded with satisfaction, as indicating the continued care and attention that, in a large number of works, are devoted to the conduct of

this manufacture on the best and most economic lines. The average escape of the 211 exits tested varies but slightly from the figures already given for the years 1901 and 1902, viz., 1.248 grains of SO_2 per cubic foot.

The results of the investigation presented in last year's report on the testing of acid gases escaping from the chamber process of sulphuric acid manufacture have received some attention at the hands of manufacturers, and through the courtesy of Messrs. Chapman, Messel, and Co., of Silvertown, Mr. Linder has been enabled to prosecute some further investigations on the reactions in the sulphuric acid chambers and connections at various points, with the view of ascertaining if any evidence could be obtained of the existence at any point in the chamber system of the sulphazotised bodies, hydroximidol-sulphuric or hydroxyamido-sulphuric acids, the latter being one of the products of the hydrolysis of the former.

The important class of work comprising sulphate and muriate of ammonia and gas-liquor works continues to increase in number; the tendency for gas works to manufacture their own residual products in place of disposing of the crude materials is certainly on the increase, and it is pointed out that the number of such processes forms the largest contribution by far to the total of 1456.

Through the courtesy of managers, the Chief Inspector is again able to give the figures for the amount of sulphate of ammonia produced in the United Kingdom; these are given on p. 30.

With regard to salt works it is pointed out that the muriatic acid escaping into the atmosphere from this class of works is maintained well within the maximum permitted, viz., one-fifth of a grain per cubic foot of chimney gases. The expectation that during 1903 some opportunity of observing the results of applying gaseous firing to salt pans has not been fulfilled; the plant, however, is in a forward state of preparation.

CORRESPONDENCE.

PATENT LAW, 1902.

To the Editor of the Chemical News.

SIR,—The Board of Trade has just issued an order bringing into force on January 1st next the Government examination system for patents set forth in the Patent Law of 1902, and from January 1st, 1905, reducing the period of provisional protection from nine months to six. The system of examination thus instituted is much less perfect than those of other countries, as the Examiner has merely to search through the British patents of the immediately preceding fifty years to see if in these there be, in his opinion, any anticipation of the invention set forth in the complete specification. This report is forwarded to the Comptroller, and if the Comptroller be of the opinion (from this report) that the invention is partly or wholly anticipated, the applicant is informed of the anticipation, and has the option of a personal hearing, or of amending the specification to the satisfaction of the Comptroller, or in default of either, the Comptroller determines whether a reference to any and if so what prior specifications must be made in the specification by way of notice to the public. Against his decision there will be an appeal to the Law Officer. The Examiners' reports will be kept strictly secret from all but the applicant and his agent, but this examination must not be held in the slightest to guarantee in any way the novelty of the invention or the validity of the patent, as of course the prior publication of the invention in other documents open to the public in England prior to the date of the application, or the prior public use of the invention, would be equally as fatal to the validity of the patent as the publication of the invention in a prior British specification.—We are, &c.,

W. P. THOMPSON and Co.,
Chartered Patent Agents.

6, Lord Street, Liverpool,
Sept. 1st, 1904.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 6, August 8, 1904.

Theory of Dilute Solutions Based on van't Hoff's Law.—E. Ariès.—By applying the phenomena of osmosis to dilute solutions M. van't Hoff deduced a law from which a complete theory of such solutions can be evolved.

Vanadium Steels.—Léon Guillet.—The author's researches on the subject of vanadium steels show:—1. That such steels produced at 900° and slowly cooled are not so fragile as ordinary steels containing the same amount of carbon, and that to the same resistance they are decidedly less fragile; (2) the steels containing a large percentage of vanadium, and in which all the carbon is in the state of carbide, are absolutely heterogeneous. This is most probably due to the vanadium carbide which, pre-existing in the bath and having a very small density, tends to reappear on the surface. In all cases it can be affirmed that the only interesting vanadium steels are those which contain less than 0.7 per cent of vanadium.

Certain Derivatives of Pentabasic Phosphoric Acid.—P. Lemoult.—When PCl_5 is totally anilinated the only tetranilide product obtained is of the type $\text{Cl}-\text{P}(\text{NHR})_4$. The reactions of such compounds with regard to sodium alcohols vary with the nature of R. If R is a phenyl the phosphonitrated base $\text{C}_6\text{H}_5-\text{N}=\text{P}(\text{NHC}_6\text{H}_5)_3$ is obtained. If, on the contrary, R is a homologue of phenyl (e.g., *o*-tolyl or *m*-xylyl) the products obtained vary with the alcoholate used whilst keeping the same general properties. These are the arylamide-phospho ethers of formula $\text{R}'-\text{O}-\text{P}(\text{NHR})_4$, where R' is an alcoholic radical.

Dimethylpyroarsenic Acid.—E. Baud.—The author proves the existence of a pyroarsenic acid corresponding to pyroarsenic acid, which is prepared by heating anhydrous monomethylarsenic acid on an oil-bath at 130°–140° in a current of dry hydrogen, when it loses half a molecule of water,—

The compound obtained is dimethylpyroarsenic acid. This acid decomposes on a rise of temperature into methylic alcohol and arsenious anhydride.

Bulletin de la Société Chimique de Paris.
Series 3, Vol. xxxi., No. 3.

Influence of Gases on the Separation of Metals by Electrolysis. Separation of Nickel and Zinc.—MM. HOLLARD and BERTIAUX.—Already noticed.

The Optical Activity of Cellulose and its Nitrated Derivatives.—Leo Vignon.—The optical activity of cellulose has been examined by Bechamp and Levallois who found contradictory results; the latter chemist found that it was levogyre, while the former declared it to be inactive. The author concludes from his experiments that the question of deciding the optical activity of cellulose in its original state is not yet solved. He shows that, on the other hand, dinitro-oxycellulose (with C_6) is a dextrogyre substance, and he has measured its rotatory power in an ether-alcoholic mixture and in acetone.

Determination of the Carbonate of Sodium necessary for the Precipitation of the Lime and Magnesia in the Chemical Purification of Water.—Leo Vignon.—Already noticed.

The α -Dialcylhydropyridic Acids.—E. E. Blaise and L. Marcilly.—This paper deals chiefly with the α -dialcyl-

hydropyridic acids, and among them oxypivalic and α -methylcylhydropyridic acids:—

The author commences with the condensation of bromoisobutyrate of ethyl with trioxymethylene in the presence of zinc. The condensation takes place very easily when the conditions are favourable. It is even necessary to check the reaction by cooling the flask, otherwise the condenser would not be able to condense the whole of the benzene. A series of operations was made with 1000 grms. of bromoisobutyrate of ethyl, and the author obtained 391 grms. of an ether passing over at 84°–86° under 16 m.m., 19.5 grms. passing over at 110°–116° under 12 m.m., 50 grms. passing over at 150°–166° under 15 m.m., and 40 grms. of undistillable residue from which he has not been able to isolate any body. He has examined the above fractions, and describes them in full.

Oxypivalic Acid.—L. Marcilly.—The author has already described the preparation and purification of pure oxypivalic acid. Its constitution has been determined by oxidation, and the complete oxidation furnishes dimethylmalonic acid. The author has examined a large number of derivatives and compounds of oxypivalic acid, and describes them all in a very long paper.

A New Triiodised Phenol.—P. Brenans.—Already noticed.

The Oxidation of Orthonitrotoluene.—C. Lauth.—The author has conducted a series of experiments with the object of preparing ortho-nitro aldehyde from ortho-nitro toluene, and though he did not succeed in his attempt he observed several facts which are of interest. Among the numerous transforming reagents tried, only the acid oxidisers gave the aldehyde; this substance was not obtained either with the alkaline or neutral oxidising agents, with the exception of ozone.

The Phthalate and Mellate of Bismuth and Pyrophosphoric Bismuth.—Paul Thibault.—The three phthalic acids do not all react in the same manner on oxide of bismuth, still they have a common property; they do not act on the hydrated oxide of bismuth, and the orthophthalic acid only acts on the anhydrous oxide, while the isophthalic and terephthalic (meta and para) acids leave this oxide unattacked. To obtain phthalate of bismuth, the anhydrous oxide is treated with an excess of orthophthalic acid in the presence of boiling water for ten or twelve hours; at the end of this time a microscopic examination no longer reveals the presence of opaque yellow needles of the anhydrous oxide; filter hot, and wash with strong alcohol, or better with a mixture of alcohol and ether. A white crystalline body is left, decomposed by water, insoluble in the ordinary solvents, soluble in the mineral acids with the liberation of phthalic acid, and the formation of a corresponding salt of bismuth. Mellic acid in aqueous solution of moderate strength acts very rapidly when heated on both the anhydrous and the hydrated oxides of bismuth. The product is a white crystalline body not decomposed even by boiling water or alcohol, &c. By decomposing crystallised mellate of bismuth by heat *in vacuo* a pyrophosphoric bismuth was obtained.

Detection of Acetone in Urine.—M. Vournasos.—Minimal quantities of acetone can be detected in urine by means of the same reagent already described for the detection of lactic acid in gastric juice. This reagent is a solution of iodine in methylamine or aniline. It acts on acetone in the same manner as on lactic acid; that is to say, in alkaline solution it causes the formation of iodoform, which simultaneously enters into combination with the nitrogen of the amine, giving rise to an isonitrite; in this case the isocyanide of methyl (methylcarbonylamine).

Estimation of Organic Matters in Water. Drawbacks to the Use of Filter-papers before Analysis.—C. Lenormand.—Already inserted in full.

MISCELLANEOUS.

Important Experiments in Radio-activity.—We are indebted to the *Chemist and Druggist* for the following important cablegram from their Representative in New York:—

"New York, September 12.

"Since the Banquet at the Waldorf-Astoria, Sir William Ramsay has courteously revised for me my version of the important statement which he then made. I therefore add this to my previous messages:—

"Sir William Ramsay says experiments are in progress [in the University College Laboratories—Ed. C. & D.] with radio-active substances, the results of which seem to show that we are on the brink of discovering the synthesis of atoms. This may lead us to the discovery of the ordinary elements. These may be the products of the breaking-down of radio-active elements of high atomic weight, as when radium changes into helium."

Estimation of Tannin with Ferric Salts.—M. RUOSS. —The German Commission for the Unification of the Methods for the Estimation of Tannin in 1883 adopted officially the Loewenthal-von Schroeder process. This process consists of determining the difference of the oxidising power between the raw solution and the solution filtered through powdered skin. Now, powdered skin absorbs a considerable amount of colouring matter which acts on permanganate. The amount of cameleon used is not, therefore, in proportion to the real amount of fixed tannin. The author proposes to precipitate the tannin by means of a ferric salt under definite conditions. A tannate of iron is formed of constant composition; the amount of tannin it contains is deduced from the weight of oxide of iron obtained on calcination. *Reagents.*—(1) Solution of crystallised carbonate of soda (71·36 per thousand); (2) solution of ferric sulphate at 50 grms. per litre; (3) solution of 5 grms. of tartrate of soda in 1 litre of acetic acid at 30 per cent. The method of working is as follows:—Fifty c.c. of a solution of tannin (about 4 grms. per litre) are treated with 10 c.c. of carbonate of soda and 10 c.c. of ferric solution, then with 25 c.c. of acetic tartrate of soda. Boil, filter, and wash with warm water. The precipitate is dried and calcined; the sesquioxide of iron is weighed. The weight found, multiplied by 4·024, gives the proportion of tannin in the 50 c.c. taken.—*Zeit. Anal. Chem.*, vol. xli., p. 717.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

The Post of STEWARD in the Chemical

Laboratories of the School of Pharmacy is now vacant.—Applications, stating age and experience, and accompanied by one or more testimonials, should be sent at once to Professor CROSSLEY, 17, Bloomsbury Square, London, W.C.

UNIVERSITY OF GLASGOW.

ADDITIONAL EXAMINERSHIPS.

The University Court of the University of Glasgow will shortly proceed to appoint the following additional Examiners:—

- (a) For Degrees in Arts and Science.—One Examiner in MATHEMATICS and NATURAL PHILOSOPHY. Annual salary, £60.
- (b) For Degrees in Arts, Science, and Medicine.—One Examiner in CHEMISTRY. Annual salary, £50.
- (c) For Degrees in Medicine and Science.—One Examiner in PHYSICS. Annual salary, £50.

The appointments will be for three or four years from January 1st, 1905, and, in addition to the above-mentioned salaries, hotel and travelling expenses will be paid.

Candidates should lodge twenty copies of their application and testimonials with the undersigned on or before NOVEMBER 12th, 1904.

ALAN E. CLAPPERTON,

91, West Regent Street, Secretary, Glasgow University Court, Glasgow.

SOUTH-WESTERN POLYTECHNIC,

MANRESA ROAD, CHELSEA, S.W.

Principal—S. SKINNER, M.A.

THE TECHNICAL COLLEGE re-opens

OCTOBER 3rd, 1904.

THE ENTRANCE EXAMINATION will be held on SEPTEMBER 19-20, 1904.

Three Free Studentships of the value of £45 are awarded on the results of this Examination.

The Courses are divided into two Sections:—

- (1) LONDON UNIVERSITY COURSES; and
- (2) TECHNICAL COURSES.

LONDON UNIVERSITY COURSES.

These Courses are designed to prepare Students for the London B.Sc. Degree in the subjects mentioned below:—

Matriculation Course (one year) . Fee, £12 10s. per Session.

Intermediate Science Course (one year) £15 ..

B.Sc. Courses by recognised Teachers for Internal Students of two years' duration in the following subjects:—Mechanical and Electrical Engineering, Mathematics, Physics, Chemistry, Botany, and Geology.

Fee for the Engineering or Science Degree Course, £15 per Session.

TECHNICAL COURSES.

These Courses are of three years' duration, and give a thorough training to those who wish to become Electrical or Mechanical Engineers, or Consulting or Industrial Chemists.

Electrical Engineering . . . Fee, £15 per Session.
Mechanical Engineering . . .
Applied Chemistry . . .

Further information may be obtained from the Day Prospectus, price 1d., by post 3d.

Complete EVENING COURSES are also provided, of which full particulars may be obtained from the Evening Prospectus, price 1d., by post 3d.

BOROUGH POLYTECHNIC INSTITUTE,

103, BOROUGH ROAD

(Close to the Obelisk, Blackfriars Road, S.E.).

EVENING CLASSES (LECTURES AND PRACTICAL LABORATORY WORK), commencing MONDAY, OCTOBER 3rd, 1904.

CHEMISTRY.—F. MOLLWO PERKIN, Ph.D.,

Assisted by H. B. LAW, B.Sc., and A. J. HALE.

INORGANIC.—Elementary: Tuesdays and Thursdays, 7.30—10. Advanced: Mondays and Wednesdays, 7.30—8.30. Special and Honours: Lectures—Mondays, 7.30—8.30; Laboratory—Mondays, Tuesdays, Wednesdays, and Fridays. Fees, 10s. to 15s.

ORGANIC.—Elementary: Tuesdays and Thursdays, 7.30—10. Advanced: Mondays and Wednesdays, 7.30 to 10. Honours: Lectures—Tuesdays, 8.30—9.30; Laboratory—Monday, Tuesday, Wednesday, and Friday. Fees, 10s. to 20s.

ELECTRO-CHEMISTRY.—Lectures—Fridays, 7.30—8.30; Laboratory Work—During the day, at times to be arranged. Fee, 70s.

SATURDAY MORNING CLASS FOR PRACTICAL CHEMISTRY, 9.30—1. Fee, 10s.

ELECTRICITY & MAGNETISM.—JOHN

HENDERSON, D.Sc., A.I.E.E., assisted by H. S. SAUNDERS.

ELEMENTARY (Lectures and Laboratory)—Mondays, 7.30—10. **ADVANCED COURSE.**—Tuesdays, 7.30—10.

HONOURS COURSE.—Mondays, 9.10—Wednesdays, 7.30.

ELECTRICAL AND MAGNETIC MEASUREMENTS.—Fridays, 7.30—10.—This Course is intended for Electrical Engineers, Instrument Makers, and others engaged in Electrical Work. Fee for the Session, 10s. and 12s.

Full particulars may be obtained on application.

C. T. MILLIS, Principal, Education Department.

COVERS FOR BINDING.

Cloth, Gilt-lettered Covers for Binding the Half-yearly Volumes of the

CHEMICAL NEWS

may now be obtained. Prices 1/6 each (post free 1/8). Volumes Bound in Cloth Cases, Lettered, and Numbered at 2s. 6d. per volume

THE SIR JOHN CASS TECHNICAL INSTITUTE.
JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.

EVENING CLASSES IN CHEMISTRY, METALLURGY, PHYSICS, and MATHEMATICS.Designed to meet the requirements of those engaged in
CHEMICAL, METALLURGICAL, and ELECTRICAL
INDUSTRIES,
and in trades associated therewith.Also preparation for the B.Sc. Examination of London University.
Every facility for Special and Advanced Practical Work in well-
equipped Laboratories, both in the Afternoon and Evening

CHEMISTRY	CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.
PHYSICS.	R. S. WILLOWS, D.Sc., M.A.
METALLURGY.	C. O. BANNISTER, Assoc.R.S.M.
MATHEMATICS.	G. M. K. LEGGETT, B.A.

CLASSES IN METALLURGY.

GENERAL METALLURGY.

THE METALLURGY OF GOLD, SILVER, and LEAD.

FUEL and REFRACTORIAL MATERIALS.

METALLOGRAPHY, including PYROMETRIC WORK.

ASSAYING.

ANALYTICAL CHEMISTRY.

Including ELECTROLYTIC and GAS ANALYSIS.

Each Course of Lectures will be accompanied by suitable Laboratory Work.

GLASS BLOWING.

A series of Courses of Instruction will be given during the Session by Mr. A. C. COSSOR.

NEW SESSION begins MONDAY, SEPT. 26th.The Institute is readily accessible, and near to Fenchurch Street, Liverpool Street, Broad Street, and Metropolitan Railway Stations.
For details of the Classes apply at the Office of the Institute, or by letter to the PRINCIPAL.W. H. DAVISON, M.A.,
Clerk to the Governing Body.**THE POLYTECHNIC,**

309, REGENT STREET, W.

UNIVERSITY OF LONDON PREPARATION CLASSES.

Full Courses of Instruction for Matriculation,Inter. Arts, Science, and Engineering, and Final Arts.
Special Courses for Final B.Sc. in Mathematics, Physics, and Chemistry.

Examinations are held at the above Institute.

NEXT TERM commences SEPTEMBER 16th, 1904.

Courses are so arranged that Students can do the work on Saturday and one evening per week.

Full particulars can be obtained on application to the DIRECTOR OF EDUCATION.

CITY OF LONDON COLLEGE,WHITE STREET and ROPEMAKER STREET,
MOORFIELDS, E.C.**MICHAELMAS TERM commences OCTOBER 3rd.****CLASSES and LABORATORY WORK in**
CHEMISTRY, PHYSICS, BIOLOGY, BOTANY,
GEOLOGY, and PHYSIOLOGY. Special preparation for the
Examinations of the Pharmaceutical Society, The Conjoint Board.
Complete Courses for University Matriculation and Inter. and Final
B.Sc., meeting during the Evening and on Saturday.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

REDRUTH SCHOOL OF MINES, CORNWALL.**Session 1904-1905 begins September 7th.****A "Mining Certificate" is awarded to Students**
passing successfully through the School Course.**PRACTICAL MINING CLASSES**, under the instruction of
Capt. WILLIAM HAMBLEY (late Government Inspector, South Africa)
Distinctions in Mine Surveying in Open Examination five years in
succession, including five Medals and Prizes, being all the awards of

VOL. XC., No. 2339.

THORIUM; CAROLINUM, BERZELIUM.*

By CHARLES BASKERVILLE, Ph.D., F.C.S.

Synopsis.

THIS paper presents a brief historical account of the discovery of thorium and the questions raised as to its elementary character.

The published evidence is considered in conjunction with experimental data obtained, and the conclusions arrived at that thorium is not a primary radio-active body.

The complex nature of thorium is proved by the conduct of salts with certain organic bases, as phenylhydrazine, for example. Fractions were added giving atomic weights from 212 to 252, the original being 232.5.

Pure thorium oxide from several sources was converted into the chloride by heating it, mixed with pure sugar carbon within quartz tubes, during the passage of dry chlorine. A volatile chloride, "weisser dampf" of Berzelius was obtained, decreasing in amount according to the duration and temperature of the reaction. The purified, delicately green oxide obtained from this gave a specific gravity of 8.47, and the element berzelium an atomic weight of 212 (tetrad).

The temperature of the porcelain tube was raised and thorium tetrachloride distilled away. The residue in the carbon boat on purification gave a greyish pink oxide with a specific gravity of 11.26 and an atomic weight of (tetrad) 255.6 (carolinum). The new thorium, or that in a large measure freed from the berzelium and carolinum, gave an atomic weight of 220.6, and a white oxide with a specific gravity of 9.2. The original thorium gave atomic weights 232.5 to 232.6, and its oxide had a specific gravity of 10.5.

The original thorium dioxide phosphoresces under the influence of ultra violet light, as does zirconium dioxide. Berzelium and carolinum oxides do not respond to this stimulus, while the new thorium glows with increasing luminosity according to the decrease of the novel substances. All these bodies are radio-active.

Certain chemical differences are noted, as, for example, the conduct of their salts with organic bases, fumaric acid, &c. Carolinum oxide is soluble in concentrated hydrochloric acid, while berzelium and thorium oxides are not.

Spectral data are wanting; in fact, the limited portions of the spectra (arc and spark) mapped show the bodies identical. The materials are not yet sufficiently pure, nor the spectral data sufficiently complete, to warrant final acceptance, although the preponderance of evidence is favourable to the assumption of the existence of two new members of the family of chemical elements.

The marvellous phenomena of radioactivity, accounts of which have filled our chemical and physical literature for the past six years, have stimulated numerous investigators to take part in asking a solution which would be satisfactory, and not wholly drive us from our former conceptions of the fundamental laws of the conservation of matter (whatever it may be) and energy (however we may measure it). Naturally such have had to do with thorium, the radio-activity of which was independently noted by G. C. Schmidt (*Wied. Ann.*, 1898, lxx., 141) and Curie (*Comptes Rendus*, cxxvi., 15; see also Mme. Curie's Thesis presented to the Faculté des Sciences de Paris, 1903), and studied extensively from both points of view by Rutherford, Soddy,

and their co-workers (many papers in *Philosophical Magazine*; *Proc. Chem. Soc.*, 1902, xviii., 2, and *Transactions*, 1902, lxxxi.-lxxxii., 476, &c.), Giesel (*Ber.*, 1901, xxxiv., 3776), Hofmann and Zerban (*Ber.*, 1902, xxxv., 533 and 1457, and xxxvi., 3093), Owens (*Phil. Mag.*, October, 1899), Pegram (*Physical Review*, 1903, xvii., 424), and others, as well as myself (*Journ. Am. Chem. Soc.*, 1901, xxiii., 761).

Other communications upon our researches on thorium have been withheld in the hope of early reaching a solution of the difficult problems involved in an investigation of that element. While the work is far from complete—is any scientific work complete?—we think sufficient evidence of the complexity of the element has been accumulated to warrant definite statements, and excuse us from having had recourse to that "bastard *a priori* method," according to Herbert Spencer, namely, drawing conclusions from insufficient data. Further, on account of the numerous investigations that are coming out upon the elements of high atomic weights, it is well to offer our observations that they may be of service to others.

(NOTE.—When my first preliminary paper on the complexity of thorium was made known publicly, in a note I gave as an excuse for publishing the work, a statement of the fact that I had written Professor Bohuslav Brauner that I thought I had brought about a breaking down of the element. I requested a sample of the very pure body he had prepared and used in his excellent atomic weight determinations that I might check my work. I received no acknowledgment of the letter, and would not know to this day that it had been received but for what followed. Dr. Brauner shortly published some work which clearly pointed to thorium being composite. Having devoted some years of study to the work myself, and following entirely different lines, I immediately, within eight days, at the first public opportunity, presented my paper. For fear I might be misunderstood, the facts outlined above were made known. In a letter to the Editor of the CHEMICAL NEWS Dr. Brauner took exception to my statement, assuming an intimation on my part that he had taken advantage of information contained in a private letter. The letter, in which I gave no details of the method of procedure, was quoted from (so it was received); furthermore, an excuse was given for not having replied to the letter that I was interfering with his field. Apparently a large number have interfered with that field since my publication. I purposed saying nothing regarding Professor Brauner's letter, but on account of the earnest solicitation of many friends the above statements are made known. It was utterly foreign to my mind to cast any reflections upon Professor Brauner. I appreciate most keenly his beautiful researches carried out in the rare earths, in which field that savant ranks as a master. I must object, however, to his having the field reserved. In fact, our work was carried out upon entirely different lines and similar conclusions reached. While it is only human that one should care to have his work appreciated, yet I am not engaged in scientific work for the credit alone).

In 1817 Berzelius ("Afhandl. i. Physik. Kemi. och Mineralogie," vol. v., p. 76; *Ann. Chim. Phys.*, v., 8; *Schweigger's Journ.*, xxi., 25), while investigating gadolinite from Korarvet and another mineral from Finbo, believed he found an unknown oxide similar to zirconia, and called it "thorine," after the mythological Scandinavian god of thunder, Thor. This master chemist, marvellously accurate, especially for the time, soon learned ("K. Vet. Acad. Handl.," vol. ii., pp. 4, 315; J. B. Berzelius, 1824, v., 112) that "thorine" was, in fact, a phosphate of the yttrium earths, and the name properly remained but a short time in chemical literature. In 1828 this same chemist ("K. Sv. Ver. Akad. Handl.," 1829, 11; *Ann. Phys.*, xvi., 388) found a new mineral, thorite, on the Island Lövö, near Brevig, Norway. In it he discovered a new element with which he revived the name thorium. Chydenius ("Kemisk undersökning af Thorjord och Thorsalter," Helsingfors, 1861; *Ann. Phys.*, cxix., 43) com-

* Presented before the New York Section of the American Chemical Society, April 8, 1904.

pleted the investigation, and Cleve (*Bull. Soc. Chim.*, 1874, [2], xxi., 116) revised the older data in 1874. Nilsson, with Krüss and Hillebrand, in many researches determined its atomic weight and secured unquestionable evidence as to its quadrivalence (*Ber.*, 1876, ix., 1056; 1882, xv., 2519, 2521, and 2537; 1883, xvi., 153; 1887, xx., 1665; *Ztschr. Phys. Chem.*, 1887, i., 301, &c.). Quite recently Wyruboff and Verneuil (*Bull. Soc. Chim.*, 1899, [3], xxi., 118), for reasons we need not enter into here, brought up the question of the quadrivalence of thorium which really depended largely upon the specific heat values obtained by Nilson (*Ber.*, 1883, xvi., 153). Biltz (*Liebig's Ann. Chem.*, 1904, cccxxi., 334) appears to have settled the matter by a rigid examination of the thorium acetylacetonate of Urbain (*Bull. Soc. Chim.*, 1896, [3], xv., 347).

In 1851 Bergemann (*Ann. Phys.*, 1851, lxxxii., 561) claimed to have found the oxide of a new element, "donarium," in the yellow variety of thorite, orangite, studied independently by himself and Kraut (*Ann. Phys.*, lxxxii., 568; *Liebig's Ann. Chem.*, 1851, lxxx., 267). Damour, the year following (1852), showed that donarium oxide was impure thorium oxide containing lead and uranium (*Ann. Phys.*, lxxxv., 555; *Liebig's Ann. Chem.*, 1852, lxxxv., 237). Bergemann shortly after observed that donarium and thorium were the same (*Ann. Phys.*, lxxxv., 556; *Liebig's Ann. Chem.*, lxxxv., 239). Berlin (*Ann. Phys.*, lxxxv., 556; lxxxvii., 608; *Liebig's Ann. Chem.*, 1852, lxxxiv., 238) arrived at the same conclusion, as did Delafontaine in 1863 (*N. Arch. Phys. Nat.*, xviii., 343; *Fahresher.*, 1863, p. 197).

Again in 1862 was thorium mistaken for a new element, namely, wasium, reported by Bahr in waste from Rönsholm ("Oefvers of K. Vet. Akad. Förhandl.," 1862, p. 415; *Ann. Phys.*, cxix., 572). The properties were very similar to those of thorium. Its existence not being clearly defined Nickles investigated it, maintaining it was a mixture of yttrium earths containing didymium and terbium (*Comptes Rendus*, lvii., 740). Delafontaine (*N. Arch. Phys. Nat.*, xviii., 369; *Fahresher.*, 1863, p. 201) insisted that it was a mixture of cerite earths, and Popp (*Liebig's Ann. Chem.*, cxxii., 364) asserted that it was nothing else than yttrium containing cerium. The discoverer shortly announced its identity with thorium, and proved its hypothetical existence (*Liebig's Ann. Chem.*, 1864, cxxii., 227).

There are not a few instances in the history of chemistry where scientific interest in some particular element or compound has been stimulated directly or indirectly through its commercial application and the demand thereby created. This is particularly true of thorium. The first German patent issued, Auer von Welsbach, marks the creation of unusual interest in the main constituent of his mantle (*Moniteur Scientifique*, 1894, [4], viii., 2, Patent List, p. 136, &c.). The improvement in the methods for its extraction on a large scale soon opened the gates wide for numerous researches. Although defined with precision through the work of those mentioned, Nordenskiöld (*Fahresher.*, xiii., 134), Petterson (*Comptes Rendus*, xci., 232), Troost and Ouyard (*Comptes Rendus*, cii., 1422), Berlin (*Pogg. Ann.*, 1863, cxix., 56), Delafontaine (*Liebig's Ann. Chem.*, 1864, cxxii., 100), Bakhuys-Roozebooms, Urbain, Jannasch, Brauner, Kosmann, Chavastelon, Muthmann, Locke, Dennis, Matignon, Böttinger, Moissan, and many others (vide the excellent "Index to the Literature of Thorium," Jöuet, Smithsonian Miscellaneous Collections, No. 1374), yet the anomalous conduct of certain of its compounds has caused serious questions by several investigators as to its elementary nature.

Chroustchoff reported an element associated with thorium in certain zircons and American monazite sands (*Journ. Russ. Phys. Chem. Ges.*, xxix., 206; *Chem. Zeit.*, 1890). Although little information is to be had as to this work, apparently the atomic weight, 220, was attributed to the element, which was detected spectroscopically. As Crookes remarks, "the spectrum of thorium is even more complicated than that of iron"; hence, further data are necessary. Auer von Welsbach insists that thorium is complex

(*CHEMICAL NEWS*, lxxxv., 255; *Journ. für Gasbeleucht. u. Wasservers.*, 1901, p. 661).

In 1898, as adverted to, G. C. Schmidt (*Wiad. Ann.*, lxx., 141) and Madame Curie (Madame Curie's Thesis, *Faculté des Sciences de Paris*, 1903) independently noted the radio-activity of thorium obtained from Bohemian pitchblende. Not long after the announcement of the Becquerel rays (*Comptes Rendus*, 1896, cxxii., 420, 501, 559, 689, 762, 1086), Crookes showed that by fractionating uranium nitrate with ether, compounds could be obtained which did not affect the photographic plate (*Proc. Roy. Soc.*, 1900, lxxi., 406). This indicated the separation of a new substance (Uranium X), and that radio-activity was not an inherent property of the element uranium as maintained by Madame Curie (*Comptes Rendus*, cxxvii., 175).

Soddy and Rutherford (*Proc. Chem. Soc.*, xviii., 121) demonstrated that only material carrying the β -rays was thus separated, and that the so-called inactive (to the photographic plate) uranium still gave off α -rays which ionize gases, and may be detected by the electrical method. Crookes, in the same paper, reported a few preliminary experiments on thorium compounds, and suggested "the possibility of separating thorium from its radio-active substance" (*loc. cit.*).

In 1899 Debiere separated from pitchblende a strong active substance which appeared to consist of titanium (*Comptes Rendus*, cxxix., 593). On more accurate investigation, however, he proved it to be nearer akin to thorium, and having secured an oxide 5000 times as active as uranium, he named the element actinium (*Comptes Rendus*, 1900, cxx., 906).

Debiere gives some four methods for separating this element, to wit:—Precipitation of weak acid solution by sodium thiosulphate, treating the hydroxide with hydrofluoric acid and potassium fluoride, precipitation of the neutral nitrate by hydrogen dioxide, and precipitating lead or barium sulphate in the liquid, whereby the active body is carried down. While quantitative physical data, as atomic weight, specific gravity, spectrum, &c., are as yet not to be had, the qualitative conduct of the radio-active properties are fairly well defined.

Hofmann and Zerban examined a number of minerals from which thorium is obtained, and proved the presence therein of uranium (*Ber.*, 1902, xxxv., 531). The thorium oxides from all of these were radio-active. Norwegian gadolinite, orthite, and ytrotitanite free from uranium gave a thorium oxide which neither affected the electro-scope nor the photographic plate (*Ber.*, 1902, xxxv., 533 and 145). The radio-activity of actinium consists primarily of rays or "emanations" simultaneously discovered by Rutherford (*Phil. Mag.*, 1900, xlix., 2; 1903, [6], v., 95) and the Curies, in 1899 (*Rapports au Congrès Int. de Physique*, 1900, iii., 79). The gases emitted by radium and thorium are temporarily radio-active, and may be condensed at -150° and -120° respectively.

The work of Hofmann and Zerban, touching the primary activity of thorium, being questioned by Barker ("Radio-activity of Thorium Minerals," *Am. Journ. Sci.*, 1903, xvi., 164), is upheld by the junior author (Zerban, *Ber.*, 1903, xxxvi., 3911), who determined the presence of from 0.038 to 0.04 per cent of uranous oxide in monazite from Bahia and South Carolina. While the uranium obtained from this sand was quite radio-active, the thorium oxide discharged the electro-scope in two minutes and forty seconds, two minutes and forty-five seconds, and three minutes and five seconds (the instrument without radio-active substance three minutes and twenty-five seconds), and the β -activity affected the photographic plate in twenty-four hours. The reasons for this somewhat detailed account will shortly become apparent.

Brauner (*Proc. Chem. Soc.*, 1901, xvii., 67) reported that the heptahydrated thorium tetrammonium oxalate, which he has used in his excellent method for determining the atomic weight of that element (*Journ. Chem. Soc.*, 1898, lxxiii., 951), hydrolysed on diluting its water solution. By this means he obtained two constituents, which he design-

nated thorium α and thorium β , and ascribed the atomic weights 220 and 260—280 respectively. No subsequent publication on the subject has come from the Prague laboratory so far. At the same time the writer independently reported the results of his observations, extending over some five years, which pointed toward the existence of a new element associated with thorium, and gave it the name *Carolinium* (*Journal. Am. Chem. Soc.*, xxiii., 761). Since that time I have reported in fragments a number of observations in abstract along the same line. They and others are digested in this communication.

While it is unnecessary to recapitulate my first work in the leading paper referred to, it was stated that carolinium was found to be more radio-active than the original thorium. The statement was true for the body in the degree of purity had at that time when examined by the photographic, as reported, and later verified by the electrical method.* On page 761 (*loc. cit.*) it was stated:—"I am not yet ready to assert that the new substance obtained is not the third radio-active body reported by Debierne in pitchblende, actinium, which he states belongs to the iron group." From what follows it is apparent that carolinium and actinium cannot be the same. In fact, the former has little to do with radio-activity, which is the *raison d'être* for the latter.

The elegant researches of Rutherford and Soddy (*Proc. Chem. Soc.*, 1902, xviii., 2) prove that there can be no doubt of the existence of a novel highly radio-active substance with thorium (Thorium X), as it is usually extracted from minerals without consideration of their chemical composition, to which Hofmann and Zerban strenuously direct attention. Such prepared so-called pure salts of thorium contain a radio-active constituent, which may be concentrated chemically by precipitation with ammonia (the filtrate carries Thorium X), and washing the oxide with acid or even water (Rutherford and Soddy, *Phil. Mag.*, 1902, p. 370). The residues obtained by evaporation of the ammoniacal solution in the first case are a thousand times as active as the original, and "are free from thorium, or at most contain only the merest traces, and when re-dissolved in nitric acid do not appear to give any characteristic reaction" (p. 376). Again, the residue from the water washings became 1800 times as active, and after conversion into sulphate, Rutherford and Soddy state:—"No other substance than thorium could be detected by chemical analysis,"† although, of course, the quantity was too small for a minute examination."

Having this in mind, the writer requested Dr. H. S. Miner, chemist to the Welsbach Lighting Company, to save certain ammoniacal washings obtained in the process for the extraction and purification of thorium oxide from monazite sand for the manufacture of the Welsbach gas mantles. The ignited residue obtained from evaporating over 100 litres of this liquor produced a marked effect upon the photographic plate, and showed nearly three times the radio-activity of thorium by the electrical method, using the apparatus of Dolezalek. The radio-activity remained constant through a number of months. The body gave none of the chemical reactions, and did not show a single line of thorium in the arc spectrum made with a large Rowland grating.‡ Dr. Miner is securing an abundance of this material for us, and as soon as practicable this will be thoroughly investigated in our laboratory.

The writer, working with Lichtenhaler,§ has obtained highly radio-active bodies, tested by the photographic method, from thorium, cerium, didymium oxides, and the residual phosphates extracted by ourselves from North Carolina monazite sands. Further, we obtained an extremely active body by precipitating the sulphate solution with hydrogen sulphide, which perhaps would, but not

necessarily, indicate the presence of polonium according to the Curies (*Comptes Rendus*, 1898, cxxvii., 175).

When we consider that barium chloride containing radium may be precipitated by sulphuric acid or silver nitrate, and the filtrate or precipitate obtained thereby, supposedly containing none of that remarkable body, is still radio-active,* we can easily understand how in a mineral or salt a radio-active body, perhaps resembling one of the constituents, clings to various components throughout many chemical manipulations. It having been suggested that uranium might owe its radio-active properties to the presence of small amounts of polonium or radium, Mme. Curie (*Revue Générale des Sciences*, Jan., 1899; M. and Mme. Curie, *Comptes Rendus*, cxxvii., 175) states that such could not be true, and adds, in another paper (M. and Mme. Curie and M. Bémont, *Comptes Rendus*, cxxvii., 1215):—"The property of emitting rays . . . which act on photographic plates is a specific property of uranium and thorium. The physical condition of the metal seems to be of an altogether secondary importance. Uranium and thorium alone are practically active."

It is very foreign from the intention of the writer to be hypercritical of work which stands out so brilliantly, and will remain so for a long time to come, but very painstaking investigations have caused him to face about in this matter, not an unusual condition for scientific truth seekers. The power possessed by the thorium, as usually prepared, of inducing activity, reported by Rutherford and his co-workers (*loc. cit.*), is deeply interesting and supports our thesis. The brilliant French woman states, concerning uranium (*loc. cit.*):—"I have never found any marked difference between the relative activities of the same compound." By analogy one may consistently assume the same for thorium. We have obtained similar compounds of thorium fractions which do differ in their radio-activity, in some cases one being three times as great.

(To be continued).

ON THE DENSITY OF NITROUS OXIDE.†

By Lord RAYLEIGH, O.M., F.R.S.

In the *Proceedings*, 1897, vol. lxii., p. 204 (or "Scientific Papers," vol. iv., p. 350), I have given particulars of weighings of nitrous oxide purified by two distinct methods. In the first procedure, solution in water was employed as a means of separating less soluble impurities, and the result was 3.6356 grms. In the second method a process of fractional distillation was employed. Gas drawn from the liquid so prepared gave 3.6362. These numbers may be taken to represent the corrected weight of the gas which fills the globe at 0° C. and at the pressure of the gauge (at 15"), and they correspond to 2.6276 for oxygen.

Inasmuch as nitrous oxide is heavier than the impurities likely to be contained in it, the second number was the more probable. But as I thought that the first method should also have given a good result, I contented myself with the mean of the two methods, viz., 3.6359, from which I calculated that referred to air (free from H₂O and CO₂) as unity, the density of nitrous oxide was 1.52951.

The corresponding density found by M. Leduc is 1.5301, appreciably higher than mine; and M. Leduc argues that the gas weighed by me must still have contained one or two thousandths of nitrogen ("Recherches sur les Gaz," Paris, 1898). According to him, the weight of the gas contained in my globe should be 3.6374, or 1.5 milligrms. above the mean of the two methods.

Wishing, if possible, to resolve the question thus raised, I have lately resumed these researches, purifying the nitrous oxide with the aid of liquid air kindly placed at my

* This was kindly determined by Dr. Geo. B. Pegram, of the Physics Department of Columbia University.

† Italics theirs.

§ Thesis for degree of Master of Science, unpublished.

* See the works of the Curies, Geisel, Elster and Geitel, Markwald, and others.

† A Paper read before the Royal Society, September, 1904.

disposal by Sir J. Dewar, but I have not succeeded in raising the weight of my gas by more than a fraction of the discrepancy (1·5 milligrams). I have experimented with gas carefully prepared in the laboratory from nitrate of ammonia, but as most of the work related to material specially supplied in an iron bottle, I will limit myself to it.

There are two ways in which the gas may be drawn from the supply. When the valve is upwards, the supply comes from the vaporous portion within the bottle, but when the valve is downwards, from the liquid portion. The latter is the more free from relatively volatile impurities, and accordingly gives the higher weight, and the difference between the two affords an indication of the amount of impurity present. After treatment with caustic alkali and sulphuric acid, the gas is conducted through a tap, which is closed when it is desired to make a vacuum over the frozen mass, and thence over phosphoric anhydride to the globe. For the details of apparatus, &c., reference must be made to former papers. The condensing chamber, which can be immersed in liquid air, is in the form of a vertical tube 2½ c.m. in diameter and 22 c.m. long, closed below and above, connected laterally to the main channel.

The first experiment on July 13 was upon gas from the top of the bottle as supplied, and without treatment by liquid air, with the view of finding out the worst. The weight was 3·605, about 35 milligrams too light. The stock of material was then purified, much as in 1896. For this purpose the bottle was cooled in ice and salt,* and allowed during about one hour to blow off half its contents, being subjected to violent shaking at frequent intervals. Subsequently three weighings were carried out with gas drawn from the bottom, but without treatment by liquid air. The results stand:—

July 18	3·6368
July 20	3·6360
July 25	3·6362
Mean	3·63633

Next followed experiments in which gas, still drawn from the bottom of the bottle, was further purified by condensation with liquid air. The gas, arriving in a regular stream, was solidified in the condensing chamber. When it was judged that a sufficiency had been collected, the tap behind was turned and a high vacuum established over the solid mass with the aid of the Töpler pump. The pump would then be cut off, and the gas allowed to evaporate and accumulate in the globe. A re-application of liquid air caused the gas to desert the globe for the condensing chamber, until in a surprisingly short time a vacuum was re-established. Little or nothing could now be drawn off by the pump, and it was thought that a distinct difference could be perceived between the first and second operations, indicating that in the first condensation a little impurity remained gaseous. If desired, the condensation could be repeated a third time. On one occasion (August 7) the condensed gas was allowed to liquefy, for which purpose the pressure must rise to not far short of atmospheric, and to blow off part of its contents:—

August 1	3·6363
August 3	3·6367
August 7	3·6366
Mean	3·63653

The treatment with liquid air raised the weight by only 0·2 milligram., but the improvement is probably real. That the stock in the bottle still contained appreciable impurity is indicated by a weighing on August 13, in which without liquid air the gas was drawn from the top of the bottle. There appeared—

August 13	3·6354
-------------------	--------

about 1 milligram. short of the proper weight.

* The lower the temperature below the critical-point, the more effective is this procedure likely to be.

It will be seen that the result without liquid air is almost identical with that found by the same method in 1896, and that the further purification by means of liquid air raises the weight only to 3·6365. I find it difficult to believe that so purified the gas still contains appreciable quantities of nitrogen.

The corresponding weight of air being 2·3772 (*Proc. Roy. Soc.*, 1893, vol. liii., p. 134; "Scientific Papers," vol. iv., p. 47), we find that, referred to air as unity, the density of nitrous oxide is—

$$\frac{3·6365}{2·3772} = 1·5297.$$

Again, if oxygen be taken as 16, the density of nitrous oxide will be—

$$\frac{3·6365 \times 16}{2·6276} = 22·143.$$

The excess above 22 is doubtless principally due to the departure of nitrous oxide from Boyle's law between atmospheric pressure and a condition of great rarefaction. I hope shortly to be in a position to apply the connection which will allow us to infer what is the ratio of molecular weights according to Avogadro's rule.

AN IMPROVED FORM OF KIPP'S APPARATUS.

By R. J. FRISWELL, F.I.C., F.C.S.

EVERYONE who has to work with the above well-known apparatus has had occasion to notice its many defects. Among these the most serious are:—

- (1) Rapid degeneration of the acid liquids and early appearance of sluggishness in the reaction.
- (2) Wastefulness of the acids.
- (3) Necessity for frequent re-charging, which, apart from the waste involved, is an unpleasant operation.

Having occasion to make constant use of several Kipp's for some months past, I was led to study the apparatus with the object of improving it, if possible, in these directions, and as a result have devised the modification here described, in which all the above objections are reduced to a minimum, and, in fact, practically abolished.

The form of the new apparatus is shown in the accompanying drawing.

1, 2, and 3 are the usual three bulbs of the ordinary Kipp's apparatus. At A in bulb 1 is shown the upper end of a tube ground in to the neck and passing down to the

bottom of the lowest bulb. This tube is very slightly flared at the top, which should be situate at about three-fourths of the diameter of the bulb from its lowest part. The bulb *r* is separate from the remainder of the apparatus, being ground in to the neck of bulb 2 as usual.

a is a neck with cock and tube serving to draw off contents of bulb 1. *c* is the usual neck and cock for outlet of gas from bulb 2. *d* is the neck with ground stopper in bulb 3; (with this form of apparatus this is not really necessary).

The tube *a* is shown in full outside the apparatus on the right hand side.

Before use the tube *a* must be securely fastened into its seating in the uppermost bulb 1. To do this gently warm the ground part of the tube at *e*, and of the bulb, smear on to the ground part of the tube a very little good fresh marine glue. Put it into its place and firmly press it home with a turning movement. Be careful that none of the marine glue gets on to the outer ground neck of bulb 1.

The apparatus may now be put together.

To use it charge the centre bulb 2 with the marble, zinc, or ferrous sulphide as usual, taking care that the material is free from dust. N.B.—A light layer of asbestos or glass-wool round the tube before putting in the material is advantageous if small fragments are to be used.

Now pour down the centre tube, by means of a funnel, sufficient strong calcium chloride, zinc sulphate, or ferrous chloride solution to fill up the lowest bulb nearly to the top. A space of half an inch between the top of this liquid and the lowest fragments in the centre bulb should be left at the least.

Now pour in the acid until the uppermost bulb is so filled that the acid stands an inch or so above the flared lip of the standing tube *a*.

It is, of course, necessary that all the cocks should be closed and the stoppers secured in their places.

The apparatus is now ready for work.

The following is the method of use:—Open the gas-cock slightly so as to allow the acid to descend very slowly. If the glass-cock works stiffly it is better not to depend on it, but to slip a rubber tube with a screw pinch-cock over the nose of the glass-cock. Close the pinch-cock, open the glass-cock, and then slowly open the screw pinch-cock.

If these directions are accurately followed the acid will descend the centre tube, and, rising through and floating on the strong salt solution in the bottom of the apparatus, reach the centre bulb at nearly full strength, and when the gas pressure rises the exhausted liquor will be slowly and steadily pressed back to the upper reservoir.

When the gas-cock is closed this action will be very noticeable. The liquids having changed places, the strong salt solution forced back to replace the acid will be seen falling over the lip of the flared tube in the upper reservoir through the stronger acid therein.

When an accumulation of this denser liquid in the upper reservoir takes place to such an extent that its level approaches the upper part of the standing tube, it can be drawn off by the cock *b*, and fresh acid carefully poured in by means of a funnel whose tube is long enough to enter about half an inch into the standing tube *a*.

If these instructions are carefully followed, the contents of the lowest part of the apparatus need never be disturbed or removed.

When the gas generating material in the centre is exhausted, or needs renewal, draw off from the cock *b* till the liquid is below the lip of the standing tube *a*; now insert a long stemmed 50 or 100 c.c. pipette into the standing tube and draw out its contents for 5 or 6 inches of its length, or to about the middle of the centre bulb 2.

The gas-cock and tube of this may now be removed, the new material put in, cock and tube replaced, upper reservoir re-charged with acid, and the apparatus at regular work in the course of a few minutes.

It is, perhaps, needless to point out that, as the economical action depends on the different densities of the fresh and the exhausted acids, a permanent place

should be found in the laboratory for the apparatus, which should be moved as little as possible, so as not to shake up and mix the strata of liquors in the upper reservoir.

In this respect it requires to be treated in exactly the opposite way to the old form of Kipp, in which, as the liquids were returned to the reservoir in the order of their entry into the gas generator, the liquid reaching the gas generating materials is always that most saturated, the freshest acid lying on the top, and requiring the liquid in the upper bulb to be well swung round in order to strengthen the exhausted liquor in the lower part of it, otherwise sluggish action is even sooner manifested than it would otherwise be.

As an example of the separation of the strengths, the following experiment may be given:—

The apparatus charged with exhausted liquor at the bottom and fresh acid in top bulb. The gas was shut off after some time, and a considerable quantity of the exhausted liquor forced up the tube *a*, and was seen to fall down through the acid in No. 1. A sample was drawn off; its gravity was 1.333, free HCl 6.86 grms. per litre. Some liquor was now drawn from just below the surface of the liquid in bulb No. 1 with a pipette. Its gravity was 1.276, and the HCl was found to be 26.02 grms. per litre.

It is, perhaps, needless to point out that scraps of marble, &c., must on no account be allowed to fall into the lowest bulb, or the effervescence will mix the strata therein.

MESOXALIC SEMIALDEHYDE.*

By HENRY J. HORSTMAN FENTON, F.R.S.

MESOXALIC semialdehyde ($\text{COOH}-\text{CO}-\text{CHO}$), it has been previously shown (Fenton and Ryffel, *Trans. Chem. Soc.*, 1902), can be obtained by the oxidation of dihydroxymaleic acid with ferric salts at about 40° . This method is not altogether satisfactory, owing to the difficulty of removing the iron salts, and it is now found that the oxidation may advantageously be effected by means of mercuric chloride. In this case the mercury separates almost quantitatively as calomel, and any traces remaining may be removed by hydrogen sulphide. The properties of this semialdehyde are being further studied, and appear to be of considerable interest. It is evident that the aldehyde hydrate, $\text{COOH}-\text{CO}-\text{CH}(\text{OH})_2$, may be regarded as a tautomeric form of the missing trihydroxyacrylic acid, $\text{COOH}-\text{C}(\text{OH})=\text{C}(\text{OH})_2$, and the latter should, by condensation with two molecules of urea, yield uric acid.

If a solution of mesoxalic semialdehyde is mixed with urea and heated, together with dilute hydrochloric acid, a large yield of a very sparingly soluble crystalline substance is obtained which, by its properties and composition, proves to be *glycoluril*, $\text{C}_4\text{H}_6\text{N}_4\text{O}_2$. This compound was originally obtained by reduction of allantoin, and afterwards from glyoxal and urea.

It is evident, therefore, that a molecule of carbon dioxide splits off in the reaction above described; later experiments appear to indicate, however, that by modifying the conditions this loss may be prevented, in which case it is hoped that uric acid itself may be obtained.

Although the properties of glycoluril have been carefully studied by various authors, the following very striking colour-reaction appears to have been overlooked:—The substance is evaporated to dryness with strong nitric acid on a water-bath, and the white residue dissolved in caustic soda; a faint blue violet colour here results, and now, on addition of sodium hypochlorite, a very brilliant purple colour is obtained.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

SOME OBSERVATIONS

ON THE GROUPING OF THE LINES IN THE SPECTRUM OF SILICON THROUGH THE EFFECT OF SELF-INDUCTION, AND THEIR PRESENCE IN STELLAR SPECTRA.*

By M. le Comte A. DE GRAMONT, D.Sc.

In a short note† presented to the meeting of the British Association at Southampton (1903) I gave the first results of my research on the comparison of the lines of silicon which, under the action of self-induction, remain or disappear, and the corresponding lines in stellar spectra. After having photographed the entire spectrum as far as λ 2930 with a spectrograph in which the optical system was entirely of quartz, and having repeated the middle portion with an Iceland spar prism, I made a special examination of the portion susceptible of astronomical comparison (given herewith) by means of two prisms of heavy flint glass and with an achromatic objective of 45 c.m. focal length. The negatives obtained had on their upper portions the ordinary condensed spark spectrum of silicon, obtained by means of a coil giving a 15 c.m. spark and a condenser of 0.005 microfarads capacity. In coincidence with this spectrum were photographed, one under the other, the spectra which resulted from the action of self-induction varying from 0.0002 to 0.03 henry. The wave-lengths were measured by comparison with those of a lead-cadmium alloy, and calculated by large scale curves or by means of an interpolation formula.

I would add here to my note of last year the results I have obtained since, and their comparison with the grouping Sir Norman Lockyer submitted the same lines to, by arranging them according to temperatures supposed to be increasing, in which Group IV. would correspond to the maximum temperature:—

Thermic groups according to Lockyer.	Groups classified according to the effect of self-induction.	
IV. { 4089.1 4096.9 4116.4	{ (O?) 4089.3 (N?) 4097.3 (N?) 4116.5 (N?) 4103.5	{ Disappear with a very slight self-induction (0.00008 H.) at the same time as the air spectrum.
III. { 4552.8 4568.0 4574.9	{ δ { 4552.3 4597.5 4574.6 3807.5 3796.0 3791.5 3794.5 3087.2 4131.0 4128.2	{ Become much weaker with the above self-induction, and disappear with a mean self-induction of 0.0006 H.
II. { 4131.1 4128.1 5042.0 5057.0 3853.9 3856.1 3862.7 3905.8 4103.2	{ ϵ { 3854.2 3856.1 3862.5 3905.7 γ { 5044.0 5058.7	{ The latter disappear with a self-induction of 0.006 H. { Resist the action of maximum self-induction, 0.03 H.

The lines of Group IV., which, according to Lockyer, indicate an excessive temperature, have, on my plates, always accompanied the air lines, and disappear with them. The lines coincide with the lines of oxygen and nitrogen, the presence of which has been detected in several stars in Orion and in θ Crucis (MacClean, "Spectra of Southern Stars," 1898). Therefore I am of the opinion that Group IV. does not belong to silicon. The line 4103.5

* Read before the British Association (Section B), Cambridge Meeting, 1904.

† To correct a misprint for a yellow line, in place of β 3879 read β 5079; compare with my previous work on silicon (*Comptes Rendus*, January 25, 1897).

does not appear to me to correspond with the line, 4103.1, found by Rowland in the arc spectrum of silicon and in the ordinary solar spectrum (but not at all in the spectrum of an eclipse); I believe it, also, is due to air.

Group III. might be completed by the triplet, Si η , which accompanies Si δ in ϵ *Canis majoris* and in several stars in Orion. The doublet Si θ will be detected perhaps some day with a reflector and a quartz prism. The two green lines, Si γ , should not be included in this group, as they absolutely resist the strongest self-induction I have been able to use; they might be considered as low temperature lines, and be placed in Group I. with the line Si ζ , 3905.7, common to the arc and the spark, and which belongs to the ordinary solar-spectrum, as well as to the "flash-spectrum" of eclipses (Evershed).

The triplet ζ_2 and the doublet ϵ in the violet appear to be closely associated and concomitant in the spectra of stars, as well as in regard to self-induction; thus they remain in the same group.

From what has preceded, and considering, on the one hand, the lines that are made successively to disappear by self-induction from the spark spectrum, and on the other hand the distribution of the corresponding lines in stellar spectra, we may draw the following conclusions:—

1. Only the stars of Secchi's first class, those containing hydrogen and helium, show the lines of silicon suppressed by self-induction, the properly called helium stars, like those in Orion or ϵ *Canis majoris*, show the lines Si δ , Si η very strongly, and they disappear the first. The more specially hydrogen stars like Sirius, and those which approach the solar type, like Procyon, show more particularly the lines Si ϵ and Si ζ_2 ; the latter disappear on increasing the self-induction.

Deneb (α Cygni), which appears to be in an intermediate stage, shows simultaneously the characteristic lines of both these categories of stars.

2. The stars of the second class (solar type) showing the special lines of the arc, comprise Si ζ , common to the arc and the spark. It would be interesting to try whether some of the stars of this class would not also give the persistent doublets Si α in the red (6320—6342) and Si γ in the green. These two latter doublets, Si α and Si γ , are the most distinct and the most sensitive for analytical chemistry.

3. The stars with band spectra, the third and fourth classes, with not very high temperatures, have not yet shown any silicon lines.

Thus we see that the distribution of the silicon lines in the stars appears to be in accordance with the usual classification of these latter.

In the most refrangible portion of the spectrum, and with no astronomical correspondence, the strong line 2542 disappears with a self-induction of about 0.006 H. The other lines, especially the very characteristic group of six lines (2529 to 2507), having an extreme sensitiveness in regard to chemical analysis as pointed out by Mr. Hartley (*Proc. Roy. Soc.*, March 25, 1901), in the case of solutions, and the group 2217 to 2209, resist the maximum self-induction of 0.03 H without apparent diminution. Finally, I have found that the extreme line 1930.0 does not belong to silicon but to aluminium. In this research I have made use of silicon crystallised in small octahedra, and in plates; also silicate of sodium fused in the blowpipe on platinum wires. As I have already shown, the effects of self-induction are the same with solid bodies and with fused salts submitted to the action of the spark.

NOTE.—In 1895, the CHEMICAL NEWS (vol. lxxii., p. 103) contained the summary of a paper by M. de Gramont presented to the Académie des Sciences, Paris, on the "Direct Spectral Analysis of Minerals." The paper which appeared in our last issue (p. 140) is a continuation of this work.

ERRATA.—P. 140, col. 2, line 18 from bottom, for "scale" read "grating." Last line of Table, col. 2, for "3495.4" read "3497.4."

ON THE BEARING OF THE
COLOUR PHENOMENA PRESENTED BY
RADIUM COMPOUNDS.*

By WILLIAM ACKROYD.

MADAME CURIE early observed that radium salts are white like barium salts when first prepared, but that they gradually become coloured ("Thesis on Radio-active Substances," p. 30; London, CHEMICAL NEWS Office). I have associated this colour-change with the reception of external radiant energy and the consequent increase of radio-activity (*Lancet*, November 21, 1903, p. 1464). What I take to be confirmation of this view has been obtained in following the history of a radium bromide tube. The salt was nearly white when purchased, and in a month or two it became tawny-yellow or orange; its powers of absorption had visibly increased, and its power of exciting fluorescence in barium platino-cyanide was concurrently quadrupled. These facts may be thus diagrammatically represented:—

Colour-change and increase of absorption.

White, yellow, orange, tawny-orange.

Increase of radio-activity.

This readiness on the part of radium compounds to become coloured under the influence of external radiations may be regarded as an effort to conform to the constitutive-colour law (*B.A. Report*, 1903, and *CHEMICAL NEWS*, 1903, lxxxviii., 217); moreover, it is highly probable that the colour-change is effected by a minimum expenditure of energy, as in the case of other end members of vertical groups of the periodic classification of the elements. This tendency I have experimentally demonstrated in the case of chlorides of alkali metals (*Journ. Chem. Soc.*, 1904, lxxxv., 815).

But while we may regard this colour-change as being slowly effected by external radiations, the comparatively sudden application of sensible heat has a very different effect. In July, 1903, I strongly heated tawny-orange radium bromide, expecting to see it change in this order—red, brown, black, like mercuric oxide and other colour-changing bodies. Instead, the seething substance reverted at once to white. The colour behaviour of the radium bromide when heated is evidently anomalous like some other compounds of extreme members of vertical periodic groups; as, for example, mercuric iodide. Its powers of absorption are visibly lessened, and, as is now well known, the radio-active properties of the residue are also lessened. The increase in the radio-activity of the expelled emanation is another phenomenon, and probably the joint product of radium rays and heat. Analogous effects are produced by radium rays and heat on halides of the alkali metals (*Journ. Chem. Soc.*, 1904, lxxxv., 816). Cesium chloride was exposed to radium rays for half-an-hour at 16° C.; the radium compound was then removed, and the temperature of the cesium salt was raised to 37° C. The phosphorescence was now markedly increased by the rise of temperature. May we not, then, suppose that the bodies occluded in radium compounds have radio-activity conferred on them while there, and that this radio-activity is increased by the heat which is necessary for their expulsion?

Crucial tests of the validity of this energy-transformation theory appear to be presented in the following additional facts. If water be admitted to the contents of a radium bromide tube its phosphorescence is practically undiminished (*CHEMICAL NEWS*, 1903, lxxxviii., 206). Rutherford has studied the matter quantitatively, and finds that solution of a solid radium compound to a thousand times its volume does not appreciably affect its radio-activity, which he has attempted to explain on the atomic disintegration theory

(*Nature*, 1904, lxxx., 222). I have, however, pointed out that under such conditions there is approximate constancy of absorption of external radiant energy which ought to result in a like constancy of radio-activity (*Nature*, 1904, lxxx., 295).

Again, the 60 per cent difference of heat emission in the Curie-Laborde and Curie-Dewar estimations appears to receive a rational explanation from this point of view. At normal temperature the output of heat from a radium compound was found to be of the order of 100 calories per gm. of radium per hour, while at the temperature of boiling oxygen it was only 38 calories. Now a colour-changing substance, whilst passing from normal temperature towards the region of absolute zero, becomes white, or, in other words, lessens its capability of absorbing external radiant energy; and it is now suggested that probably to this cause is to be attributed the low numbers obtained by Professors Curie and Sir J. Dewar at the temperature of boiling oxygen.

A CONTRIBUTION TO THE THEORIES OF
OSMOSIS, SOLUBILITY, AND NARCOSIS.*

By Professor I. TRAUBE, Berlin.

UPON the results of a series of investigations, by plasmolytic methods, of the velocity of the osmosis of chemical compounds into the protoplast, Overton bases the theory that the magnitude of the distribution coefficient between such substances as fat, cholesterolins, and lecithins on the one hand, and water on the other, determines the velocity of the osmosis. He assumes that, in the first instance, a dissolution takes place in the fatty substance of the membrane at a velocity proportional to this coefficient, and that thereupon the substance passes on from the membrane to the interior of the cell. Moreover, Overton, and, independently, Hans Meyer, point out that all the reliable narcotics, anesthetics, and antipyretics belong to the class of rapidly diffusing substances, and hence they deduce the theory that the efficacy of a narcotic depends principally on its lipid solubility. These theories, however, in so far as they concern osmotic velocity, are erroneous. The author's investigations on the constants of capillarity of substances, especially solutions, have led to the result that the greater the osmotic velocity of a substance soluble in water the more this substance reduces the constant of capillarity of water, whilst substances which cannot penetrate membranes (with regard to which the membranes are impermeable) raise this constant. Among hundreds of compounds examined plasmolytically by Overton, and as to capillarity by the author, there is not one case in which capillary and osmotic phenomena do not correspond. It is evident that osmotic velocity and surface tension run parallel. Hence the difference of the surface tensions—or of the internal pressures—is the motive force in osmotic phenomena; it is to this difference that osmotic pressure is due.

The theory here stated leads to a new conception of the phenomena of diffusion and solution. Suppose that an aqueous solution of a salt be brought in contact with pure water. According to the prevalent theory the salt particles or the ions, in virtue of their "osmotic pressure," migrate into the pure solvent; but according to the author's view it is the pure solvent which, in virtue of its low surface tension, migrates into the salt solution. Again, let two liquids capable of dissolving in each other be brought in contact, or let a solid be in contact with a pure solvent, then the solution tension will depend chiefly on the difference between the surface tensions. From this we may expect that when a liquid or a solid substance dissolves in a solvent, the surface tension of the solution will never fall below that of the dissolving substance, and if the surface

* Read before the British Association (Section B), Cambridge Meeting, 1904.

* Abstract of a Paper read before the British Association, Section B, Cambridge Meeting, 1904.

tensions of solution and dissolving substance be equal, the solution will be saturated. The surface tension of a saturated solution is *in maximo* as low as that of the dissolved substance; consequently, the latter value determines the shape of the curve of the surface tension of solutions.

From the author's former investigations he deduced the law that equal equivalents of substances belonging to homologous series, which exercise a strong influence on capillarity (ordinary alcohols, fatty acids, esters, &c.), lower the capillary height of water in the proportion $1:3:3^2:3^3$ If 3 molecules of methyl alcohol reduce the surface tension of water as much as 1 molecule of ethyl alcohol, the conclusion is justified that the tendency to enlarge the surface of water is three times less in the case of methyl alcohol than in the case of its nearest homologue. Hence the tendency of methyl alcohol to separate from the solution may be considered as three times less than the corresponding tendency of ethyl alcohol; or, in other words, the solution tension of substances belonging to homologous series, which exercise a strong influence on capillarity, increases with increasing molecular weight in the proportion $1:3:3^2:3^3$

If a layer of a liquid insoluble in water, say, benzene, be placed upon an aqueous solution of different alcohols, esters, &c., the amount of dissolved substance of which this liquid will deprive the water will be greater in exact proportion as the solution tension is less. Distribution coefficients and solution tension—are therefore proportional magnitudes in first approximation.

Thus Overton's theory is erroneous in so far as it represents penetration into the cell as depending on the degree of lipid solubility; for dissolution of the dissolved substance in the lipids certainly does not take place. The motive force is the surface tension. Overton and Meyer have pointed out that the efficacious narcotics, anaesthetics, and antipyretics all belong to those compounds which penetrate thin membranes rapidly. Rapid penetration into the cell seems to be the most essential condition for enabling a narcotic to exercise its effect on the interior of certain cells. Thus narcotics which differ materially in their chemical composition may possibly exercise their action in different cells, and this action may vary considerably even when exerted on one and the same species of cell. But if narcotising substances of the same homologous series, such as the ordinary alcohols or esters, be considered, we are brought to the conclusions that the cells acted on are all of the same species, that the action in the interior of the cell only differs in degree, and finally that this difference depends essentially and solely on the velocity with which the homologous substances penetrate into the cells. Now this velocity has been shown to be proportional to the depression of the surface tension of water by the dissolved substances, and hence we cannot but conclude that the same law holds good for the narcotic action of homologous substances as has been proved to be valid for surface tension, and approximately so for the distribution coefficients.

ACTION OF H_2O_2 ON CARBOHYDRATES IN THE PRESENCE OF FERROUS SULPHATE.*

By R. S. MORRELL and A. E. BELLARS.

This investigation has been in progress for nearly six years in conjunction with Mr. J. M. Crofts, and lately with Mr. Bellars.

The production of dihydroxymaleic acid from tartaric acid by Fenton in 1894, showed that this oxidising agent exercised a peculiar action on secondary alcohol (CHOH) groupings. Cross and Bevan, in 1898, pointed out that

carbohydrates, which were unacted upon by hydrogen peroxide at the ordinary temperature, were very readily attacked if a little ferrous sulphate was added, and amongst the products was a substance which reacted strongly with phenylhydrazine at the ordinary temperature. By agreement with these three investigators, we have examined the oxidation products of a series of pentoses, hexoses, and bioses, and have found that the substance which reacts with phenylhydrazine at the ordinary temperature is of the nature of an osone. E. Fisher, in 1889, pointed out that osones are not fermented by yeast, and in our experiments, after fermenting off the sugar unacted upon by the hydrogen peroxide, the solution still reacts with phenylhydrazine at the ordinary temperature to give an osazone.

Glucosone has not been obtained crystalline, but only in the form of a syrup or amorphous solid. On reduction with zinc dust and acetic acid, it yields a levorotatory solution, which reacts with phenylhydrazine to give an osazone melting at 206° .

The yield of the osazone, obtainable at the ordinary temperature, depends upon the nature of the sugar. Fructose, glucose, mannose, and cane-sugar give the best yields.

Rhamnose is next in order; arabinose gives a small quantity only, while galactose does not yield a true osazone. Amongst the bioses, lactose gives none and maltose only a small amount, and the quantity does not seem less even after fermentation.

During the last year, investigations on the change in optical activity during the oxidation have been undertaken, and the results are of some interest. In the case of the hexoses, the fall in angle is fairly proportional to the amount of peroxide added up to 1 grm. molecule of H_2O_2 .

Glucose, fructose, and galactose were the hexoses examined. In the two former cases, the diminution in optical activity was practically the same, but in galactose the drop is much greater, and it was found that galactose gave a ketoacid of the hexose rather than an osone. The diminution in optical activity on oxidation in the case of the bioses seems to be connected with their tendency to be hydrolysed. Maltose shows the smallest drop in angle, and is hydrolysed with much greater difficulty than cane-sugar.

Lactose lies between maltose and cane-sugar, and this agrees with its power of being hydrolysed. Cane-sugar shows a drop in angle exactly the same as glucose and fructose.

Two pentoses have been investigated, arabinose and the methyl pentose rhamnose. Arabinose lies between glucose and galactose, but rhamnose shows an extraordinary behaviour; the original sugar is dextrorotatory, but on oxidation it becomes levorotatory, which is partly due to the osone, and partly to an acid which is not rhamnonic acid.

The acids formed are by no means easy to identify, for the yield of the lead salts is very small. The dibasic acid formed, which has been identified in the case of glucose, fructose, and rhamnose, is oxalic acid precipitated by normal lead acetate; the monobasic acids, which have been obtained from fructose and glucose by the use of four atoms of oxygen, are glyoxylic, glycollic, and trioxibutyric acids, but in addition there is, in the case of all the sugars investigated, evidence of a keto acid other than glyoxylic acid brought down partially by normal lead acetate, and completely by basic lead acetate.

In connection with the action of bases on the osones, it was found that an alcoholic solution of an osone reacted with guanidine to give a white semicrystalline substance, which contained 14.87 per cent $CN_2H_5 \cdot C_6H_{10}O_6(C_2H_5OH)$ requires 14.64. We have been unable to find any reference to guanidine compounds of sugars, and it was thought advisable to prepare a series of them and to investigate their properties. Glucose, fructose, galactose, arabinose, rhamnose, and maltose have been examined, and their compounds with guanidine have been investigated. These compounds, in the case of those with glucose and maltose,

* Read before the British Association (Section B), Cambridge Meeting, 1904.

are addition products of 3 molecules of the sugar with 2 of guanidine. In water they are strongly alkaline, and by dilute acids, N/10 HCl and oxalic acid, the guanidine is completely and quantitatively removed.

They are apparently not hydrolysed immediately by water, for their optical activity is much less than that of the parent sugar. In the case of glucose, the specific rotation $(\alpha)_D = +29.8^\circ$, and after five days has become $(\alpha)_D = -5.7^\circ$. An aqueous solution of the substance neutralised by HCl gave the rotation for free glucose. This behaviour is similar to that of sugars with alkalis referred to by Löbry de Bruyn.

A NEW THEORY OF THE PERIODIC LAW.*

By G. J. STOKES.

VARIOUS mathematical interpretations have been proposed of the Periodic Law. The following is not a mathematical but a logical interpretation of the law, and enables us to arrive at chemical results deductively. It is the chemical application of a more general method applicable to mathematics and physics.

It has been shown by De Morgan (*Cambridge Trans.*) that the relations between any two things x and y , if we take account not only of x and y but also of not- x and not- y , admit of seven, and only seven, varieties.

These relations were termed by him:—(1) Identical, (2) sub-identical, (3) super-identical, (4) complete particular, (5) super-contrary, (6) sub-contrary, (7) contrary.

The following diagrams taken from Mr. Keynes's "Formal Logic," Third Edition, illustrates these relations in the order given. The notation is slightly changed.

I have substituted, to express the negative, small letters instead of dots for the sake of clearness.

Shortly after the appearance of the Third Edition of Mr. Keynes's "Logic" in 1894, I applied these diagrams to the first seven elements arranged according to their order in the periodic classification: (1) representing Li, (2) Be, (3) B, (4) C, (5) N, (6) O, (7) F. I then, in accordance with a principle underlying the whole relation of logical forms to nature, considered the diagrams to combine in such a way that the large letters entered into combination with the small, so that in each case a pair of letters combine simultaneously. Each separate compartment of a diagram has an affinity for, and enters into, combination with that compartment, or those phases of two compartments of another diagram, or of its own diagram, which are most unlike. There results a scheme of arrangements conformable to and parallel with the chemical facts, so that these might have been predicted beforehand. It gives the forms of combination, the affinities, tells what bonds are satisfied, and how many left unsatisfied. It enables us to predict stability or instability of the compound, and sometimes physical features, such as hardness, *e.g.*, the diagram for carbon gives three forms, one of which, involving combination in every available way, I take to be the diamond.

I have endeavoured to extend it to succeeding series in the periodic arrangement of the elements. The conclusion I have reached is that the same principle applies to elements of higher atomic weight, that the difference is quantitative or numerical, and would involve duplication, triplication, &c., of the diagrams. They then become so complicated that they cannot be read easily. With regard to those groups falling into the eighth class of the elements, as Fe, Co, &c., I have not yet succeeded in finding a diagrammatic interpretation.

The form of diagrams given above, while useful in logic, are not those best adapted for physical investigations. I was therefore early led to try diagrams in tri-dimensional space. This of itself suggested the application to crystals.

If, as some crystallographers recognise, there are seven systems, this might help to explain the connection between chemical properties and crystalline form.

If the theory here put forward is true it may be asked in what direction does it point? At first sight it may appear opposed to the most recent ideas of physical chemistry.

It is impossible, however, not to recognise the close analogy between the positive and minus signs of the diagrams and positive and negative electricity. It is best to confine oneself to the most general and abstract statement, that the variety of the members of the periodic series depends on the varying relation of two principles towards each other, which are capable of every one of the relations of identity, exclusion, &c., which are logically possible between them.

NOTICES OF BOOKS.

Electro-chemistry. Part I. By R. A. LEHFELDT, D.Sc. London, New York, and Bombay: Longmans, Green, and Co. 1904.

THIS book, which is one of the series of text-books of physical chemistry edited by Sir William Ramsay, deals with the general theory of electro-chemistry, and includes a chapter on the "Relation of Chemical Constitution to Conductivity," written by T. S. Moore, B.A., B.Sc., which will be found of great interest by students of organic

* Read before the British Association (Section B), Cambridge Meeting, 1904.

chemistry, in which region new results of importance are being obtained almost every day by the application of electrical methods. This chapter, which is limited to the study of aqueous solutions, gives a very complete and succinct account of the subject. The rest of the book is divided into two chapters on the "Mechanism of Conduction in Electrolytes" and the "Theory of Chemi-electromotive Force" respectively. The first of these subjects is treated very fully, but the author does not succeed in making it interesting, so that the student will find a good deal of the chapter dull and troublesome reading. This is indeed the chief blemish on the whole book, though it is less to be remarked in the pages on chemi-electromotive force, which include a description of the construction, &c., of normal cells. The student who works through this book should have a very good knowledge of the chief facts and theories of electro-chemistry, but it seems hardly probable that he would be inspired with enthusiasm for the subject.

An Introduction to the Study of Spectrum Analysis. By W. MARSHALL WATTS, D.Sc. (Lond.), B.Sc. (Vict.), F.I.C. London, New York, and Bombay: Longmans, Green, and Co. 1904.

The author of this book has endeavoured to produce a work which shall be of service to the beginner, and at the same time give an account of the very latest developments of the subject, and these two aims have somewhat militated against one another. In accordance with the first, the most elementary optical principles and facts are described and explained very simply, even the trigonometrical ratios being defined, so that very few calls are made upon the readers' previous knowledge of elementary physics and mathematics. The chapters on the means adopted for the production of spectra are followed by freely illustrated descriptions of the spectra of stars and nebulae, and of the sun, the discovery of new stars, and the spectra of comets, and a discussion of the relationships between the lines of the spectra of allied elements and between the different lines of a spectrum, which is very lucidly treated. Thus the work will be seen to cover a fairly wide ground on the whole very successfully. It includes a catalogue of spectra, and in an appendix a paper by Sir William and Lady Huggins on the "Relative Behaviour of the H and K Lines of the Spectrum of Calcium," and a preliminary note by the same authors on "Some Modifications of the Magnesium Line at λ_{4481} under Different Laboratory Conditions of the Spark Discharge."

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 7, August 16, 1904.

A Crystalline Compound of Lead Acetate and Lead Sulphate, $2\text{S}_2\text{O}_3\text{Pb}(\text{CH}_3\text{—CO}_2)_2\text{Pb}$.—P. Lemout. — When a dilute solution of sodium thiosulphate is added to a solution of lead acetate, a white precipitate of lead thiosulphate is formed. If acetic acid is then added, this precipitate disappears more or less completely according to the concentration of the original mixture. If the conditions are favourable for complete solution of the precipitate, and the whole left for a little time, a compound in the form of very heavy fine white needles separates out. These are sometimes 3 or 4 m.m. long. An analysis of this compound proves it to have the formula $2\text{S}_2\text{O}_3\text{Pb}(\text{CH}_3\text{—CO}_2)_2\text{Pb}$.

Alloys of Zinc and Magnesium.—O. Boudouard.—The author prepares the compound Zn_2Mg by acting on a

mixture of zinc and magnesium (80 per cent Zn to 20 per cent Mg) with a 0.3 per cent solution of hydrochloric acid. When left in contact for several days the metal disintegrates and gives a metallic powder, of which the composition corresponds to the compound Zn_2Mg . To isolate the compound ZnMg_4 , a mixture of zinc and magnesium (70 per cent Mg, 30 per cent Zn) is treated with a 0.5 per cent solution of ammonium hydrochlorate and heated for several hours. A metallic powder corresponding to the above formula is deposited. Without heat this latter reaction takes a very much longer time.

Constitution and Properties of Chromium Steels.—Léon Guillet.—The author examines by micrography and mechanical methods two series of chromium steels: one containing very little carbon and the other about 0.850 per cent of carbon. In each series the chromium increases from 0 to 40 per cent. His experiments lead him to subdivide chromium steels into four classes. From an industrial point of view, steels containing a double carbide should be rejected; they are too fragile. The martensitic steels, owing to their very great hardness, can only be employed in particular cases. Of all the martensites which the author examined, those containing chromium are the hardest. This fact explains the use of chromium steels for certain tools, such as files.

Evolution of Structure in Metals.—G. Cartaud.—The metals examined by the author are the most fusible, such as lead, tin, or zinc; his chief experiments as to the structure of the metal being performed on lead.

MISCELLANEOUS.

Photo-Engraving and Lithography.—We have much pleasure in drawing attention to the prospectus of the London County Council School of Photo-Engraving and Lithography (6, Bolt Court, Fleet Street, E.C.), the work of which is particularly identified with the printing craft. Principal: A. J. Newton. The Tenth Session will commence on Monday, September 26th. The School is open to those who are genuinely engaged in business in any branch of the photo-mechanical, photographic, designing, illustrative, lithographic, engraving, and printing crafts, and no provision whatever is made for amateurs. The courses of practical instruction are arranged to suit the following craftsmen:—

Photo-Engravers.—Line and screen negative making, etching, proving, tricolour work. Photogravure and preparation of originals for reproduction.

Photo-Lithographers.—Negative making, photo-lithography, colotype (plate preparation, press, and machine work), combinations of lithography and colotype.

Photographers.—Line and continuous tone negative making, printing, enlarging, transparency making.

Lithographers.—Lithography, map and plan drawing, transfer writing, drawing, design, lettering, photo-lithography.

Designers.—Design, drawing, lithography.

Draughtsmen.—Drawing, design, lettering. Pictorial composition.

The School is well equipped with the necessary appliances for study and practical work. It contains large studios for life and elementary drawing, design rooms, lithographic studio, lithographic press room, photographic studio with electric light installation, dark rooms, colotype preparation and printing room (with three presses), etching rooms, lecture room, &c. Only those engaged in the trade are admitted. The inclusive fees are:—Session of from thirty to forty weeks, 10s.; those in receipt of less than 30s. weekly, 4s. 6d. a Session. Trade apprentices, learners, and improvers (under 21) admitted free. The Photo-Process Department is open for day instruction. Further particulars will be found in the prospectus of the School.

The Preparation of Sulphamide.—O. Ruff.—The author saturates 400 grms. of chloroform with ammonia gas, and into the strongly cooled liquid he lets fall, drop by drop, a mixture of 100 grms. of chloride of sulphuryl and 100 grms. of CHCl_3 , taking care to stir well between each drop. This operation is stopped when all the ammonia is consumed (the drops then no longer react violently). The liquid is again saturated with ammonia, and the operations are repeated until all the SO_2Cl_2 is used up. Saturate again with ammonia, for the last time, and let stand in a well-stoppered bottle. A pasty mass is left floating on the chloroform; this latter will serve for a further operation. The pasty mass is dried in the oven at 100° (all traces of moisture must be guarded against in these operations), and ground in a warm mortar with warm sand; the whole is then exhausted with acetic ether free from water for four or six hours. The sulphamide then crystallises easily from this solvent, giving a return of 8 or 9 grms. It is fusible at 92° .—*Berichte*, vol. xxxvi., p. 2900.

Ponderable or Gasometric Estimation of Phosphoric Acid and Magnesia, Based on the Molybdenum Method.—E. Riegler.—I. *Ponderable Estimation of Phosphoric Acid.*—When we pour chloride of barium into an ammoniacal solution of phosphomolybdate of ammonia, the phosphoric acid is precipitated entirely in the form of phosphomolybdate of barium, $\text{Ba}_{27}(\text{MoO}_4)_{24}\text{P}_2\text{O}_8 + 24\text{H}_2\text{O}$. The considerable molecular weight of this precipitate enables us to estimate traces of phosphorus with accuracy, say, from 10 to 50 m.grms. of P_2O_5 , to within 0.1 m.grm. II. *Gasometric Estimation.*—Phosphomolybdate of barium is precipitated by a titrated solution of chloride of barium. We measure the excess of the reagent by means of the volume of nitrogen given off on the addition of iodic acid, and then sulphate of hydrazine. III. *Ponderable Estimation of Magnesia.*—Transform the ammonio-magnesian phosphate into phosphomolybdate of ammonia, then into the barium salt. IV. *Gasometric Estimation.*—This is effected in the same manner as that of the phosphorus. These two latter methods can be applied to the estimation of the magnesia in waters.—*Zeit. Anal. Chem.*, vol. xli., p. 675.

Electrolytic Reduction of Carbonic Acid.—Alfred Cohn and Stefan Jahn.—The authors found that it is impossible to reduce carbonic acid in acid solution, or carbonates by electrolytic methods, while it has long been known that nascent hydrogen readily reduces carbonic acid and the bicarbonates of the metals of the alkalis and alkaline earths to salts of formic acid. From these negative results they conclude that it cannot be either the undissociated molecule (in the case of CO_2) on which the hydrogen acts, or the CO_3 ion which is present in solutions of carbonates. On the other hand, they found that on electrolysis solutions of sodium bicarbonate the formation of reduction products could be readily proved by titration with permanganate; further experiments showed that the only product was formic acid; formaldehyde, oxalic acid, &c., not being formed. The reduction of bicarbonate shows that it is the HCO_3 ion which undergoes reduction. The electrolytic reduction of carbonic acid results when electrodes are used from which hydrogen is discharged at a high potential. The only product at all potentials at which reduction occurs is formic acid.—*Berichte*, xxxvii., No. 12.

NOTES AND QUERIES.

* Our Notes and Queries column was opened for the purpose of giving, and obtaining information likely to be of use to our readers generally. We cannot undertake to let this column be the means of transmitting merely private information, or such trade notices as should legitimately come in the advertisement columns.

Rock Sections.—What are the best authorities to consult on the study of rock sections and the apparatus, &c., necessary to prepare them?—H. T. FRENCH.

Alchemy.—Could any correspondent furnish me with a list of the more important works on alchemy and the alchemists extant, in English or French, with publisher and price if possible?—ALEX.

BATTERSEA POLYTECHNIC, S.W.

Principal—SIDNEY H. WELLS, Wh. Sc. A.M.I.C.E., A.M.I.E.E.
Head of Department—JOHN WILSON, M.Sc.

SESSION begins on MONDAY, SEPT. 26th.

DAY and EVENING CLASSES in ORGANIC and INORGANIC CHEMISTRY (Theoretical and Practical) up to Hons. B.Sc. (London).
SPECIAL COURSES in TECHNOLOGICAL CHEMISTRY, e.g. Paper Making, Paper and Pulp Testing, Gas Analysis, Assaying, Oils, Fats, Soaps, and Candles.
Complete courses of instruction (including Engineering subjects, German, Physics, &c.) for intending Works Chemists and General Analysts.
The Laboratories are open for Research.
Prospectus gratis on application to the SECRETARY.
Detained Prospectus 14, post free 3d.

BIRKBECK COLLEGE,

Breams Buildings, Chancery Lane, E.C.

DAY and EVENING SCIENCE CLASSES—

CHEMISTRY	J. E. MACKENZIE, Ph.D., D.Sc.
PHYSICS	A. GRIFFITHS, D.Sc.
MATHEMATICS	E. H. SMART, M.A.
BOTANY	A. B. RENDLE, M.A., D.Sc.
ZOOLOGY	H. W. UNTHANK, B.A., B.Sc.
GEOLOGY & MINERALOGY	G. F. HARRIS, F.G.S.
METALLURGY, MINING, and ASSAYING	G. PATCHIN, A.R.S.M.

Classes in FRENCH, GERMAN, SPANISH, RUSSIAN, ITALIAN, DUTCH.

Courses for University of London, Conjoint Board, Dental, and Pharmaceutical Examinations.

PRACTICAL WORK in highly equipped Laboratories.

Perfect Order amongst your Scientific Papers, Research Records, &c.,

IS SECURED BY THE

“STOLZENBERG” SYSTEM of FILING.

Used by SIR WILLIAM CROOKES, LORD KELVIN, Royal Commission on Tuberculosis, Baden Aniline Works (50,000), and by thousands of private persons as well as Business Concerns.

Satisfaction guaranteed, otherwise goods taken back and money returned.

Sample Set, consisting of 12 best Files, 4to and fcap., with strong nickel-plated Perforator, and Patent Lifter, packed in leather-board box, 10/6 post free.

THE STOLZENBERG PATENT FILE CO.
50, Bishopsgate St. Without, London, E.C.

THE SIR JOHN CASS TECHNICAL INSTITUTE. JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.

EVENING CLASSES IN CHEMISTRY, METALLURGY, PHYSICS, and MATHEMATICS.

Designed to meet the requirements of those engaged in CHEMICAL, METALLURGICAL, and ELECTRICAL INDUSTRIES, and in trades associated therewith.

Also preparation for the B.Sc. Examination of London University. Every facility for Special and Advanced Practical Work in well-equipped Laboratories, both in the Afternoon and Evening.

CHEMISTRY [CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.]
PHYSICS R. S. WILLOWS, D.Sc., M.A.
METALLURGY C. O. BANNISTER, Assoc.R.S.M.
MATHEMATICS G. M. K. LEGGETT, B.A.

CLASSES IN METALLURGY.

GENERAL METALLURGY.

THE METALLURGY OF GOLD, SILVER, and LEAD.

FUEL and REFRACTORIAL MATERIALS.

METALLOGRAPHY, including PYROMETRIC WORK.

ASSAYING.

ANALYTICAL CHEMISTRY.

Including ELECTROLYTIC and GAS ANALYSIS.

Each Course of Lectures will be accompanied by suitable Laboratory Work.

GLASS BLOWING.

A series of Courses of Instruction will be given during the Session by Mr. A. C. COSBOR.

New SESSION begins MONDAY, SEPT. 26th.

The Institute is readily accessible, and near to Fenchurch Street, Liverpool Street, Broad Street, and Metropolitan Railway Stations. For details of the Classes apply at the Office of the Institute, or by letter to the PRINCIPAL.

W. H. DAVISON, M.A.,
Clerk to the Governing Body.

THE POLYTECHNIC,

309, REGENT STREET, W.

UNIVERSITY OF LONDON PREPARATION CLASSES.

Full Courses of Instruction for Matriculation,

Inter. Arts, Science, and Engineering, and Final Arts.
Special Courses for Final B.Sc. in Mathematics, Physics, and Chemistry.

Examinations are held at the above Institute.

NEXT TERM commences SEPTEMBER 16th, 1904.

Courses are so arranged that Students can do the work on Saturday and one evening per week.

Full particulars can be obtained on application to the DIRECTOR OF EDUCATION.

CITY OF LONDON COLLEGE, WHITE STREET and ROPEMAKER STREET, MOORFIELDS, E.C.

MICHAELMAS TERM commences OCTOBER 3rd.

CLASSES and LABORATORY WORK in CHEMISTRY, PHYSICS, BIOLOGY, BOTANY, GEOLOGY, and PHYSIOLOGY. Special preparation for the Examinations of the Pharmaceutical Society, The Conjoint Board. Complete Courses for University Matriculation and Inter. and Final B.Sc., meeting during the Evening and on Saturday.

Full particulars gratis on application to—

DAVID SAVAGE, Secretary.

SILICATES OF SODA and POTASH.

IN THE STATE OF SOLUBLE GLASS OR IN CONCENTRATED SOLUTION.

FULL STRENGTH GUARANTEED.

OLDEST and MOST RELIABLE MAKE.

Supplied on best terms by

WILLIAM GOSSAGE & SONS, Ltd., Soap Works, Widnes.

EAST LONDON TECHNICAL COLLEGE, MILE END ROAD, E.

Session 1904-1905, commencing September 19, 1904.

DAY and EVENING COURSES for the

B.Sc. (Honours and Pass) Degree of the University of London are conducted by the following Lecturers, who are recognised teachers of the University of London:—

Mathematics	{ J. L. S. HATTON, M.A., and
Physics	{ W. F. S. CHURCHILL, M.A.
Chemistry	{ R. A. LERFELDT, D.Sc., &c.
Botany	{ J. T. HEWITT, D.Sc., Ph.D., and
Engineering	{ C. SMITH, D.Sc.
Electrical Engineering	{ V. H. BLACKMAN, M.A.
	{ D. A. LOW, M.I.M.E.
	{ J. T. MORRIS.

The Day Courses in ENGINEERING and CHEMISTRY are also suitable for those entering manufacturing firms.

Calendar 24d. post free on application.

J. L. S. HATTON, Director of Studies.

THE CHEMICAL NEWS

Vol. XC., No. 2340.

THORIUM; CAROLINIUM, BERZELIUM.*

By CHARLES BASKERVILLE, Ph.D., F.C.S.

(Concluded from p. 153).

METZGER has published an interesting and novel method for separating thorium from cerium, lanthanum, and the didymium depending upon its precipitation from a neutral solution by a 40 per cent alcoholic solution of fumaric acid (*Journ. Am. Chem. Soc.*, xxiv., 901). The writer and Lemly† have verified these observations, as far as ordinary analytical methods are concerned. Applying it to the accepted chemically pure thorium, however, we obtained a filtrate less than one-half of 1 per cent, which, on evaporation and ignition, gave a greyish oxide possessing such marked radio-activity by the electrical method, that Dr. Pegram stated it acted as if "salted with radium."‡ This decayed very rapidly from 42 to 12.4 in eight days, to 3.3 in nine days more (uranium being taken as standard at unity). After thirty-two days more it gave 3, and was practically constant. The corresponding values obtained for the thorium precipitate, which constituted virtually the whole, were 0.63, 0.92, and 1. Truly but one interpretation of these results may logically be had, namely, the existence of a radio-active body with thorium, which is different from it. Crookes has sounded a timely warning against depending upon the photographic method for determining the radio-activity; so we have been guided mainly by the electrical method. Yet most interesting observations may be had by the photographic method, which has been used to secure very rough quantitative results, but by no means comparable to the other procedure. It aids one much in learning the β -activity, whereas the α -rays are the most important factor in the ionisation of gases upon which depends the electrical method. Persistent differences in radio-activity of the preparations had by different chemical methods have been noted, and the same method of preparation has given persistent differences in radio-activity measured by the same and different methods.

Rutherford (*loc. cit.*) and the Curies (*loc. cit.*) have shown that the α -radiations, or "emanations" according to the former, as adverted to, are readily driven away from radium halides and thorium oxides and condensed by liquid air. It does not come within the scope of this paper to discuss the nature of these emanations, which will be dealt with by the author and Lockhart§ in another communication. Suffice it to say that we have repeated this work successfully, and we have applied the same test to a large number of authenticated radio-active minerals, and in every case where those minerals have been known to contain helium we have succeeded in condensing the emanations from them. We have obtained the emanations from uranium and thorium bearing minerals, and we have failed to secure emanations condensed on a fluorescent zinc sulphide screen from minerals containing thorium.

The extremely interesting work by Rutherford, with his able associate, Soddy, and their students, on the regeneration of Thorium X, at first thought would apparently convince one that thorium is primarily radio-active, but this can be explained by the presence of minute amounts of a foreign highly active substance, which, so far, has failed

to be sufficiently concentrated for a thorough chemical examination, and yet exercises continually the novel property of inducing radio-activity. It is not hazardous to venture the opinion that it will prove to be actinium. In the light of the facts enumerated, however, it appears that thorium is not primarily a radio-active body any more than water containing a radium salt is primarily radio-active, because the radio-activity appears therein after it is distilled. It must be distinctly understood that no criticism is being passed upon the brilliant investigations progressing so successfully in the McGill laboratory on this extraordinary phenomenon of radio-activity, whatever be its source. It must be remembered that radio-activity is far more delicate than the spectroscopy; consequently a notable per cent of a body possessing that property may be present before any spectroscopic evidence may be had, as noted in Demarcay's work on radium. Further, the compounds of this element exhibit unusual radio-active strength before any change whatever is measurable in the atomic weight of the barium with which it is associated.

Although we have not as yet secured a thorium preparation free from any radio-activity, our observations confirm those of Rutherford and his co-labourers. The conclusion thus arrived at is that thorium as ordinarily extracted from mixed or complex minerals contains a primary radio-active body, perhaps similar to the truer thorium, but not necessarily so.

From what has been said, that which follows may be considered as if there were no such thing as radio-activity, as the amount of the body possessing that property is entirely negligible, from a spectroscopic standpoint, and far too small to produce the marked physical and chemical changes in pure thorium now to be briefly recounted.

Some years ago the writer and Davis began work on the atomic weight of thorium. A full account of the objections to the former methods will be given in due time. Working with materials from various sources such variable results were obtained that they could not be attributed to faulty methods. In the light of the research of Brauner and the observations made in this laboratory, the problem resolved itself into securing a pure substance, as free from its contaminating constituents as possible.

In the work of Jefferson and Smith on the separation of the rare earths by means of organic bases, it was stated that thorium gives a yellow precipitate with phenylhydrazine ("Aromatic Bases as Precipitants for Rare Earth Metals," *Journ. Am. Chem. Soc.*, 1902, xxiv., 540). Allen remarks that with pure thorium and pure phenylhydrazine the precipitate is white and quantitative (*Journ. Am. Chem. Soc.*, xxv., 421). Although Allen does not state that the source of this material was free from uranium, it may be that both of these observations are correct, as noted previously by the author and Lemly.* The precipitate produced by phenylhydrazine with very pure thorium is at first white and gelatinous, but soon acquires colour, doubtless due to decomposition of the precipitant. We have observed that fractionation of thorium can be brought about by means of phenylhydrazine. By addition of an insufficient amount of the reagent one obtains first a heavy flocculent precipitate, which soon acquires colour. On addition of more of the reagent there is obtained a gelatinous, white precipitate, which also acquires colour as the precipitant decomposes. These substances are different, as shown by variations in the radio-activity determined by both methods, and the solubility of the oxides in hydrochloric acid.

So far we have found it impracticable to fraction thorium compounds on a large laboratory scale with phenylhydrazine. The gelatinous precipitate clogs up the filtering media we have tried. Upward suction through unglazed porcelain, which has served so satisfactorily in much of the work on the rare earths in this laboratory, failed utterly.

* Presented before the New York Section of the American Chemical Society, April 8, 1904.

† Unpublished work.

‡ Personal correspondence. In time Dr. Pegram will no doubt publish a full discussion of all the results.

§ Soon to be published.

* Unpublished work. Reported in abstract at the Pittsburg meeting, 1902.

Attention must be directed to the fact that all the different constituents are precipitated by this reagent, but at different rates; hence the speed of the reactions was the point of attack. The difficulty was not one of simple filtration, which may be carried out readily enough after the precipitates have formed and settled, but of rapid separation, thus avoiding a second formidable hindrance, namely, decomposition of the phenylhydrazine with corresponding variations in the reactions. The use of a centrifuge offered promise. It was successful, and perhaps may be used on a commercial scale, although for reasons which follow it is not recommended. With the machine at our disposal we could work with but 20 c.c. at a time. The solution must be weak, and a small batch amounted to 10 litres. We regarded it essential that sufficient material be prepared for further purification and investigation, an ample supply being at hand through the generosity of the Welsbach Lighting Company. The writer did not feel that he had more time than the average allotment of life to a chemist, thirty years, so attempted a rough and ready settling and decantation with one lot of 10 litres, but with poor success. The old fractional precipitation of the rare earths by ammonia, complained of by Crookes, Hood, and others, is mere child's play in comparison with the time robbing and indefinite fractionation by this aromatic base. A separation of thorium into different constituents was brought about, as shown by atomic weight determinations of different portions. Fractions were had (as tetrad) giving 214, 228, 235, 242, 249, and 252; the original giving 232.5 and 232.6.

This procedure was temporarily abandoned to make use of the method earlier pursued in fractionation, and later in the efforts of Dr. Davis and myself to determine the atomic weight of thorium, namely, preparation of the pure crystalline tetrachloride by heating pure thorium dioxide mixed with pure sugar carbon in an atmosphere of chlorine. It is unnecessary in this paper to give the details of our procedure, which will be described later in full, further than to say we found it inadvisable to use hard combustion glass tubing, as variable amounts of contaminating chlorides were formed from the glass. We found we could not settle upon a definite correction for these impurities, as did Richards in his elegant work on uranium ("Atomic Weight of Uranium," Richards and Merigold, CHEMICAL NEWS, 1902, lxxxv., 177, 186, 201, 207, 222, 229, 249).

Quartz tubes, 2 c.m. in diameter made to order, were placed within large porcelain tubes, which rested in a powerful combustion furnace. A carbon boat containing the mixture of thorium oxide and carbon was inserted in the end of the quartz tube. Pure chlorine free from oxygen was carefully dried, as it issued from a cylinder, by elaborate desiccating apparatus, and led in by means of a smaller quartz tube, so that the stream of gas played directly into the boat. Arrangements were made by glass cocks to prevent a back flow of any volatile body that might be produced.

As previously noted by Berzelius and the author, when this method is followed out, there is obtained a volatile chloride, "weisser dampf," absorbable by alcohol, which, according to the former, is *not* thorium, yet comes from pure compounds of that element. This has been verified by applying the method to thorium obtained from a number of sources, including a small amount of very pure preparation used by Cleve in his atomic weight determinations, and presented to Dr. F. W. Clarke, of Washington, who kindly loaned the preparation to us. It therefore appears that the volatile chloride is to be had from thorium itself, or that material which separates with thorium in its extraction from various minerals.

Beautiful fern-like crystals of thorium tetrachloride formed on the inner walls of the quartz tubes. There remained in the carbon boat variable amounts of residue, largely converted into chloride, depending upon the temperature of the furnace and duration of the heating from two to ten hours. These accumulated residues were converted into the oxide and subjected to similar treatment

several times. With each repetition there were diminishing amounts of the volatile chloride and sublimed thorium tetrachloride formed. After the third re-distillation the oxide from the residue was digested in hydrofluoric acid and concentrated hydrochloric acid to remove accumulated impurities from the carbon and quartz tube. This oxide is *soluble in concentrated hydrochloric acid*, from which it may be crystallised by evaporation. This is not the novel thorium oxide, Th_2O_3 , described by Locke (*Zeit. Anorg. Chem.*, 1894, vii., 345), or that unique compound of thorium which has caused the spirited controversy between Stevens (*Ibid.*, 1901, xxvii., 41; 1902, xxxi., 368) and Wyruboff and Verneuil (*Ibid.*, 1901, xxviii., 90; 1902, xxxii., 376). The material thus obtained gave an atomic weight of 241.7 (tetrad).

This chloride was re-crystallised from concentrated hydrochloric acid three times, until the fine white needle-crystals appeared the same. The material was converted into the oxide by solution in water, in which it was readily soluble, giving a perfectly clear solution absolutely devoid of any opalescence (see Locke's chloride), precipitated by ammonia, and the washed white gelatinous hydroxide ignited in platinum. It was digested in turn with dilute hydrochloric, nitric, and hydrofluoric acids, washed with pure water, and brought to a constant weight.

In our first published work on thorium some store was laid by the specific gravities of the oxides of the several fractions as a means for watching the course of the disintegration. Some doubt was thrown upon this method of control through work of the writer and Mills,* as variations in the value of the same preparations were had depending upon the method employed. It was learned, however, that satisfactory comparable figures were obtained when the oxide was prepared in the same way each time.

The specific gravity of this oxide was determined:—

Amount taken. Grm.	Specific gravity.
0.7992	11.25
0.8973	11.27

The specific gravity of the original pure thorium oxide:—†

Amount taken. Grms.	Specific gravity.
2.0730	10.54
3.4573	10.51

The atomic weight was then determined:—‡

Oxide used.	Sulphate obtained.	Equivalent.	Atomic weight.
1.559290	2.434914	63.875	255.5
0.524254	0.819365	63.975	255.9
0.549331	0.854810	63.900	255.6

The familiar method used was essentially that of G. Krüss with certain variations, namely, a specially devised platinum lined asbestos jacketed bath was used, and the temperature judged by a thermometer in which mercury was under a pressure of 20 atmospheres, capable of registering 560° C. It was standardised by the Reichs-Anstalt.

It is scarcely the time or place to discuss the sulphate method, which will be dealt with fully later. It is well known that the method does not possess the most desirable degree of accuracy, but it answers entirely for such work as is here reported (see "Rare Earth Crusade," *Science*, N.S., May 15, 1903; CHEMICAL NEWS, lxxxviii., 18). The treatment with new amounts of sulphuric acid was continued until constant weights were had. It is, perhaps, just as well to state that the weights used were gold plated and corrected by the Bureau of Standards in Washington. The vibration method was used with a highly sensitive

* Unpublished.

† This work was done by the writer and S. Jordan, and will later be published in full.

‡ Unpublished—by the author and R. O. E. Davis.

Sartorius balance* resting upon a brick-cement pillar, and that the pans were so loaded each time with counterpoises and standardised platinum weights as to bring the apparatus to a determined point of the highest sensitiveness. Further, it may not be out of place to state at this point that after removal from the porcelain tube the material used did not come in contact with anything other than Jena glass and platinum; that the water, acids, and ammonia used were re-distilled in platinum, and gave no weighable residues after evaporation. The sulphuric acid was not re-distilled, but the very fine product especially secured gave no residue on evaporation of 50 c.c., and if it had it would have tended to lower the atomic mass value.

It is here quite interesting to note that Hofmann and Zerban (*Ber. Chem. Ges.*, 1903, xxxvi., 3093) state that the equivalent of "actinium" has been found to be 63.32, or 253.28 atomic weight, whereas that for pure thorium is 58.1, or 232.4 (O=16). Carolinium oxide shows a radio-activity of 0.56 and 0.6 (original thorium oxide = 1) by the electrical method. The two values were obtained from the same material after an interval of six weeks. Our preparation on heating almost to white heat gave off no "emanation" condensable by liquid air upon a zinc sulphide screen.

The volatile chloride was collected in part by its absorption in alcohol and condensation as acicular crystals in the cooler portions of the porcelain tubes. These were dissolved in water and the whole evaporated to dryness, the oxide digested by turn in hydrofluoric, concentrated hydrochloric, and nitric acids, and then dissolved in hot sulphuric acid (1:1), the gelatinous white hydroxide precipitated by ammonia, washed, and ignited to a constant weight in platinum.†

The specific gravity of this oxide was determined:—

Amount taken.	Specific gravity.
1.9207	8.442
1.8465	8.512

(On p. 766 in my former paper (*loc. cit.*) small amounts of oxides were obtained giving specific gravities 8.77, 8.47, and 11.26).

The atomic weight obtained, assuming its tetravalence:—

Oxide used.	Sulphate found.	Equivalent.	Atomic weight.
0.306778	0.505705	53.375	213.5
0.320618	0.530890	53.000	212.0
0.794692	1.309245	53.175	212.7

It is very interesting to note that the oxide obtained from this volatile chloride possesses very slight radio-activity, about one-third that of the original thorium when tested by the electrical method. An exposure to a sensitive photographic plate for seventy-two hours showed that it possesses radio-activity which affects the photographic plate to a very limited degree. It does not give off emanations condensed at the temperature of liquid air as judged by the effect on a phosphorescent zinc sulphide screen.

Although we know that this material is not yet pure, for reasons which will be given in the following, the novel properties mentioned above and its contrasting chemical conduct enumerated below, warrant the statement that we have a new element. Berzelius was the first to observe the formation of this "weisser dampf." On account of his beautiful pioneer researches in the difficult field, as the discoverer of thorium from which it comes, it is only proper that it should bear his name, so I have designated the element *Berzelium*, with the symbol Bz.

Just a few words concerning the new thorium, or thorium freed in a measure from carolinium and berzelium, are called for here, as that element will be treated of more fully in a later communication. In our former paper (*loc. cit.*,

p. 771) the values obtained for the atomic weight of thorium from the tetrachloride were 222–223.3. It was distinctly stated that the values were preliminary, and are not to be taken as final on account of the small amount of material used in each determination. More material has been secured, purified by treatment with acids, as mentioned above, and atomic weight determinations made according to the sulphate method. Following are the values found:—

Oxide used.	Sulphate found.	Equivalent.	Atomic weight.
0.425456	0.694934	55.15	220.6
0.740052	1.210405	55.025	220.1

Doubtless Chroustschoff's russium and Brauner's thorium a were quite pure preparations of thorium.

The source of heat for our furnace was gasoline gas, which does not have a constant pressure; consequently there can be no question but there is present in this middle portion variable but small amounts of carolinium and berzelium, and that some thorium is in the two extremes. We have just received a specially constructed electric oven from Heraeus and a Le Chatelier pyrometer, so that the process may be controlled with precision. This apparatus has been purchased through a grant from the Carnegie Institution received this year.

Although these constituents are not yet in the most desirable and highest state of purity, it became important to learn their comparative conduct under certain influences, physical and chemical.

It may be recalled that Kunz (*Science*, N. S., 1903, xviii., 769) and the author examined the action of ultra-violet light, Röntgen rays, cathode rays, and the complex radiations and emanations of radium rays upon a large number of gems and minerals in the Morgan-Tiffany and Morgan-Bement collections of the American Museum of Natural History in New York. At that time the writer also observed the action of many of the rare earth oxides of ultra-violet light produced by sparking high voltage currents between iron terminals (*CHEMICAL NEWS*, lxxviii., 262; *Am. Journ. Sci.*, 1903, xvi., 465). The dioxides of zirconium and thorium only became phosphorescent under such stimulation. One is radio-active, the other not. Uranium oxide, which is radio-active, did not respond. The new thorium oxide phosphoresced beautifully white on a five minute exposure, while berzelium and carolinium oxides gave negative results. Carolinium oxide containing variable amounts of thorium responded in proportion to the latter constituent present. We believe this is perhaps the first application of the method to the examination of material in the course of chemical investigations, as suggested by Kunz and Baskerville.

We have learned that ordinarily accepted pure crystalline thorium chloride, when thrown upon a filter-paper from concentrated hydrochloric acid, may be washed with water, a clear solution resulting. Berzelium and carolinium chlorides act similarly. When thorium is freed from these, the body will remain upon the filter-paper, and may be washed with concentrated hydrochloric acid, but as soon as pure water is added it hydrolyses and gives a turbid filtrate, acting in exactly the same way that titanium does. This was not suspected, although after the observation was made (by Jordan in this laboratory) it is no more than one might expect. As zirconium does not act like titanium, the natural inference is that it contains some hindering element, perhaps the earth reported by Hofmann and Frandl in zirconium from euxenite (*Ber.*, 1901, xxxiv., 1064).

The hydroxides of these three substances are white and gelatinous, insoluble in ammonium, sodium, or potassium hydroxide, readily soluble in the ordinary acids. Carolinium oxide is greyish with pink tinge, thorium white with merest tendency towards green, and berzelium has a more marked leaning towards green. These remarks are applicable to the substances in that state of purity so far had. The oxides of thorium and berzelium are not soluble in hot concentrated hydrochloric acid even when the digestion has lasted three weeks. Carolinium oxides dissolves slowly but completely within a few days, and the chloride forms

* Constructed for Dr. F. P. Venable; see his work on Zirconium, *Townsend Chem. Soc.*

† I have been assisted in this part of the work by P. Irwin.

fine crystals on concentration of the solution, quite different from ordinary thorium chloride. All three are readily precipitated by the ordinary thorium reagents, viz., ammonium oxalate, sodium thiosulphate, hydrogen dioxide, potassium periodate, &c. Their salts behave differently with various organic bases. Phenylhydrazine after a time in the cold gives a precipitate which becomes yellow, berzelium red, and thorium orange. Pyridine precipitates thorium at once, carolinium slowly, and berzelium with extreme slowness and incompletely. Xylidine precipitates both the former, but not berzelium. *o*-Toluidine gives a pinkish precipitate with thorium, a white flocculent one with carolinium, and none with berzelium. Thorium is completely precipitated by fumaric acid, carolinium only partially, a clear filtrate being had in both cases. Berzelium is precipitated nearly completely by fumaric acid; the filtrate is rendered opalescent by ammonia, however.

The solutions of none of these gave absorption bands. Dr. W. J. Humphreys, of the Rouss Physical Laboratory, University of Virginia, kindly examined the arc spectra with a Rowland grating, twenty-one feet in diameter, and 20,000 lines to the inch. His examination, covering the region between 3900 and 5500, showed some differences between berzelium and the other two, but his conclusion was that the differences in the spectra of those portions of the three materials which give arc spectra might be accounted for by impurities, or at any rate were not sufficient to warrant the statement from his spectral data that they are not the same.

Small portions of the impure materials have been sent to Sir William Crookes, by request, to be examined in the ultra-violet region with the apparatus used in his beautiful mapping of the spectrum of radium.

Summary.

1. The preponderance of evidence indicates that thorium is not a primary radio-active body.
2. There can be no question from the work of Chroustschoff, Brauner, Crookes, Rutherford, Auer, and the author, but thorium is complex and not a chemical element as we accept the term.
3. From the experimental data, physical and chemical, outlined in this communication, it appears that thorium has been resolved into at least three simpler substances, and that they are sufficiently identified to deserve distinct names.
4. The conservative position, in which the author coincides, concerning the acceptance of novel members of the family of elements, is the requirement of spark spectral confirmation. At the same time it must be kept in mind that even spectral work requires unification.*
5. As stated above, one of the objects of this paper is to present work to guide others, and seek confirmation in other hands. While we shall be busied with the investigation, instead of asking a reservation, we would invite others to assist in solving the problem.

University of North Carolina
April, 1904.

Addendum.

Since the paper was written and presented, a letter from Sir William Crookes has been received, excerpts from which are given herewith. "I had not quite sufficient to enable me to photograph the whole ultra-violet spectrum, but I have taken that portion, between wavelengths 3444.020 and 4071.903, which contain some very characteristic thorium lines. I compared the spectra with my standard thorium spectrum taken from the spark between poles of metallic thorium. Making allowance for the fact that my spectrum is from the metal, while that from your material is from the chloride solutions, the five spectra are practically identical, all the prominent lines being seen in each spectrum, while there are no lines in one

which are not seen in the others. . . . You must not attach too much importance to these spectrum results. All I can say is that they give no positive proof of the existence of anything new. But they by no means prove that such bodies do not exist. They may be there with their spectra masked by the thorium which is present."

As only a limited portion of the spectrum was examined, the question is still an open one. My sincere thanks are due to Sir William Crookes.

ISOMERISM OF α - AND β -CROTONIC ACIDS.*

By R. S. MORRELL AND E. K. HANSON.

THE isomerism of α - and β -crotonic acids has been investigated by a number of chemists, amongst whom the names of Geuther, Michael, and the late J. Wislicenus are most prominent. Michael (*Journ. f. Prakt. Chem.* [2], xlv., 236) has described the method he used to obtain the β -crotonic; and Wislicenus, by a modification of the same method, obtained the β -acid in the crystalline condition.

In an earlier communication (Morrell and Bellars, *Journ. Chem. Soc.*, lxxxv., 345) use was made of the quinine salt for the separation of the β -acid from its isomer contained in the ordinary "isocrotonic acid." It is quite easy to separate the quinine β -crotonate from the α -crotonate by fractional crystallisation, as the former is much less soluble in water. From the quinine salt, barium β -crotonate was next prepared, and, by acidifying with dilute sulphuric acid and extraction with ether, crotonic acid melting at 15° C. was obtained in the form of feathery needles, which possessed all the properties ascribed to it by Michael and Wislicenus.

The present investigation divides itself into two parts:—
1. Observation of the depression of the freezing-point of the isomeride by addition of the other.

2. Determination of the equilibrium mixtures in the liquid condition at varying temperatures.

The freezing-point curve is a continuous one, and there is a eutectic point at a temperature not far from -3° C.

It will be noticed that no mixture gave a freezing-point approaching -20°, whereas the so-called "isocrotonic acid" does not solidify at -20° C.

This point is one of great interest, and it seems to us possible that the explanation may lie in the formation of a compound between the α - and β -acids at temperatures above the melting-point of the α -acid. This compound could easily form a eutectic mixture with the β -, or even with the α -acid. This might not solidify at -20°. Light, it is hoped, will be thrown upon this by the second part of the work, which is as yet incomplete.

THE CONSTITUTION OF PHTHALEIN SALTS.†

By Prof. RICHARD MEYER.

THE author presented a report on his experimental work on the constitution of phthalein salts at the last *Versammlung Deutscher Naturforscher und Aerzte*, at Cassel (*Ber.*, 1903, xxxvi., 2949).

Phenolphthalein itself is colourless, and is generally regarded as a lactone, whilst the quinonoid formula is assigned to its red alkali salts by the majority of chemists. Fluorescein, being coloured both in the free state and in the form of salts, is regarded as being quinonoid either when free or combined.

Quinolphthalein (I.), the constitution of which has been confirmed by work done in the author's laboratory, does

* Abstract of a Paper read before the British Association (Section B), Cambridge Meeting, 1904.

† Read before the British Association (Section B), Cambridge Meeting, 1904.

* See my Address before Section C, American Association for the Advancement of Science, St. Louis Meeting, December, 1903.

not come into quite the same category, and its red alkali salts must be supposed to possess a meta-quinonoid constitution (II. or III.),—

Metaquinones being at present unknown, further work on the above substances was desirable, and the author and his assistant, Mr. O. Sprengler, have therefore studied the ethers and oximes of phenol- and quinol-phthalein, preparing these substances in alkaline solution; the results of this work point to the lactonic formula of the alkali salts as being correct, both in the case of quinolphthalein and of phenolphthalein. They drew attention recently to the fact that the anilides of the phthaleins dissolve in alkali without giving rise to colouration; if these anilides have the same constitution as the phthaleins themselves, this distinction might arise from a difference in basicity. They therefore endeavoured to ascertain the equivalents of these substances. A measured volume of standard caustic soda solution was treated for two hours at the ordinary temperature with an excess of phenolphthalein; in a second and a third experiment quinolphthalein and phenolphthalein anilide was subjected to similar treatment. The undissolved residue was filtered off and washed, the filtrate being then precipitated with dilute sulphuric acid; the precipitates were filtered, washed, dried, and weighed. The results agreed with the formulæ $C_{20}H_{12}O_4Na_2$, $C_{20}H_{10}O_5Na_2$, and $C_{20}H_{12}O_3(NC_6H_5)Na_2$. Thus all three compounds behave alike as dibasic acids, and from this point of view no difference is traceable between the anilide and the free phthaleins; the anilide is, however, more feebly acidic than the phthaleins, being precipitated by the latter from its alkaline solution.

These experiments have some bearing on those published recently by A. G. Green and A. G. Perkin, but the results of these investigators differ from the present because they worked under different conditions.

The authors have made many attempts under varied conditions to obtain a quinonoid ether of phenol- or quinolphthalein, employing methyl-iodide and methyl sulphate, both in aqueous and alcoholic solutions, and using an excess of alkali and also of sodium methoxide. In each case the same di-ethers as before were obtained; they are colourless, and doubtless possess a lactonic constitution. Only when the neutral sodium salts of the two phthaleins are treated, two new compounds are formed in addition to the well known di-ethers. These substances proved to be the mono-ethers, $C_{20}H_{12}O_3.OCH_3$ and $C_{20}H_{11}O_4.OCH_3$, and are not carboxylic but hydroxylic ethers; they could not be saponified, and on further treatment with alkyl salts yielded the lactonic ethers. They do not decompose sodium carbonate, and hence do not contain a free carboxyl group; moreover, they are colourless, and are doubtless of lactonic constitution, just as are the di-ethers. They form, however, red salts, the constitution of which is open to discussion.

The quinonoid formulæ of the phthaleins indicate the presence of one carboxyl and one phenolic hydroxyl group in the molecule, whilst, according to the lactonic formula, two phenolic hydroxyl groups are present. The etherification conditions of carboxylic acids and phenols were therefore studied, as it appeared of prime importance to ascertain whether the carboxyl group can be esterified under the conditions prevailing in the present experiments, namely, in neutral or alkaline solution. The following facts were established as the result of numerous experiments carried out under a great variety of conditions:—Phenol is always converted into its ethers by means of alkyl halogen salts and by methyl sulphate, whether the solution be alkaline or neutral, or even acid; the only point of difference is in the yield obtained. Benzoic acid, however, can only be esterified in acid or neutral solutions, but not in alkaline ones, whether alkyl halogen salts or methyl sulphate is used.

It would seem difficult to reconcile the above results with the quinonoid formula of the phthalein salts; the difficulty involved in the assumption of the quinonoid theory is also felt by A. G. Green and A. G. Perkin, and they attempt to overcome it by assuming the intermediate formation of the carbinol salt. This view would indicate that the red solution contains, in addition to the quinonoid salt, a certain proportion of carbinol salt, from which latter the lactonic ethers are produced; and that during the course of the reaction the quinonoid salt is progressively converted into carbinol salt, in accordance with the law of mass action, until the change has become complete. The carbinol salt could only be formed by opening the ring, and this could only take place whilst working in presence of excess of alkali; since, however, the author has obtained the same lactonic di-ethers in neutral solution, the opening of the lactonic ring in this case would appear to be impossible.

The advocates of the quinonoid theory point to analogies between phenolphthalein and fluorescein, but the author is of opinion that it would be very difficult to find, in one group of chemically related compounds, two substances more dissimilar than are phenolphthalein and fluorescein. Thus, for instance, R. Nietzki and P. Schroeter obtained one lactonic and three quinonoid ethers by the alkylation of fluorescein, whilst the salts of phenol- and quinolphthalein never yielded quinonoid derivatives under the most varied conditions of working. The quinonoid ethers of tetrabromophenolphthalein, discovered by R. Nietzki and E. Burckhardt, have no bearing on this question, because they have not been prepared from the phthalein salts. It would be preferable to try to express the different behaviour of fluorescein and phenolphthalein by the aid of chemical formulæ rather than to insist on a similarity which is not warranted by the facts.

One serious difficulty arises in connection with the colour of the alkali salts. Ostwald assumes that the red colour is due to the phthalein ions, whilst the undissociated molecules are colourless. If, however, the ions are coloured, they should contain a chromophoric group, such as is present in undissociated coloured molecules; the lactonic formula does not indicate the presence in the molecule of such a chromophoric group. At the same time, it must be agreed that, however valuable the theory of chromophors has proved as a means of characterisation and classification of colouring matters, it is not sufficiently comprehensive to include all coloured organic compounds. It does not include the quinolphthaleins (and orcinphthalein), dibenzalacetone, and other colourless substances which form feebly coloured addition compounds with mineral acids. Adolf Baeyer introduced the term "halochromy" as descriptive of this phenomenon, and it does not seem impossible that the colour of phthalein salts is due to a kind of halochromy.

The author is continuing his work in another direction, and hopes to obtain further evidence bearing on this question.

NOTE ON

THE INFLUENCE OF RADIUM RADIATIONS
ON ATMOSPHERIC OXIDATION
IN PRESENCE OF IRON.*

By HENRY J. HORSTMAN FENTON, F.R.S.

It has been pointed out by the author in previous communications (*B. A. Report*, 1895 and 1898) that the oxidation of certain hydroxy-compounds, such as tartaric acid or glycol, in presence of iron, may be brought about by atmospheric oxygen in presence of sunlight, and that the products are the same as those obtained when hydrogen dioxide is employed as oxidising agent. It is now found that the influence of radiations from radium bromide may, in certain cases, produce effects similar in this respect to those obtained by exposure to sunlight. A solution of tartaric acid, for example, containing a small quantity of ferrous tartrate, was divided into two parts and kept in the dark in presence of air, one of the tubes being placed directly over a specimen of radium bromide. On testing the solutions after a day or two with phenylhydrazine acetate a very striking difference was observed in the results, the exposed solution giving the larger yield of Nastvogel's osazone.

THE

STUDY OF HYDRO-AROMATIC SUBSTANCES.†

RECENT WORK ON HYDRO-AROMATIC SUBSTANCES.

By Dr. A. W. CROSSLEY.

THE following is a summary of the work published on hydro-aromatic compounds since the preparation of the last report (*Reports*, 1903, p. 179).

Petroleum.—Roumanian petroleum (Poni, *Journ. Chem. Soc.*, 1903, Abstract, [1], 593) resembles Russian and American petroleum, inasmuch as the densities of fractions taken every 2° between 50° and 70° diminish to a minimum at 60° to 62°, and then continuously increase, whilst in the case of Galician oil there is a steady increase of density throughout. A further difference from this latter oil is to be found in the composition of the fractions between 60° to 100°, which do not contain secondary hexanes, as on nitration they yield aromatic derivatives only. Methyl- and ethyl-hexahydrobenzene are among the hydrocarbons contained in the Roumanian oil.

Hydrocarbons.—Sabatier and Senderens (*Comptes Rendus*, 1901, cccxii., 1254) have shown that, when benzene or its homologues, containing methyl groups as side-chains, are passed together with hydrogen over reduced nickel, hydrogenation takes place without complication; whereas if the hydrocarbons contain longer side-chains (ethyl, propyl, &c.) part of the latter is split off. For example, ethylbenzene gives principally ethylhexahydrobenzene, but also small amounts of methylhexahydrobenzene. Sabatier and Mailhe (*Comptes Rendus*, 1903, cccxvii., 240) have further investigated the product obtained by passing benzene and hydrogen over reduced nickel, and find that if the temperature be maintained at 250° pure hexahydrobenzene is formed, identical in all respects with that occurring in Caucasian petroleum. If hexahydrobenzene be passed over reduced nickel at 270° to 280°, it is decomposed into benzene and hydrogen, which latter reacts with the benzene, forming methane. An energetic substitution reaction takes place when chlorine acts on hexahydrobenzene at a temperature of 0°, resulting in the formation of a mixture of mono-, di-, tri-, tetra-, and hexachloro-derivatives (*Bull. Soc.*, 1903, xxix., 974).

According to Markownikoff (*Cent. Blatt.*, 1904, [1], 1345), methylhexahydrobenzene has not been obtained pure by the methods so far described; for example, when isolated from Caucasian petroleum, it is contaminated with normal heptane. It can, however, be prepared in the pure condition by the action of zinc dust on an aqueous alcoholic solution of 3-bromo-1-methylhexahydrobenzene. The hydrocarbon obtained by eliminating the elements of hydrogen bromide from this latter substance is a mixture of the two methyltetrahydrobenzenes with the double bonds in the 2:3 and 3:4 positions (*Cent. Blatt.*, 1904 [1], 1346). The pure substances have been obtained by other methods (*Cent. Blatt.*, 1903, [2], 289; 1904, [1], 1213; Wallach, *Annalen*, 1903, cccxxix., 368). In such hydrocarbons the influence of the side-chain is such that in the splitting off of hydrogen together with a halogen, or in the combination with a molecule containing mobile hydrogen, the latter splits off from, or combines preferably with, the carbon atom furthest removed from the side-chain, whilst the electro-negative element combines with the carbon nearest the side-chain, i.e. 1:3-trimethyl- Δ^4 -tetrahydrobenzene (Harries and Weil, *Ber.*, 1904, xxxvii., 848).

Hydroxy-derivatives.—The reaction introduced by Sabatier and Senderens has been extended to the preparation of aromatic alcohols. When phenol is passed together with excess of hydrogen over reduced nickel at a temperature of 140–160°, pure hydroxyhexahydrobenzene is obtained (Holleman, *Cent. Blatt.*, 1904, [1], 727; Brunel, *Comptes Rendus*, 1903, cccxxvii., 1268; Sabatier and Senderens, *Ibid.*, 1903, cccxxvii., 1025); but if the temperature be raised to 215–230°, the hydroxyhexahydrobenzene first formed is decomposed into ketohexahydrobenzene and hydrogen. From the mixture so produced Sabatier and Senderens have obtained the pure alcohol or ketone by, in the first case, passing the product with excess of hydrogen over reduced nickel at a temperature of 140–150°, and in the second by passing the product without hydrogen over reduced copper at a temperature of 330°. Under similar conditions thymol and carvacrol are converted into the corresponding hexahydro-derivatives (Brunel).

Iodo-hydroxyhexahydrobenzene gives, when treated with potash or silver oxide (Brunel, *Comptes Rendus*, 1903, cccxxvii., 62), the internal oxide of 1:2-dihydroxyhexahydrobenzene,—

into which substance the former is easily converted by the action of water. When the internal oxide is treated with alcoholic ammonia (Brunel, *Comptes Rendus*, 1903, cccxxvii., 198), there result 1-amino-2-hydroxyhexahydrobenzene and two forms of dihydrocyclohexylamine, $\text{NH}(\text{C}_6\text{H}_{10}\cdot\text{OH})_2$.

Power and Tutin have isolated a laevorotatory modification of quercitol from the leaves of *Gymnema sylvestre* (*Journ. Chem. Soc.*, 1904, lxxxv., 624). It is demonstrated that this substance has the same constitution as d-quercitol (pentahydroxyhexahydrobenzene) which has been established by Kiliani and Schaefer (*Ber.*, 1896, xxix., 1762), and can only differ from the latter stereochemically; but, since d-quercitol has $[\alpha]_D + 24.16^\circ$, whilst the new quercitol has $[\alpha]_D - 73.9^\circ$, the one cannot be the optical antipode of the other. Eight optically active modifications of pentahydroxyhexahydrobenzene are possible, and until a further number of these isomerides are known it is impossible to assign a definite configuration either to d-quercitol or to the new l quercitol.

Aldehydes and Ketones.—The general method for the preparation of aldehydes by the action of organomagnesium haloids on the esters of orthoformic acid dissolved in dry ether (Tschtischabin, *Ber.*, 1904, xxxvii., 186) appears to be applicable to the synthesis of hydro-aromatic aldehydes (*Ber.*, 1904, xxxvii., 850), and in this way hexahydro-m-

* Read before the British Association (Section B), Cambridge Meeting, 1904.

† Report of the Committee, consisting of Dr. E. Divers, F.R.S. (Chairman), Dr. A. W. Crossley (Secretary), Professor W. H. Perkin, F.R.S., Dr. M. O. Forster, and Dr. H. R. Le Sueur. Read before the British Association (Section B), Cambridge Meeting, 1904.

toluic aldehyde has been prepared from 3 bromo-1-methyl-hexahydrobenzene.

The preparation of hexahydrobenzyl alcohol has been described by Bouveault (*Comptes Rendus*, 1903, cxxxvii., 60). Methylhexylcarbinol, $C_6H_{11}.CH(CH_3)OH$, is obtained when acetic aldehyde is allowed to act on the magnesium compound of chlorohexahydrobenzene (*Bull. Soc.*, 1903, xxxix., 1049). When these alcohols are oxidised with chromic acid the former yields hexahydrobenzaldehyde and the latter hexahydroacetophenone.

Chloro-derivatives of Ketomethylidihydrobenzene
(Zincke, *Annalen*, 1903, cccxxviii., 261).

Acids.—When pentane- $\gamma\gamma\gamma$ -tricarboxylic acid is digested with acetic anhydride, and then distilled (Perkin, *Journ. Chem. Soc.*, 1904, lxxxv., 416), a remarkable decomposition takes place, with elimination of carbon dioxide and water and formation of δ -ketohexahydrobenzoic acid,—

On reduction the corresponding hydroxy acid is obtained, which yields trans- δ -bromohexahydrobenzoic acid when treated with hydrogen bromide, and this bromo-acid, under the influence of sodium carbonate, gives rise to Δ^1 -tetrahydrobenzoic acid. δ -Ketohexahydrobenzoic acid combines with hydrogen cyanide to form the mixed nitriles of the *cis*- and *trans*-modifications of α -hydroxyhexahydroterephthalic acid. Both the corresponding acids decompose on distillation with formation of Δ^1 -tetrahydroterephthalic acid, identical with the acid synthesised by Baeyer (*Annalen*, 1888, ccxlv., 160).

FIG. 1.

δ -Ketohexahydrobenzoic acid has been used by Perkin (*Journ. Chem. Soc.*, 1904, lxxxv., 654), as the starting point for the synthetical preparation of terpin, inactive terpineol, and dipentene; but as this report does not include a consideration of the terpenes and camphors, an account of this work is not given.

Transformations.—1-Methyl-3-ketohexahydrobenzene has been converted into 1-methyl-2-ketohexahydrobenzene (Wallach, *Annalen*, 1903, cccxxix., 368) by the series of reactions already described (*Reports*, 1903, p. 181).

When 1:5-dimethyl-3-keto- Δ^1 -tetrahydrobenzene (Knoevenagel and Erler, *Ber.*, 1903, xxxvii., 2129) is heated with an equal weight of ammonium carbonate, a small quantity of a base is formed identical with collidine (2:4:6-trimethylpyridine). The mechanism of this process is the exact reverse of Hantzsch's reaction whereby dihydropyridine, under the influence of hydrochloric acid, yields ketotetrahydrobenzene (*Annalen*, 1882, ccxv., 297).

It has been shown by Demjanow and Luschnikov (*Cent. Blatt.*, 1903, [1], 828) that it is possible to convert a substance containing a tetramethylene ring into one containing a pentamethylene ring (cyclopentanol from tetramethylenemethylamine); and, in continuance of this work, Demjanow has now provided an example of the conversion of a ring containing six carbon atoms into one containing seven (*Cent. Blatt.*, 1904, [1], 1214). On distilling hexahydrobenzamide with phosphorus pentoxide it yields cyanohexahydrobenzene (1), which on reduction gives the corresponding amine (2). When the hydro-

chloride of this amine is acted on with silver nitrite it is converted into an alcohol identical in every respect with suberyl alcohol (3), already described by Markownikoff (*Ber.*, 1893, xxvi., R, 813).

A study of the action of bromine on 3:5-dichloro-1:1-dimethyl- Δ^2 :4-dihydrobenzene (Crossley, *Journ. Chem. Soc.*, 1904, lxxxv., 264) has shown that the resulting hydro-aromatic bodies very readily lose hydrogen bromide to form aromatic substances, of which the two principal ones are 3:5-dichloro-4-bromo-*o*-xylene and 3:5-dichloro-6-bromo-*o*-xylene. Since the dichlorodimethylidihydrobenzene, which forms the starting-point of the research, contains the *gem*-dimethyl group, the migration of one of these methyl groups becomes an essential step in the production of an aromatic compound. The reaction has therefore been worked out so as to gain an insight into the course of such changes, more especially as, on account of the symmetry of the molecule, it forms one of the simplest cases in which the wandering of an alkyl group can take place. The reaction is largely influenced by the condition of experiment, but no substance has been encountered in which an alkyl group has wandered into any but an ortho-position.

The Nature of Double Linkings.—Recent experimental work has enriched our knowledge of the behaviour of

FIG. 2.

substances containing double linkings, more especially as regards the property of addition. In the case of a substance containing several double bonds in the molecule, these bonds often do not behave independently of one another. Thiele's theory (*Annalen*, 1899, cccvi., 87) of partial valencies provides a possible explanation of many such cases. Knoevenagel (*Ber.*, 1903, xxxvii., 2803) considers it essential to study the movement of the atoms themselves in the molecule, and assumes that doubly linked carbon atoms are in a continuous state of oscillatory motion. In the case of a substance, such as butadiene, the formation of the dibromide $BrCH_2-CH=CH-CH_2Br$ is explained by supposing the swinging motion of the carbon atoms to be taking place first in one direction and then in the opposite, as indicated in the accompanying diagram (Fig. 1).

Continuous motion in one direction only is prevented by the hydrogen atoms attached to the terminal carbon atoms, which come into the plane of rotation. It is quite another matter in the case of benzene, where alternate carbon atoms are supposed to rotate continuously in opposite directions, because none of the valencies which pass into the plane of rotation have hydrogen atoms attached to them; the result is that the double linkings change their position and travel round the ring (Fig. 2).

Such a theory indicates the possibility of new types of isomerism, more subtle even than optical isomerism, and it is pointed out that cases of supposed polymorphism, e.g., the quinols and benzophenone, may be in reality mani-

festations of structural differences of the above type. Knoevenagel supports Lehmann's view ("Molekularphysik," ii., 413), that substances exhibiting difference in crystalline form afford evidence of difference in chemical or, perhaps better, physical constitution.

It is also suggested that bodies of the type of ethyl $\Delta^2:5$ -dihydroterephthalate should be particularly liable to lose a molecule of hydrogen, since the two hydrogen atoms

marked (+) would be in a continuous state of bombardment, due to the swinging motion of the carbon atoms connected by a double bond. On increasing the temperature this state of things would become sufficiently intense to cause the partial dissociation of the molecule with evolution of hydrogen. This actually happens in the case of the above ethereal salt on heating (*Ber.*, 1903, xxxvi., 2857) in an atmosphere of carbon dioxide, especially in presence of platinum black. The evolved hydrogen is much smaller in amount than required by theory, only 18 c.c. being obtained by heating 1 grm. of the salt instead of 113 c.c. This is readily explained, for the evolved hydrogen combines with some unaltered ester, and the result of the reaction is the production of methyl terephthalate and methyl hexahydroterephthalate.

$\Delta^1:3$ -DIHYDROBENZENE. By Dr. A. W. CROSSLEY.

In the last report of this committee (Southport, 1903, p. 182) brief allusion was made to the preparation of $\Delta^1:3$ -dihydrobenzene; work in this direction has now been completed, with results which entirely confirm the preliminary experiments. The hydrocarbon obtained from dimethyldihydroresorcin by Crossley and Le Sueur (*Journ. Chem. Soc.*, 1902, lxxxi., 822) was proved to be 1:1-dimethyl- $\Delta^2:4$ dihydrobenzene, and by submitting

dihydroresorcin to an identical series of reactions a hydrocarbon was obtained (Crossley and Haas, *Journ. Chem. Soc.*, 1903, lxxxi., 494), which differed from any previously prepared dihydrobenzene in only combining with one molecule of bromine to give a dibromodihydrobenzene melting at 104.5°. It was therefore suggested that the double bonds would be in the position 1:3, and the hydrocarbon prepared by Baeyer (*Annalen*, 1894, cclxxviii., 88) and Markownikoff (*Annalen*, 1898, ccxii., 29) would be $\Delta^1:4$ -dihydrobenzene, which is characterised by directly adding on four atoms of bromine to form a solid tetrabromide melting at 184°. Harries and Antoni (*Annalen*, 1903, cccxxviii., 102) consider that their work proves this suggestion to be incorrect.

Unfortunately it was not found possible to prepare pure $\Delta^1:3$ -dihydrobenzene from dihydroresorcin, but this end has now been attained by the removal of the elements of hydrogen bromide from dibromotetrahydrobenzene (*Proc. Chem. Soc.*, 1904, xx., 160):—

The reaction can only take place in one way, and therefore leaves no doubt as to the constitution of the resulting hydrocarbon, which like that obtained from dihydroresorcin only adds on two atoms of bromine to give a solid melting at 104.5°. That this latter substance is in reality a dibromodihydrobenzene is conclusively proved by the fact

that on treatment with quinoline it loses two molecules of hydrogen bromide, yielding benzene.

It seems indisputable that, as already suggested, the hydrocarbon obtained from dihydroresorcin or from dibromotetrahydrobenzene is $\Delta^1:3$ -dihydrobenzene, and the hydrocarbon giving the tetrabromide melting at 184° must therefore be $\Delta^1:4$ -dihydrobenzene.

ON ACTIVE CHLORINE.*

(PRELIMINARY NOTE).

By D. L. CHAPMAN and C. H. BURGESS.

We much regret that the necessity to be brief prevents us from referring to the work of others as we should like, and also from entering into any experimental details connected with our own work, or even from explaining fully the views which we hold, on this subject and on subjects closely allied to it. We hope, however, to be able to show that some of the theories which have been proposed to account for the phenomenon known as the induction period cannot be reconciled with the newly discovered facts, and that the theories in question will have to be modified, perhaps to the extent of admitting new conceptions into the science. It will be best now to describe, leaving any criticism until later, those theories which account both for the induction period and for the catalytic action of water.

The theories in question postulate the gradual formation of an intermediate compound as the result of the interaction of one or both of the reacting substances with the catalyser. Since the intermediate compound may be conceived as differing in its mode of action it will be convenient to adopt a rough classification.

In the first place, it may be assumed that the compound is formed and subsequently destroyed; for example, it may be supposed that the changes which take place are represented by the equations:—

- I. $\begin{cases} a. \text{H}_2\text{O} + \text{Cl}_2 = \text{H}_2\text{O} \cdot \text{Cl}_2. \\ b. \text{H}_2\text{O} \cdot \text{Cl}_2 + \text{H}_2 = \text{H}_2\text{O} + 2\text{HCl}. \end{cases}$
- II. $\begin{cases} a. \text{H}_2\text{O} + \text{Cl}_2 = \text{HCl} + \text{HClO}. \\ b. \text{HCl} + \text{HClO} + \text{H}_2 = 2\text{HCl} + \text{H}_2\text{O}. \end{cases}$
- III. $\begin{cases} a. \text{Cl}_2 + \text{H}_2\text{O} = \text{Cl}_2\text{O} + \text{H}_2. \\ b. \text{Cl}_2\text{O} + 2\text{H}_2 = 4\text{HCl} + \text{H}_2\text{O}. \end{cases}$
- IV. $\begin{cases} a. \text{Cl}_2 + \text{H}_2\text{O} = 2\text{HCl} + \text{O (nascent)}. \\ b. \text{O (nascent)} + \text{H}_2 + 2\text{HCl} = 2\text{HCl} + \text{H}_2\text{O}. \end{cases}$

Of these theories I. and III. are excluded by direct experiment, since it has been shown that an induction period still occurs even after the introduction of chlorine monoxide or hypochlorous acid into the system.

In the second place, it may be supposed that the intermediate compound is not destroyed, but that it simply acts as a catalyser in the presence of which the combination of the hydrogen and chlorine can more readily take place. The actions represented by the equations below is an example of this:—

$$\text{V. } \begin{cases} a. \frac{n}{m} \text{H}_2\text{O} + m \text{Cl}_2 = (\text{H}_2\text{O})_n \text{Cl}_{2m}. \\ (\text{H}_2\text{O})_n \text{Cl}_{2m} + \text{Cl}_2 = \text{Cl}_2 \{ (\text{H}_2\text{O})_n \text{Cl}_{2m} \}. \\ \text{Cl}_2 \{ (\text{H}_2\text{O})_n \text{Cl}_{2m} \} + \text{H}_2 = 2\text{HCl} + \{ (\text{H}_2\text{O})_n \text{Cl}_{2m} \}. \end{cases}$$

Leaving for the present the consideration of these two classes of hypothesis, I will describe some experiments which have been selected as illustrations.

Experiments on the Influence Exerted by the Liquid contained in the Actinometer.

The actinometer was a modification of the one used by Bunsen and Roscoe, and is shown in Fig. 1. Measured quantities of liquid or gas can be introduced at any time. The capacity of the bulb was 70 c.c., and the length of the index about 1 metre. For comparative experiments almost

* Read before the British Association (Section B), Cambridge Meeting, 1904.

precisely similar actinometers made from the same glass were used.

If such an apparatus containing electrolytic gas and a little water is exposed to light, there is for some time after it is first exposed no appreciable movement of the index. Then a slight movement is observed, which increases rapidly until a maximum and constant rate is attained. The time from the first exposure to light to the attainment of the constant rate has been named by Bunsen and Roscoe the induction period. It was accidentally discovered that if after this stage is reached the actinometer be removed from the bath, thoroughly shaken in the dark, and re-exposed to light, a new induction period is observed, which is, however, not so long as the first period. The same operation may be repeated with the same result, namely, there is each time a fresh induction period which is always shorter than the one immediately preceding. The numbers below are the lengths of the successive induction periods in an experiment of this kind.

Periods	I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.	X.
Minutes	28	18	13	12	12	8	6	5	3	1

The same phenomenon was observed when the actinometer contained acid or saline solutions in the place of water.

The explanation of the foregoing results is obvious. By the action of light on the moist mixture of hydrogen and chlorine they acquire the power of combining more readily with one another, or, concisely, they become active. The power of combining more easily, or the *activity*, is removed when the gases are shaken with the water contained in the actinometer, but in time this water becomes saturated with activity, and when this is the case it is no longer able to render the mixed gases inactive.* The best method, therefore, of inducing the gases is to expose them frequently to light, and then to shake them with the liquid contained in the vessel. If the gases are thoroughly induced in this way a sudden exposure to even a weak light is accompanied by a sudden expansion. This expansion with a weak light can be used as a test of the thoroughness of the insulation of the mixture.

There are several peculiarities connected with the absorption of the activity by various liquids, and also with the rate of decay of the activity, which must be left until a fuller account of the work can be given.

* As I shall frequently have to refer to a liquid in this condition, it will simply be described as an active liquid.

There is another relation which, although it is not connected with the main argument, is of importance in connection with the right interpretation of many experiments, namely, the influence of small quantities of air on the length of the induction period. Bunsen and Roscoe have shown that the addition of small quantities of air decrease in a remarkable degree the sensitiveness of electrolytic gas. Does it increase the length of exposure to a given light required to make the gas active? To test this, two similar actinometers were filled with the same gas mixture, and after a small quantity of air had been added to one they were both exposed to the same light. The experiment was then repeated, exchanging the actinometers. The results are recorded below:—

Experiment I.

Induction period.	Sensitiveness.
= 35 mins.	= 12.8 c.m. per min.
= 30 "	= 2.85 " "

Experiment II.

Induction period.	Sensitiveness.
= 55 mins.	= 9.9 c.m. per min.
= 46 "	= 2.2 " "

So that the presence of air certainly does not lengthen the induction period.

The Activity is due to the Condition of the Chlorine.

Having obtained the necessary information concerning the part played by the liquid in the actinometer, it became a simple matter to find out how far the chlorine is responsible for the induction period.

F. V. Bevan (*Phil. Trans.*, ccii., pp. 71—121) has recently shown that previous exposure of chlorine to light produces an increase in the rate of action, when the chlorine is mixed with hydrogen and exposed to light; but the important part played by the liquid in contact with the mixed gases was not at the time that these experiments were performed generally recognised. The difference observed by him with insulated and uninsulated chlorine was not sufficient to justify the conclusion that the main fact to be taken into account in explaining the induction period was the condition of the chlorine. Experiments performed by us in which care was taken to thoroughly induce both the chlorine and the liquid in contact with it have shown that the induction period is due to the condition of the chlorine. The results obtained in one experiment are given below. The same light was employed in both cases, and the readings were taken every two minutes.

Hydrogen + insulated chlorine.			Hydrogen + uninsulated chlorine.
Time.	Reading.	Difference.	
2 h. 2 m.	18.5	—	Induction period = 50 mins.
2 " 4 "	25.5	7.00	
2 " 6 "	35.4	9.90	
2 " 8 "	45.2	9.80	
	&c.	&c.	
The induction period = a few seconds.			
Sensitiveness = 9.80.			

Methods by which the Chlorine and its Solution can be made Active.

It has been shown that chlorine gas can be made active—

- By exposure to light.
 - By heating to a temperature of 100° C. and then cooling.
 - By the silent discharge.
- And that a solution of chlorine can be made active—
- By exposure to light.
 - By heating to 100° C.
 - By contact with active chlorine.

On the Solubility of the Activity.

The power possessed by saline and acid solutions of removing the activity from chlorine is greater than that possessed by water. No attempt has been made to measure exactly the specific absorbing power of the solution

in question, but roughly with a saturated solution of barium chloride this power is about four times as great as with pure water. The increased solubility of the activity in saline solutions proves that the salt is itself capable of absorbing the activity or of rendering the water in which it is dissolved more capable of doing so. The following experiment proves the former alternative to be correct:—Chlorine gas was shaken for about half-an-hour with a saturated aqueous solution of barium chloride in the daylight. The chlorine was then removed by evacuating the apparatus, and the water was distilled off, leaving dry crystals of barium chloride. These barium chloride crystals were immediately dissolved in an active solution of chlorine in water. A solution of practically the same strength was made by dissolving ordinary crystallised barium chloride in another portion of the active chlorine solution. The two solutions prepared in the way described were then introduced into two similar actinometers containing electrolytic gas, and the actinometers were exposed to the same light. With the actinometer which contained ordinary barium chloride, the induction period was several hours, whereas with the other it was only a few minutes. So that barium chloride can exist both in an active and in an inactive condition.

The following facts have also been experimentally demonstrated:—

1. An active aqueous solution exposed to the air in an open vessel becomes inactive exceedingly slowly.
2. Active crystals of barium chloride behave in precisely the same way as ordinary barium chloride on exposure to air for a few hours, showing that they rapidly lose their activity.
3. An active solution of chlorine either in water or in a saline solution is still active after the chlorine has been removed in a vacuum.

The Intermediate Compound Hypothesis.

Returning now to a brief consideration of the intermediate compound hypothesis, we have already seen that the reaction cannot be conceived as proceeding according to the Equations II. and III.

The assumption that the reaction proceeds according to Equation IV. is inadmissible, since it will not account for the well established induction period, which has been observed by Harden and others with a mixture of carbon monoxide and chlorine.

Equations I. and V. therefore remain as possible methods of representing the changes which take place.

The objections to I. are grounded upon relative measurements made by us of the induction period and the sensitiveness.* It has been shown that in certain circumstances the induction period becomes so long that if combination were proceeding at the ultimately attained maximum rate during the same period of time, all the electrolytic gas in the actinometer would be converted into hydrochloric acid; a result which—taken in conjunction with the law of mass—proves that all the chlorine must have been converted into the compound $\text{Cl}_2 \cdot \text{H}_2\text{O}$ before hydrochloric acid began to be formed in appreciable quantity, and this without a notable change in volume. This is in itself sufficient ground for definitely rejecting the hypothesis in question.

The objections which can be raised against a theory which postulates the formation of a catalyser of the type given under Equation V. appear to be equally conclusive.

Bunsen and Roscoe have shown, and their results have been confirmed and extended by us, that admixture of inactive with active electrolytic gas results in a mixture in which practically no combination occurs on exposure to light, but the effective action of the catalyser should be proportional to its amount—if it is not, it ceases to be by itself a satisfactory explanation. We have shown in a separate series of experiments, that reduction of pressure must result in reducing the amount of this hypothetical catalyser does not cause a new induction period.

It is difficult to avoid the conclusion that the exposure of moist chlorine to light results in the augmentation of a physical quantity closely analogous to a potential or a temperature. A mixture of active with inactive chlorine assumes, after a short time, the mean potential of the two gases, and combination with hydrogen will not take place on exposure to light. Reduction of pressure does not alter the potential, and combination with hydrogen will take place immediately under the same conditions. How such an hypothesis can be reconciled with the known facts of water catalysis must be left until a fuller account of the work can be given.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING AUGUST 31ST, 1904.

By SIR WILLIAM CROOKES, F.R.S.,
and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, September 10th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board, the results of our analyses of the 203 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from Aug. 2nd to Aug. 31st inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 203 samples examined by us during the month, all were clear, bright, and well filtered.

The rainfall at Oxford has been fairly well distributed throughout the month, and rain has fallen on nine days. The total amount recorded is 1.61 inches, and the average for August is 2.38 inches; we have, therefore, a deficit of 0.77 inch, which, if subtracted from the previous excess of 2.23 inches, leaves a total excess for the year of 1.46 inches, or 9.3 per cent above the thirty-five years' average.

Our bacteriological examinations of 384 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 382 others from special wells, standpipes, &c., making 766 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 26 samples) ..	142
New River, filtered (mean of 78 samples) ..	5
Thames, unfiltered (mean of 26 samples) ..	988
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 205 samples) ..	22
Ditto ditto highest	372
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	231
River Lea, from the East London District clear-water wells (mean of 26 samples) ..	7

Of the 300 daily samples taken from the general filter wells of the Metropolitan Water Board, eighteen samples, or 5.8 per cent, were sterile. Eleven samples, or 3.5 per cent, contained more than 100 microbes, and of these eight samples contained more than 150 microbes per c.c.

* By the sensitiveness is to be understood the rate of combination of the hydrogen and chlorine after the induction period is over.

The eleven excess samples contained an average of 186 microbes per c.c. In July seven excess samples contained an average of 177 microbes per c.c.

The above results show that the recent high degree of purity of the London waters has been well maintained during the month of August.

We are, Sir,
Your obedient Servants,

WILLIAM CROOKES.
JAMES DEWAR.

NOTICES OF BOOKS

Kritische Studien über die Vorgänge der Autoxydation.
("Critical Studies on the Processes of Autoxidation").
By C. ENGLER and J. WEISSBERG. Braunschweig:
Friedrich Vieweg und Sohn. 1904.

By the help of this monograph investigators engaged in researches on questions relating to this particular branch of chemistry will get much assistance in estimating the meaning and importance of any results they may have obtained. The book gives a critical review of the facts which have been amassed on this subject, and examines the often contradictory theories which have been put forward. The authors apply the theory of autoxidation to the interpretation of many cases, which he divides into two well differentiated classes, described as direct and indirect processes respectively, and after sections on autocatalysis and the effects of the presence of various chemical substances and physical conditions on autoxidation, he passes to the consideration of the part played by oxygen in the living organism, and to a very restricted review of the phenomena exhibited by the oxidases. In view of the comparative neglect which the theory of autoxidation processes has suffered, as seen by the lack of authoritative text-books on the subject, though numerous isolated investigations have been conducted on it, it will probably be found that this small book will supply a want.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 8, August 22, 1904.

Examination and Synthetic Preparation of certain Symmetric Cyclic Thiourides.—Emm. Pozzi-Escot.—The cyclic thiourides can be easily obtained by the action of the cyclic amines on carbon disulphide in presence of a desulphurating agent. If the amines are merely placed in contact with the carbon disulphide nothing is produced, even at the boiling-point of the mixture. It is necessary, in order to obtain good results, to dissolve the amine and the carbon disulphide in suitable solvents, and to operate in presence of a desulphurating agent. The best solvent is found to be alcohol, and the best desulphurators the caustic alkalis. The general reaction of formation is—

TRY.** By Prof. I. REMSEN. Extra Crown 8vo, 8s. 6d. net.

MACMILLAN & CO., Ltd., LONDON.

THE SIR JOHN CASS TECHNICAL INSTITUTE. JEWRY STREET, ALDGATE, E.C.

Principal—CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.

EVENING CLASSES IN CHEMISTRY, METALLURGY, PHYSICS, and MATHEMATICS.

Designed to meet the requirements of those engaged in CHEMICAL, METALLURGICAL, and ELECTRICAL INDUSTRIES, and in trades associated therewith.

Also preparation for the B.Sc. Examination of London University. Every facility for Special and Advanced Practical Work in well-equipped Laboratories, both in the Afternoon and Evening

CHEMISTRY		{ CHARLES A. KOHN, M.Sc., Ph.D., F.I.C.
PHYSICS		R. S. WILLOWS, D.Sc., M.A.
METALLURGY		C. O. BANNISTER, Assoc.R.S.M.
MATHEMATICS		G. M. K. LEGGETT, B.A.

CLASSES IN METALLURGY.

GENERAL METALLURGY.

THE METALLURGY OF GOLD, SILVER, and LEAD.

FUEL and REFRACTORIAL MATERIALS.

METALLOGRAPHY, including PYROMETRIC WORK.

ASSAYING.

ANALYTICAL CHEMISTRY,

Including ELECTROLYTIC and GAS ANALYSIS.

Each Course of Lectures will be accompanied by suitable Laboratory Work.

GLASS BLOWING.

A series of Courses of Instruction will be given during the Session by Mr. A. C. COSSOR.

SESSION began MONDAY, SEPTEMBER 26th.

The Institute is readily accessible, and near to Fenchurch Street, Liverpool Street, Broad Street, and Metropolitan Railway Stations. For details of the Classes apply at the Office of the Institute, or by letter to the PRINCIPAL.

W. H. DAVISON, M.A.,
Clerk to the Governing Body.

THE POLYTECHNIC,

309, REGENT STREET, W.

UNIVERSITY OF LONDON PREPARATION CLASSES.

Full Courses of Instruction for Matriculation,

Inter, Arts, Science, and Engineering, and Final Arts. Special Courses for Final B.Sc. in Mathematics, Physics, and Chemistry.

Examinations are held at the above Institute.

TERM commenced SEPTEMBER 16th, 1904.

Courses are so arranged that Students can do the work on Saturday and one evening per week.

Full particulars can be obtained on application to the DIRECTOR OF EDUCATION.

VOL. XC., No. 2341.

ON A METHOD OF REPRESENTING THE PROPERTIES OF ELEMENTS GRAPHICALLY BY MEANS OF CHARACTERISTIC SURFACES.

(PRELIMINARY NOTE).

By GEOFFREY MARTIN, B.Sc.

EVERY relationship which the human mind is capable of comprehending can be represented geometrically in some way or other.

If this relationship takes a form capable of being referred to number, or subjected to measurement, then it can be represented geometrically by a figure whose magnitude and shape measures numerically the degree of the relationship.

And since every geometrical locus is capable of being represented by an analytical expression, it follows that every relationship which the human mind is capable of comprehending is ultimately expressible by means of the symbols of a mathematical calculus.

In particular, the properties of an element are also relationships which are capable of being, in some way or other, portrayed geometrically.

And since these properties are, in general, subjectible to measurement, they must also be capable of being expressed quantitatively by means of an analytical expression which is the equation of the geometrical figure which pictures them.

The general problem which we propose to investigate is the construction of some geometrical figure which will quantitatively portray the chemical properties of an element.

So that to every different element there will correspond a different figure; and by merely inspecting the shape of the figure corresponding to a particular element when viewed under particular conditions of temperature and pressure, we will be able to predict quantitatively beforehand the effects the element will produce.

The equation of this figure will, in fact, bear the same relationship to that manifold of properties which is comprehended under the name of the element, as the equation of a curve bears to that manifold of geometrical points which is comprehended under the name of the curve. For just as in the former case all the geometrical properties of the curve can be deduced from the analytical expression which represents it, so in the former case all the chemical properties of an element can be deduced from the analytical expression of the geometrical locus which represents it.

In order to do this we must first determine upon what factors depend the chemical properties of an element; and then we must devise some method of representing these factors geometrically.

Now it can be proved *rigorously*—though the proof is too long to give here—that the way an element reacts depends entirely upon the forces with which it attracts other elementary atomic species. So that, knowing these forces, we know all the chemical peculiarities of the element. These are, in fact, the forces which decide with which elements a given element will combine, its degree of chemical activity, the stability of the compounds it produces, and (as I have already pointed out in the *CHEMICAL NEWS* for May 20, 1904, p. 241), to a very great extent the fusibility, volatility, solubility, hardness, &c., of the element itself and of the compounds it produces.

If, therefore, we can devise a geometrical surface which will represent the magnitude and relative intensity of the

affinities of an element, this surface may be called the *characteristic surface* of the element, since from it can be deduced all the characteristic properties of the element.

Now such a characteristic surface may be constructed for any given element in the following way:—

Let the Periodic System of the elements be plotted out on a flat surface as base as follows:—

The group numbers are plotted along o X, and the series numbers along o Y (Fig. 1).

FIG. 1.—Showing how the Position of an Element in the Periodic System is fixed by its X and Y co-ordinates, X being the Group Number, and Y the Series Number.

Then any element in the Periodic System may be denoted by a point, which is completely known when its x and y co-ordinates are known. For example, the point $x = 1, y = 2$ represents Li; $x = 5, y = 6$ represents niobium; $x = 4, y = 4$ represents Ti (see Fig. 1).

Suppose now we take any given atomic species A, whose characteristic surface it is required to construct, and measure the attractive force which it exerts on the atoms of the various elements of the Periodic System. And let us erect a perpendicular from every point in the previous diagram of a length proportional to the attractive force which A exerts on the element represented by the point.

Now imagine a surface to be described through the summits of these perpendiculars. Then this surface is the characteristic surface of the atomic species A, and can be expressed by an equation in three variables (z being the magnitude of the attractive force, $F(x, y, z) = 0$, and from this equation can be deduced (by given successive integer values to x and y) all the different affinities of the element A.

Hence, from the equation $F(x, y, z) = 0$ can be deduced all the chemical properties of the element. Moreover, the variations with the temperature, &c., in the intensities of these chemical forces will be expressed by variations in the shape of the characteristic surface. So that all the changes in the properties of an element, with the temperature, &c., can be followed by studying the changes in the shape of its characteristic surface.

The characteristic surface of an element, however, is not so simple as the above discussion might lead one to suppose. For every different element can assume a number of different valency states, in each of which it exerts a different attractive force on any given element. So that to each different valency state assumable by an element there will correspond a different affinity surface, and the collection of these different affinity surfaces may be comprised under the name of the "characteristic surface" of the element. Making, however, the assumption that any and every element can assume every grade of valence between 1 and 8—those grades of valence known to us being regarded as simply those which the element attains a condition of greatest repose or chemical equilibrium when viewed under the conditions of temperature and pressure under which we live and work, the other grades being as yet unknown—it can be shown that the total number of affinity surfaces can, by a suitable artifice, be reduced to 64, and the complete analytical expression of this collection of affinity surfaces presents a complete picture of all the chemical, and a fairly complete picture of the physical, properties of the element and its compounds, indicating, for example, precisely the relative stability of the different valency compounds it enters into with any element x, y ; how it will react, with what elements it will combine, and whether the compounds thus produced are stable or not; whether the element is metallic or non-metallic in properties, &c.

I have worked out completely the theory of these surfaces, but the method is too long to be indicated here, but will be published with the complete memoir.

There is, however, one affinity surface which is of peculiar interest, namely, that belonging to a given element when it and all the other elements of the periodic system are in that valency state in which they, under ordinary conditions of temperature or pressure, attain a condition of greatest chemical repose or equilibrium.

I have constructed such affinity surfaces (considering the element of the odd series) for the following elements:—H, Li, Na, K, Cu, Ag, Au; Mg, Zn, Cd, Hg; B, Al, Ti, C, Si, Sn, Pb; N, P, As, Sb, Bi; O, S, Se, Te; F, Cl, Br, I; and have obtained some remarkable results, which may be briefly summed up thus:—

1. The affinity surfaces of chemically similar elements are of a similar shape, and those of chemically unlike elements of a dissimilar shape—as is demanded by the theory of chemical similar elements.
2. The form of the affinity surface of a metal is diametrically opposite to that of a non-metal.

When we study the affinity surfaces of a series of elements (such as Li, Be, B, C, N, O, F, or N, P, As, Sb, Bi), which pass from a metallic to a non-metallic condition, we find that the passage of *metals* into *non-metals* is attended by a transformation of the shape of the affinity surface from the form of an irregular wave surface which has its crest over the later groups of the Periodic System (such as O and the halogen elements) into a wave surface which has its crest over elements of the early groups of the Periodic System (such as the alkali and alkaline earth metals).

And that elements of intermediate properties possess affinity surfaces of shapes intermediate between those of pronounced metals and pronounced non-metals.

The affinity surfaces of Li, Na, K are of nearly the same shape as the affinity surfaces of F, Cl, Br; except that they bear to them the same relationship that the image of an object in a mirror bears to the object—the surfaces for Li, Na, K being "right-handed"; those of F, Cl, Br are "left-handed."

3. The chemical inactivity of nitrogen is to a great extent only an apparent effect.

A study of the affinity surface of nitrogen shows that it possesses chemical affinities of a strength almost comparable to those of Na or Cl, only it differs from these elements as regards the element it exerts them on.

Thus, K expends its energies upon elements belonging to

the later groups of the Periodic System (viz., O, S, Se, and F, Cl, Br, I), but has little affinity for elements of the earlier groups (such as the alkali metals and alkaline earth metals). And *chlorine* expends its energies principally upon elements of the early groups of the Periodic System (such as the alkali metals and alkaline earth metals), but has little affinity for elements of later groups (such as O, S, Se, F, Cl, Br, I).

Nitrogen, on the other hand, expends its energies on elements of intermediate groups—principally those of Groups III., IV., and V.—but has little affinity for those of earlier or later groups (such as the alkali elements and the halogens).

For example, its combinations with boron, silicon, and phosphorus are quite remarkable by reason of their great stability—the phosphide P_3N_5 , for instance, must be heated in O gas to a temperature above that at which hard glass melts, *before* the oxygen begins to act on it!

The current belief that nitrogen is an element characterised by its chemical inertness, and by the feebleness of its chemical affinities, is therefore not entirely correct.

Cl and K appear to us to be ever so much more chemically active than nitrogen, principally because they possess powerful affinities for precisely those elements which are most prominently brought before the notice of chemists—such as the alkali elements, the halogens O, S, &c.—whereas nitrogen has the misfortune to possess but feeble affinities for such elements, but powerful affinities for such elements as Ti, Ba, B, Si, P, &c.

It should be remembered that O itself has but a feeble affinity for N, F, Cl, Br, I, &c.; and were these the only elements known, we would consider O to be quite as inactive an element as N appears to us under ordinary circumstances.

The compounds of O with Cl, for example, are characterised by their powerful explosive properties, just as are so many nitrogen compounds.

4. The affinity surface for hydrogen shows that it belongs to the alkali metal group, and not to the chlorine group of elements.
5. The point of maximum affinity shifts from F to Li as we pass from Li to F.

If we arrange in order the affinity surfaces of the elements of the first series of the Periodic System (viz., Li, Be, B, C, N, O, F) a remarkable fact becomes apparent. The affinity surfaces of the successive elements assume the appearance of successive positions of an advancing wave, whose crest, appearing on the extreme right-hand side of the diagram in the case of Li, sweeps from right to left as we pass from Li towards F, until at F the crest is on the extreme left-hand side. For example, in the case of Li the point of maximum affinity (*i.e.*, the highest point or crest of its affinity surface) is over F or Cl. Passing from Li to B the point of maximum affinity shifts towards N, BN being a body of very great stability. With C it lies over C itself, and hence the remarkable power of self-combination which C possesses. Its great involatility and its extraordinary hardness (diamond) are all evidences of the great attractive force with which C atoms cohere together.

Passing from C to N the point of maximum affinity shifts from C to B, BN being the more stable nitride N produces.

Passing from N to O, the point of maximum affinity shifts from B to Be or Li; finally passing from O to F, the point of maximum affinity shifts to Li, LiF being the most stable fluoride which F produces in this series.

The Periodic Law.

The Periodic Law shows that there is a connection between the atomic weights of elements and their properties, the connection being of such a nature that as the atomic weight increases the properties gradually alter, and then suddenly (after passing through an element of zero affinity, such as He or argon), at the end of a cycle, returns to nearly but not quite their original values. So that if the elements are arranged in the order of their atomic weights

—from H, the lightest, as unity to uranium, the heaviest, as 240—the series does not exhibit one continuous progressive modification in the physical and chemical characteristics of its several terms, but breaks up into a number of sections, in each of which the several terms present analogies with corresponding terms of the other series. Thus the whole series does not run*—

a, b, c, d, e, f, g, h, i, j, k, &c.,

but—

a, b, c, d, A, B, C, D, a, β , γ , δ , &c.

Now, the theory previously developed shows that the chemical properties of elements depend upon their attractive forces. Hence, if this theory is correct, there must be a connection between the atomic weights of elements and their attractive forces, the connection being of such a nature that as the atomic weight gradually increases the attractive forces gradually alter, and then suddenly return to nearly, but not quite, their original values—going through, as it were, cycles.

It is clear, therefore, that there must be a connection between the shape of the affinity surfaces of elements and their atomic weights, the shape gradually altering as the atomic weight alters, and then returning suddenly, at the end of a cycle, to nearly but not quite its original shape.

And this is actually the case. We find that if we arrange the elements in the order of their atomic weights, the affinity surfaces of the successive elements assume the appearance of successive positions of an advancing wave surface, whose crest, coming into the field of view on the extreme right-hand side of the diagram, gradually sweeps from right to left, altering its form continually as it passes down the field, then passes out of view on the left.

This is followed by the appearance of a new wave crest on the extreme right-hand side of the diagram, of nearly but not quite the original form, which then in its turn sweeps down the field of view and disappears, and so on; the one crest following the other like the successive waves on the sea-shore—the appearance of each new crest heralding the appearance of a new cycle of elements.

At the moment when the one crest passes out of the field of view on the left, and the second has not made its appearance on the right, we get an element of zero affinity belonging to the argon family.

As regards the elements of the odd series this is always the case. In the case of the elements of the even series this is not the case, for before the one wave crest has passed out of view, another crest has already begun to sweep down the field, and hence elements of zero affinity do not occur at all, but elements of intermediate properties such as Fe, Co, Ni; Ru, Rh, Pd; Os, Ir, Pt.

The complete memoir, with 40 plates of the affinity surfaces of 40 different elements, is now ready, and I hope to publish it in the course of this year. I am led to publish this preliminary note for various reasons, the chief among which is the fear that now my memoir has passed through several hands, I might be forestalled in the publication of these results.

University of Kiel.

REPORT OF THE COMMITTEE APPOINTED TO CONSIDER THE STANDARDISATION OF METHODS FOR THE BACTERIOSCOPIC EXAMINATION OF WATER.†

At the Congress of the Royal Institute of Public Health, held in the University of Liverpool, in July, 1903, a resolution was carried, on the motion of G. Leslie Eastes, Esq., M.B., B.Sc., that it was desirable that a committee should be appointed to consider the methods employed in the

bacterioscopic analysis of water, and, if possible, to draw up a scheme of uniform procedure for adoption in such examination, and to report to the next Congress of the Institute.

The Council of the Royal Institute of Public Health, in accordance with this resolution, appointed a committee of the following gentlemen:—

Professor Rupert Boyce, M.B., F.R.S. (chairman); the President of the Royal Institute of Public Health, Professor William R. Smith, M.D., D.Sc., F.R.S. Ed.; George M. Duncan, Esq., M.D.; G. Leslie Eastes, Esq., M.B., B.Sc.; John Eyre, Esq., M.D.; Major W. H. Horrocks, R.A.M.C., M.B., B.Sc.; William G. Savage, Esq., M.D., B.Sc.; Professor G. J. McWeeney, M.D.; Professor G. Sims Woodhead, M.D., F.R.S. Ed.; and Professor R. Tanner Hewlett, M.D., D.P.H. (Honorary Secretary).

REPORT OF THE COMMITTEE.

All the members of the Committee are in agreement that the minimal number of procedure should be:—

a. Enumeration of the bacteria present on a medium incubated at room temperature (18–22° C.).

b. Search for *Bacillus coli*, and identification and enumeration of this organism if present.

The committee regard these procedures as an irreducible minimum in the bacterioscopic analysis of water. The majority of the Committee recommend in addition:—

c. Enumeration of the bacteria present on a medium incubated at blood heat (36–38° C.).

d. Search for and enumeration of streptococci.

The Committee do not think it necessary as a routine measure to search for the *Bacillus enteritidis sporogenes*, but are agreed that in special or exceptional instances it may be advisable to look for this organism.

The Collection of the Sample.

No special precautions beyond those generally recognised are suggested for taking the sample. The samples should be collected in sterile stoppered glass bottles having a minimal capacity of 60 c.c. In special instances it may be desirable to have much larger quantities.

Unless examined within three hours of collection the sample must be ice-packed.

(The Committee recognise that under all circumstances the sooner the water is examined after collection the more reliable are the results obtained.)

Media to be Employed for Enumeration.

The choice of medium lies between distilled water gelatin, nutrient gelatin, distilled water agar, gelatin agar, and nutrient agar. The reaction of the medium is of importance.

For enumeration at room temperature any of these media may be employed, but for enumeration at blood heat an agar or gelatin agar must be used.

The Americans seem to be using an agar medium only, and although on the ground of simplicity it might be desirable to use a single medium for enumeration under all circumstances—e.g., a distilled water agar—it is felt by the Committee that gelatin media frequently give indications of value that are lacking with agar—viz., liquefaction of the medium by many organisms and the more characteristic appearance of the colonies in it; gelatin is therefore recommended.

Since with a polluted water (detection of pollution being the ultimate aim in water examination) nutrient gelatin gives a relatively larger number of colonies than distilled water gelatin, nutrient gelatin should be used when one gelatin only is employed. At the same time, it is recognised that cultures in distilled water gelatin compared with cultures in nutrient gelatin often give useful indications. Thus with an unpolluted water the number of colonies is usually relatively larger in distilled water gelatin than in nutrient gelatin; with a polluted water the converse is the case. Therefore the use of both gelatins (distilled

* The illustration is from Huxley, "Method and Results," pp. 76–77.
† From the *Journal of State Medicine*, August, 1904.

water and nutrient is desirable), sets of plates being made with each medium.

Similarly, it was felt by many members of the Committee that a comparison of the ratio of the number of organisms developing at room temperature to those developing at blood heat gives useful indications. With a pure water this ratio is generally considerably higher than 10 to 1, with a polluted water this ratio is approached, and frequently becomes 10 to 2, 10 to 3, or even less. The actual number of organisms growing at blood heat is also of considerable value apart from any question of ratio. Therefore it is suggested that plates of nutrient agar should also be employed and incubated at blood heat.

In certain instances it is true that this ratio may be unreliable. Thus with surface waters, especially in tropical countries (as pointed out by Major Horrocks) varieties of the *Bacillus fluorescens liquefaciens* and non *liquefaciens* and *Bacillus liquefaciens* may be abundant and grow well at blood heat.

Preparation and Reaction of Media for Enumeration.

a. *Distilled Water Gelatin*.—Ten per cent gelatin in distilled water, and brought to a reaction of + 10 (Eyre's scale).

b. *Nutrient Gelatin*.—Ten per cent nutrient gelatin, preferably made with meat (beef) infusion and Witte's peptone, and brought to a reaction of + 10 (Eyre's scale).

In hot weather it may be necessary to increase the percentage of gelatin.

Some members of the Committee advocate the use of meat extracts in place of meat infusion, on the score of convenience and uniformity of composition, Brand's Essence or Bovril's Essence of Meat being recommended as the best. It is the general opinion, however, that Liebig's Extract is less suitable for this purpose.

c. For enumeration of blood heat it is recommended that *nutrient agar* should be employed, being prepared with the same constituents as nutrient gelatin, but substituting 1½ per cent of powdered agar for the gelatin. Reaction + 10.

d. *Distilled Water Agar*.—Powdered agar 1½ per cent dissolved in distilled water, and brought to a reaction of + 10.

Owing to the changes which occur in the reaction of the medium on keeping, the media employed should preferably be not more than three weeks old.

Amounts to be Plated, Size of Dishes, &c.

Gelatin.—For an ordinary water amounts of 0.2, 0.3, and 0.5 c.c. may be plated in Petri dishes of not less than 10 c.m. diameter, preferably done in duplicate.

Agar.—Two plates may be made with 0.1 and 1.0 c.c., and are preferably duplicated.

In dealing with an unknown water, and in all cases of doubt, additional sets of plates should be prepared with a dilution of the water (made with sterilised tap-water) of ten or hundred fold, according to circumstances.

The amount of the medium in a plate should be 10 c.c.

The sample must be thoroughly shaken and mixed in all cases before plating.

Temperature of Incubation.

- | | | |
|---------------------|-------|-----------|
| a. Room temperature | | 18—22° C. |
| b. Blood heat | | 36—38° C. |

Counting.

Counting to be done with the naked eye, preferably in daylight, any doubtful colony being determined with the aid of a lens or low-power objective.

Time of Counting.—Gelatin plates should be counted at the end of seventy-two hours; but in all cases the plates should be inspected daily, in order that the count may be made earlier should liquefaction render this necessary.

The blood heat agar plates should be counted at the end of forty to forty-eight hours.

Search for *Bacillus Coli*.

Method.—The Committee recommend either—

a. The glucose formate broth method of Pakes.

b. The bile salt broth method of McConkey.

Incubation anaerobically at 42° C. increases the chances of success with either medium, and is strongly recommended.

It has also been suggested that the neutral-red (Grübler's) glucose broth medium may be employed.

The Committee do not regard with favour the Parietti method, or the use of carbohic acid media.

Quantity of Water to be Examined.

As a routine 50 c.c. should be the minimal quantity examined for the presence of the *Bacillus coli*, quantities from a minimum of 0.1 c.c. to a maximum of 25 c.c. being added to the tubes of culture media.

The Committee are of opinion that it is preferable to add the water directly to the tubes of culture medium, even with the larger amounts, rather than first to concentrate by filtration through a porcelain filter (the filter brushing method). The culture media recommended may be diluted with at least an equal volume of the water without interfering with their cultural properties, and large tubes or small flasks may be used for the larger amounts.

In the case of the bile salt lactose peptone water, the medium may for the larger amounts be prepared of double strength.

Isolation of *Bacillus Coli*, if present.

If indications of the presence of *Bacillus coli* be obtained in the preliminary cultivations, the organism must be isolated and identified.

This may be done by making *surface cultures* on plates of either—

- Litmus lactose agar, reaction + 10;
- Bile salt agar;
- Nutrose agar of Conradi and Drigalski; or
- Ordinary nutrient gelatin.

The best medium of all is, probably, the nutrose agar of Conradi and Drigalski. Agar media have the advantage of saving time.

Identification of, and Tests for, the *Bacillus Coli*.

Having obtained coli-like colonies on the plates made from the preliminary cultivations of the water, sub-cultures must be made in order to identify the organism. The following, at least, should be made:—

- Surface agar at 37° C. The abundant growth so obtained enables many sub-cultures and preparations to be made if required.
- Stab and surface cultures in gelatin. This may be done in the same tube.
- Litmus milk incubated at 37° C.
- Glucose litmus medium.
- Lactose litmus medium.
- Peptone water for indol reaction.

Characters of the *Bacillus Coli*.

The *Bacillus coli* is a small motile, non-sporing bacillus, growing at 37° C. as well as at room temperature. The motility is well observed in a young culture in a fluid glucose medium. It is decolourised by Gram's method of staining. It never liquefies gelatin, and the gelatin cultures should be kept for at least ten days in order to exclude a liquefying bacillus. It forms smooth, thin surface growths and colonies on gelatin, not corrugated, growing well to the bottom of the stab (facultative anaerobe).

It produces permanent acidity in milk, which is curdled within seven days at 37° C. It ferments glucose and lactose, with the production both of acid and of gas.

The typical *Bacillus coli* must conform to the above description and tests.

It generally also forms indol (best obtained in peptone water cultures), gives a thick yellowish-brown growth on

potato (greatly dependent on the character of the potato, sometimes (about 50 per cent) ferments saccharose, changes neutral red (Grübler's), and reduces nitrates, and half the gas produced by it from glucose is absorbable by KOH; and these tests, if time and opportunity permit, may be performed in addition to the foregoing.

The Committee recognise that atypical *Bacilli coli* are met with, but in the present state of our knowledge hesitate to make any suggestion with regard to their significance.

Streptococci.

The Committee consider that it is a distinct advantage to search for streptococci. They may be looked for by making hanging-drop preparations of the fluid media employed for the preliminary cultivation of the *Bacillus coli* (glucose formate broth, &c.). The presence or absence of streptococci in these tubes gives also a quantitative value to the examination, just as in the case of *Bacillus coli*, and the result obtained should be stated. The streptococci should be isolated (best carried out on nutrose agar plates), and their characters determined.

Bacillus Enteritidis Sporogenes.

As already stated, the Committee do not consider that it is essential as a routine procedure to search for the *Bacillus enteritidis sporogenes*, though in certain instances it may be of advantage to do so. A negative result in such cases is probably of more value than a positive one.

This report is the outcome of prolonged deliberations, and every point has been carefully considered and discussed by the members of the Committee.

In conclusion, the Committee suggest that if the above recommendations were to be adopted by all engaged in the bacteriological examination of water it would conduce to uniformity of results, and would render comparable the data obtained by different observers. An addendum might be added to a report on an analysis conducted on these lines, to the effect that the analysis had been carried out in conformity with the procedures recommended by the Committee of the Royal Institute of Public Health, 1904.

The Committee beg to acknowledge their great indebtedness to Prof. R. Tanner Hewlett, M.D., D.P.H., upon whom the great burden of the work of the Committee has devolved.

EFFECT OF MERCERISING ON DYE AFFINITY.

By W. P. DREAPER, F.I.C., F.C.S.

FOLLOWING my remarks on colloids and the action of dyes in my paper on "Gravity and Chemical Action" (CHEMICAL NEWS, vol. xc., p. 53), it would seem reasonable to assume that the additional affinity of mercerised cotton for dye-stuffs is due to the higher colloidal state of the fibre substance.

This action has been noticed by several observers, including Schaposchnikoff and Minajeff (*Zeit. f. Farb. und Text. Chem.*, 1903, No. 13; 1904, p. 163), Hübner and Pope (*Journ. Soc. Chem. Industry*, 1904, p. 404).

If this explanation is correct, it would follow that the ratio of colour taken up by the treated cotton and the natural fibre would be a constant one for ordinary dyes, assuming that the dyeing action is due to the higher colloid holding back a greater proportion of the dye, and that there is no additional chemical or other action between the fibre and the dye. The figures given by Schaposchnikoff and Minajeff in their articles indicate that in the majority of cases this is so. Working with such widely different substances as indigo, Diamine Blue 3 B (direct dye), and tannic acid, the ratio in each case is as 100 is to 140.

Although the authors do not seem to realise the importance of their figures, yet these figures are very in-

teresting from this point of view. For these figures indicate, so far as they go, the mechanical nature of the dyeing action in the above cases. The authors also examined the action of mercerised cotton on mordants in the same way. Here they do not indicate that the same ratio, 100—140, is obtained, but E. Knecht (*Journ. Soc. Dyers and Colourists*, 1903, p. 181) points out that their methods of estimating the results obtained are seriously at fault in this case. The absorption in this case may also be modified by the condition of the solution, &c.

The fact noted that a greater proportion of dye is required to produce the same shade in the case of the mercerised fibre is probably to be explained on physical or optical grounds, and has little to do with the direct action of the dyes as expressed by their absorption values.

The further values promised by the authors on insoluble azo-dyes, sulphide colours, and even aniline black, although necessarily of a more complicated order, should be of great interest.

This relative action of dyes on fibre material may in time afford a direct measurement of the colloidal state of the fibres in terms of their relative absorption.

From this point of view the difference between the dyeing properties of direct and ordinary dyes on cotton would be a measure of their relative colloidal properties. Mosenthal (*Journ. Soc. Chem. Industry*, vol. xliii., p. 292) has pointed out the extremely porous nature of the cuticle of the cotton fibre. It had previously been assumed that the dyeing action of the cotton fibre (Crum, *Journ. Chem. Soc.*, vol. i., p. 409) was due to capillary action, the cuticle being non-porous. Still, arguing from the above point of view, the "mesh" of the cotton fibre would be too large to hold the ordinary acid dyes, but able to hold or retain the tetrazo or higher colloid dyes. It may be pointed out in confirmation of this view that artificially prepared filaments of cellulose (artificial silk), which without much alteration in chemical composition are in a highly colloidal state, easily retain ordinary acid colours.

It is of course possible that when once a dye is retained by this colloid action that solid solution, or even condensation, may play some part in the action.

When Cross and Bevan (*Journ. Soc. Chem. Industry*, vol. xiii., p. 354) criticised Dr. Weber's theoretical conclusions on the ground that he assumed a one-sided penetrability, they overlooked the possibility of some such retaining action on the part of the fibre. This would produce the dyeing action.

Perhaps the difference between the fastness of ingrain dyes when dyed direct to those "developed" or dyed ingrain (Dreaper, *Journ. Soc. Chem. Industry*, vol. xiii., p. 95) may be due to the fact that in direct dyeing we only get this colloid precipitating action. In the case where the dye is actually developed or produced in the fibre itself, we may be working under such conditions that actual or at least a more perfect solid solution obtains. This would agree with the fact I brought forward, that the dyes are still fast against boiling out after the phenolic dyed samples are treated with dilute caustic alkali, in which solution the dye is very soluble. The alternative idea put forward by Prof. Green in the discussion following my paper (*Ibid.*), that the ingrain dyed sample was fast because of the increased size of the aggregates formed in the fibre space, does not explain why the dye is still fast after the above treatment. If, in place of this action, we had solid solution, the action of the alkali would probably be as non-effective as it is in practice. The idea is therefore put forward that the increased affinity of mercerised cotton for dye-stuffs is a measure of the increased colloidity of the fibre.

In conclusion I would put forward a plea for greater accuracy of detail in the experiments carried out in connection with the theory of dyeing. The discussion carried on at the present time seems to turn almost entirely on the mistakes of individual experimenters. Until experiments are conducted on closer and more careful lines we shall remain in the present state of uncertainty.

THE PRODUCTIONS OF MAGNETIC ALLOYS
FROM NON-MAGNETIC METALS.*

By R. A. HADFIELD.

It is thought that the following description of the Heusler alloys may be of interest to the Section.

Having some years ago produced a non-magnetic iron alloy, known as "manganese steel," I was much interested in learning from Dr. Heusler that, with the same metal (manganese) which had enabled me to obtain a practically non-magnetic iron alloy, it had been found possible to produce a magnetic copper alloy.

I have had communications with Dr. F. Heusler, who has given me much interesting information regarding these special alloys, and have myself also produced some of them.

It is, of course, well known that the metals copper, aluminium, and manganese are non-magnetic. It is therefore, to say the least, surprising to find that, combined in certain proportions, they produce an alloy having quite considerable magnetic properties.

It may be first mentioned that no combination of copper with aluminium produces a magnetic alloy; the peculiar change noticed, therefore, must be ascribed entirely to the presence of the metal manganese—the same metal which, in manganese steel, produces the profound change in iron, converting it from its well-known magnetic to non-magnetic condition.

As it was thought that perhaps the metal manganese under certain conditions might show some reversibility, as is the case with certain iron-nickel alloys, which, whilst being non-magnetic at ordinary temperatures, become magnetic at low temperatures, -60° to -80° C., Sir James Dewar himself submitted to the temperature of liquid air the manganese metal I used in producing the alloy exhibited. No change was found to occur; the metal remained as non-magnetic as at ordinary temperatures. This, of course, under the same test was found to be the case with the copper and aluminium used in my experiments.

The alloy exhibited contained 60 per cent copper, 25 to 27 per cent manganese, and 12 per cent of aluminium. The manganese metal used contained about 92 per cent of manganese, the rest being 6 to 7 per cent of silicon, 0.5 to 1 per cent of carbon, and probably 0.50 per cent of iron. But Dr. Heusler has shown that with absolutely no iron present the magnetic qualities are exactly the same.

Another very curious point is that, whilst it must be the manganese which confers the magnetic properties, the "reversibility," so to speak, is brought about by the aluminium.

For example, with the manganese fairly constant (25 to 28 per cent) and the aluminium varying from 3 to 14 per cent, the magnetisability with 3 per cent is nil, 5 per cent confers a little, 10 per cent is still more, the maximum being reached with 14 per cent aluminium.

Specimen number.	Analysis (per cent).		H = (magnetising force).			
	Mn.	Al.	20.	40.	100.	150.
34.	28	3.6	Nonmagnetisable.			
35.	28	5.7	Very slightly magnetisable.			
36.	26	9.6	2220	2670	3200	3470
32.	26	14.6	4500	4850	5380	5550
33.	25	13.8	3580	4075	4645	4900

B =

From the above list it will be seen that Dr. Heusler finds the magnetisability of the alloy will increase with an increased percentage of aluminium, the maximum for any stated percentage of the manganese being attained when the aluminium percentage amounts to (roughly) one-half of the percentage of manganese; or, in other words, when the alloy contains one atom of aluminium to one atom of manganese.

It may be added that the alloy exhibited is unfortunately very brittle, and all attempts to forge it cold or hot at various temperatures, even only at dull red, have been unsuccessful.

It may be further added that the alloy is faintly magnetic immediately after casting, but becomes non-magnetic when heated to about 170° and quenched in cold water.

But by continued heating to about 80 – 150° magnetisability reappears and in an intensified degree. The unstable magnetic condition becomes stable.

Other metals may be introduced without causing the alloy to lose its magnetic properties.

For example, lead may be introduced. The alloy is then more fusible, the transformation-point is lowered, and, under suitable heat treatment conditions, the magnetisability is even increased. Tin is another example; 10 per cent gives magnetisability, the maximum being obtained with 21 to 22 per cent of tin to 30 per cent of manganese.

Alloys of antimony and manganese, no copper being present, are also magnetic.

THE ACTION OF CERTAIN GASES ON
GLASS IN THE NEIGHBOURHOOD OF HEATED
METALS.*

By G. T. BEILBY.

In a former paper (*British Association Report*, Southport, 1903) I described the formation of halos around pieces of metal-foil on glass plates when these are heated to a sufficient temperature in the presence of the products of combustion of coal-gas and air. The form of the halos themselves, as well as the formation of corresponding images of the metal on glass plates placed at a little distance above the heated metal, suggested that the effects were produced either directly or indirectly by particles thrown off from the hot metal. The halos and images were found to consist of the decomposition products of the glass itself, silica and soluble alkaline salts, and the chemical agent in the decomposition was seen to be one or other of the gases of the surrounding atmosphere. Two matters for further inquiry therefore presented themselves:—(1) To what chemical agent is the decomposition of the glass due? And (2) what is the cause of the localisation of this decomposition in the immediate neighbourhood of the hot metal as shown in the formation of halos or images?

The first of these questions was settled by a series of experiments in which glass slips with small pieces of platinum-foil laid upon them were heated in a glass tube through which specially prepared gases were led. The tube, of course, served to completely exclude the products of combustion given out by the heating burner. The glass slips were heated to 500 – 600° , while a current of gas was passed through the tube at the rate of a litre per hour. After heating for an hour the glass slips were allowed to cool down slowly to the atmospheric temperature, and were then examined and compared with each other, and with similar slips which had been heated on a hot plate with free access of the products of combustion of coal-gas and air.

Experiment 1.—With air which had been freed from CO_2 and other acid gases, and then dried by passing it over CaCl_2 . No halo was visible on the slip till it was breathed on, when a very faint but distinct halo appeared.

Experiment 2.—With air which had been freed from CO_2 and then saturated with water vapour by bubbling it through water at 50° . A distinct halo was produced, but the decomposition of the glass had been very much less energetic than it would have been in the presence of combustion products. From the marked effect produced by the addition of water vapour it seems probable that if the air in Experiment 1 had been more perfectly dried, not even the faint halo would have been produced.

* Read before the British Association (Section A), Cambridge Meeting, 1904.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

Experiment 3.—With CO_2 dried to the same extent as the air in Experiment 1. No halo was visible till the slip was breathed on, when an even fainter halo than that observed in Experiment 1 appeared.

Experiment 4.—With air which had been shaken up with a saturated aqueous solution of SO_2 , and afterwards dried as in Experiment 1. A well-defined halo appeared, comparable in distinctness with those produced in the presence of the products of combustion.

When these halos are breathed on so that a film of moisture condenses momentarily on the surface of the glass and then evaporates, the salts which have been dissolved by the water re-crystallise and become markedly separated from the insoluble films of silica. The microscopic appearance of this crystallisation correspond with that of sodium sulphate, and the solution of these salts gives a precipitate of barium sulphate. It may therefore be concluded that the decomposition of the glass is due to the action of sulphuric anhydride which has been formed by the union of SO_2 with O.

Experiment 5.—The same mixture of air and SO_2 was bubbled through an aqueous solution of SO_2 maintained at 50° , thus raising the proportion of SO_2 and H_2O in the gas.

The entire surface of the glass slip, as well as that of the heated part of the interior of the glass tube, was now covered with a white film of decomposed glass, the spot on which the platinum-foil had lain being marked out by its being less thickly covered with the white film. In this case it was evident that the increased proportions of SO_2 and H_2O in the gas had enabled the combination to take place with such freedom that the accelerating action of the hot metal was now relatively small.

Experiment 6.—A portion near the centre of a glass tube was heated to about 600° . A fine glass tube containing a little sulphuric acid was placed in the tube sufficiently near the heated part to volatilise the sulphuric acid slowly. A slow current of air was passed through the heated tube in the direction which enabled it to carry the SO_3 and H_2O evolved by the acid through the heated portion.

In a few minutes the interior surface of the heated portion of the tube was covered with a white film of decomposed glass to all appearance identical with the films developed in Experiment 5.

This experiment further confirms the conclusion that the attack on the heated glass is made by SO_3 .

The familiar phenomenon of the formation of a dull white film on the surface of glass vessels, which have been heated above a certain temperature in gas furnaces or muffles, evidently results from this action of SO_3 on the silicates of the glass. When the action has been slight the entire film may be washed off, leaving a perfectly polished surface, but after long continued or severe action the surface of the glass is permanently roughened. This appearance is often mistaken for devitrification of the glass, but microscopic examination shows that the roughened surface is not crystalline, but finely granular, and very similar to that produced by the action of a mixture of gaseous hydrofluoric acid and air.

Experiments 1 and 2 show that moist air also attacks and decomposes glass, but this action is so slight that it has only been observed in the immediate neighbourhood of the hot platinum.

The second question proposed at the outset of this paper was:—What is the cause of the localisation of the decomposition of the glass in the immediate neighbourhood of the hot metal as shown by the formation of halos or images? The preceding observations having shown that the active chemical agent in the production of these appearances is sulphur trioxide, the suggestion naturally occurs that it is the presence of the hot metal which determines the formation of SO_3 by the union of SO_2 with O. The influence of solid catalysts in bringing about this synthesis is well known, and the subject might therefore have been dismissed without further experiment or discussion had it not been that the opportunity appeared to be a favourable one for obtaining information as to whether the action takes place

wholly on the surface of the hot metal, or whether it also occurs in the atmosphere surrounding the metal.

If the SO_3 molecules are formed on the surface of the metal, they ought at once to diffuse into the surrounding atmosphere, being quickly separated from their fellow molecules among the vastly preponderating number of molecules of the other gases composing that atmosphere.

Taking the coal-gas used as of average purity as regards sulphur, the proportion of SO_3 present in the atmosphere could not exceed 1/50,000. But when the forms and disposition of the halos and images around and above the metal are studied, it is seen that they do not correspond very satisfactorily with the above views as to the immediate diffusion of the SO_3 molecules in the surrounding atmosphere. The halos and images are to some extent permanent records of the course followed by these molecules, and as such they distinctly suggest that the molecules of SO_3 have travelled together from the metal surface, and that they have remained in company to a much greater extent than might have been expected had their movements been simply determined by molecular diffusion. The appearances rather suggest that the agent which caused them was in the form of a cloud of projectiles, some of which were carried up to the under surface of the covering glass which they attacked, producing the image, while the greater number, falling short of this, fell back on the surface of the lower glass slip, producing the halo around the metal.

The disintegration of hot platinum has been recently studied by Holborn and Austin (*Phil. Mag.*, April, 1904, p. 388), who have found that at temperatures above 1150° the loss of weight from a platinum surface of 150 sq. m.m. in thirty minutes was quite weighable. But from the rate of decrease of this loss with falling temperature, it is evident that at the temperatures used in my experiments, 500 – 600° , the loss over this short period would be quite unweighable. Nevertheless, taking these observations in connection with those of Richardson (*Phil. Mag.*, July, 1903, p. 80) on the "Positive Ionisation produced by Hot Platinum in Air at Various Pressures," it appears not improbable that there is an actual if slow disintegration at the lower temperature, in which case the particles or ions thrown off might play the double part of projectiles and nuclei.

Experiments have been made on sweeping the nuclei forward from the hot platinum with pure air and with pure nitrogen; these gases being afterwards allowed to intermingle with the products of combustion in contact with a hot glass surface. In neither case was the action on the glass sufficiently distinct to enable it to be definitely attributed to the nuclei carried over from the platinum. The products of combustion themselves appear to carry with them sufficient nuclei to determine the formation of SO_3 in sufficient quantity to produce a slight general attack all over the heated glass surface. This attack effectually masks the slighter effects which result from any nuclei which may be carried over from the platinum in the above experiment.

It cannot be claimed for these observations that they give a conclusive answer to the question, "What is the cause of the localisation of the decomposition in the neighbourhood of the hot metal?" but they certainly do not give a final negative to the suggestion that some part of this effect is due to ionisation produced by the hot metal.

Synthesis of Estragol and the Aromatic Derivatives with Non-saturated Chain.—M. Tiffeneau.—The synthesis of estragol, which the author realised by means of the magnesium derivatives, has since been published by other chemists. His results, however, show that allyl iodide and bromide react on the organo-magnesium compounds, even in the cold, whilst the other non-saturated halogen derivatives only unite after almost complete elimination of the ether, and at a temperature of 100° or more.—*Comptes Rendus*, cxxxix., No. 10.

A REACTION FOR KETO-HEXOSES.*

By HENRY J. HORSTMAN FENTON, F.R.S.

By oxidation of lævulose, cane-sugar, inulin, or sorbose in presence of ferrous iron at about 90–100°, and heating the resulting solution with phenylhydrazine-*p*-sulphonic acid, a compound is obtained which dyes silk a rich brownish pink colour, which is remarkably stable and permanent. This reaction appears to be especially characteristic of keto-hexoses or substances which yield them on hydrolysis, and is given by dextrose, milk-sugar, maltose, or starch only to a limited extent or not at all.

A COLOUR REACTION FOR METHYLFURFURAL AND ITS DERIVATIVES.*

By H. J. H. FENTON, F.R.S., and J. P. MILLINGTON, B.A.

WHEN bromomethyl-furfural is heated with dimethylaniline and a dehydrating agent, such as phosphorus oxychloride, zinc chloride, or dry oxalic acid, an intensely blue-coloured compound is obtained. This reaction is extremely sensitive, and is given by bromo-, chloro-, iodo-, or acetoxy-methylfurfural, and by methylfurfural itself, but not by the condensation products previously described (Fenton and Gostling, *Trans. Chem. Soc.*, 1899, 423; 1901, 807). As a dye the blue colour appears to be very permanent in the dark, but slowly fades in sunlight.

THE ACTION OF ORGANIC BASES ON OLEFINIC KETONIC COMPOUNDS.*

By S. RUHEMANN and E. R. WATSON.

THE authors have continued their investigations of the behaviour of unsaturated ketonic compounds (*cf. Trans. Chem. Soc.*, 1904, lxxv., 466), especially of benzylidene-acetylacetone, towards organic bases, and have isolated several additive compounds which are thus formed, *e.g.*, with *m*-toluidine, *p*-toluidine, *m*-chloroaniline, *p*-chloroaniline, *β*-naphthylamine. These compounds, on heating, suffer the following decomposition:—

In some cases the additive compounds cannot be isolated, since they are decomposed at once according to the above equation. Of interest is the fact that neither *o*-toluidine nor *α*-naphthylamine combine additively with benzylidene-acetylacetone. *o*-Substituted benzenoid bases, therefore, seem not to react with the diketone. This conclusion is supported by the fact that piperidine readily forms an additive product with benzylideneacetylacetone, but tetrahydroquinoline does not.

The study of piperidobenzylacetylacetone,—

the additive compound formed from benzylideneacetylacetone and piperidine, has proved of the greatest interest as throwing light on the catalytic action of piperidine and other secondary bases in the condensations of aldehydes and ketones which have been elaborated by Knoevenagel and his pupils.

Taking the formation of benzylidene-*bis*-acetylacetone as example, the authors arrive at the view that the reaction is to be expressed thus:—

1. $\text{C}_6\text{H}_5\cdot\text{CH}(\text{CO}\cdot\text{CO}\cdot\text{CH}_3)_2 + \text{C}_5\text{H}_{10}\cdot\text{NH} = \text{C}_6\text{H}_5\cdot\text{CH}(\text{N}\cdot\text{C}_5\text{H}_{10})\cdot\text{CH}(\text{CO}\cdot\text{CH}_3)_2.$
2. $\text{C}_6\text{H}_5\cdot\text{CH}(\text{N}\cdot\text{C}_5\text{H}_{10})\cdot\text{CH}(\text{CO}\cdot\text{CH}_3)_2 + \text{CH}_2(\text{CO}\cdot\text{CH}_3)_2 = \text{C}_6\text{H}_5\cdot\text{CH}(\text{CH}_2\text{CO}\cdot\text{CH}_3)_2 + 2\text{H}_2\text{O}.$

* Read before the British Association (Section B), Cambridge Meeting, 1904.

Also Knoevenagel and Faber's observation (*Ber.*, xxxi., 2773), that ethyl benzylideneacetoacetate in the presence of diethylamine yields ethyl benzylidene-*bis*-acetoacetate, has found a ready explanation. The fact that piperidobenzylacetylacetone, on treatment with water, yields benzaldehyde and benzylidene-*bis*-acetylacetone indicates that the formation of the latter substance is preceded by the production of an additive compound of the unsaturated ketone with the bases.

THE DECOMPOSITION AND SYNTHESIS OF AMMONIA.*

By EDGAR PHILIP PERMAN.

It is well known that on heating ammonia a large proportion of it is decomposed, and it has been assumed by many chemists that the mixture then comes into chemical equilibrium: some experiments recently carried out by Mr. G. A. S. Atkinson and myself seem to disprove the existence of any equilibrium in the case.

Decomposition of Ammonia by Heat.—In a recent paper (*Proc. Roy. Soc.*, lxxiv., 110) it was shown, from observations on the rate of decomposition of ammonia heated in a porcelain globe, that there is no equilibrium until complete (or nearly complete) decomposition has taken place, and that the reaction is mono-molecular.

Direct Synthesis of Ammonia by Heat.—To solve the question of equilibrium, it was thought better to attempt to reach the equilibrium point, if any, by synthesis. A mixture of nitrogen and hydrogen (1:3) was passed slowly through a red-hot glass tube into dilute acid; the solution was then made alkaline, and tested for ammonia by Nessler's solution; *not a trace was found*. The result was similar when the tube was packed with broken porcelain. If, however, the mixture was passed over red-hot iron (or many other metals) or over asbestos, pumice, or clay tobacco-pipe stems, traces of ammonia were formed. These last-named substances contain iron, and it is concluded that there is no combination of the nitrogen and hydrogen unless there is some catalysing agent present.

Decomposition and Synthesis of Ammonia by Electricity.—Traces of ammonia were formed on sparking a mixture of nitrogen and hydrogen, and the gases came into equilibrium (with the apparatus used) in about thirty minutes. Approximately the same equilibrium point was reached on decomposing ammonia by sparking, but when the volume was kept constant many hours' sparking were required to reach that point.

ON THE PRODUCTS OBTAINED BY THE ACTION OF TERTIARY BASES ON SOME ACID CHLORIDES.*

By Professor EDGAR WEDEKIND.

THE author has previously shown (*Annalen*, cccxviii., 99; cccxxiii., 257) that, in spite of the violent reaction which occurs between the chlorides of powerful acids and strong tertiary bases, no quaternary salt of the type $\text{R}_3\text{N}\cdot\text{CO}\cdot\text{Cl}$ is produced, but that the hydrochloride of the tertiary amine, $\text{R}_3\text{N}\cdot\text{H}\cdot\text{Cl}$, is obtained in quantitative yield. This fact is in so far of importance in connection with the stereochemistry of nitrogen, as it indicates the reluctance of the trivalent nitrogen atom to take up two acidic or negative groups; the trivalent nitrogen atom exhibits a kind of striving to assume the most stable condition—that, namely, of which ammonium chloride is the type.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

The question at once arises in connection with the above reaction as to what becomes of the residue of the acid chloride molecule; the solution of this problem presented extraordinary experimental difficulties, but its study has led to the discovery of several interesting facts which may here be briefly mentioned. The author has already shown that by the action of acetyl chloride on triethylamine, pyridine, &c., dehydracetic acid is produced (*Annalen*, cccxxiii., 247); in this reaction four molecules of each component take part in accordance with the equation—

but when the acetic chloride is replaced by propionyl, phenylacetic, or hydrocinnamic chloride, products are obtained which have only three times the molecular weight of the hypothetical substance which must be supposed to be first formed by the splitting off of hydrogen chloride from the *one* molecule of the acid chloride. Thus, the condensation product from propionic chloride, $\text{CH}_3\cdot\text{CH}_2\cdot\text{CO}\cdot\text{Cl}$, has the empirical formula $\text{C}_9\text{H}_{14}\text{O}_3$ or $3(\text{C}_3\text{H}_5\text{O})$, and that from phenylacetic chloride, $\text{C}_6\text{H}_5\cdot\text{CH}_2\cdot\text{CO}\cdot\text{Cl}$, corresponds to the formula $\text{C}_{24}\text{H}_{18}\text{O}_3$ or $3(\text{C}_8\text{H}_6\text{O})$.

The latter substance proved to be fairly easily obtainable, and the first supposition that it might be a phloroglucinol derivative—the symmetrical triphenylphloroglucinol—was found untenable, because the material can under no conditions be reduced to triphenylbenzene, and is relatively very stable even in alkaline solutions. The new compound shows simultaneously the behaviour of a lactone, a monoketone, and a primary alcohol; thus it gives with soda a monosodio-derivative, with hydroxylamine a monoxime, with acetic chloride a monoacetyl compound, and with benzoyl chloride a monobenzoyl derivative. On treating it with ammonia under pressure it yields a very stable pyridine derivative, and this reaction shows it to be a simple homologue of pyronone. (The previously known pyronone compounds contain, like dehydracetic acid, a carboxyl group in the side chain).

The mechanism of the reaction by which the substance is formed (compare J. N. Collie, *Trans. Chem. Soc.*, lxxvii., 971) would seem to be that three molecules of the acid chloride first condense with evolution of two molecules of hydrogen chloride, yielding the chloride of an α -diketonic acid in accordance with the following scheme:—

This hypothetical chloride then undergoes total or partial conversion into an enolic form, from which by subsequent loss of hydrogen chloride, in which the hydroxyl group is involved, the closed pyronone ring is formed—

Since this pyronone derivative differs from those previously studied in that it gives an oxime as well as a monobenzoyl-derivative, it must be regarded as tautomeric in that it can assume the above ketonic form as well as the following enolic or hydroxylactonic constitution:—

The latter formula naturally gives rise to the acidic

derivatives. The remarkable power which the carbonyl group in the closed ring possesses of reacting with hydroxylamine must be attributed to the multiplication of unsaturated groups in the molecule, namely, to the presence of two phenyl groups and two double bonds in the closed chain.

As was to be expected from the known behaviour of pyrone or pyronone compounds, the action of ammonia gives benzylidiphenyldihydroxypyridine—

Lastly, it may be mentioned that the author has made a remarkable observation upon the interaction of isobutyric chloride with tertiary amines; in this reaction an extremely volatile substance crystallising in colourless needles and having an odour of menthol and camphor is obtained. This product is formed by the condensation of only two molecules of the acid chloride, and is not a pyronone derivative but a diketone; it is in all probability a tetramethylene derivative from which the author hopes to prepare the parent hydrocarbon.

SAPONARIN:

A GLUCOSIDE COLOURED BLUE BY IODINE.*

By G. BARGER.

THE substance known to botanists as "soluble starch," and occurring in the leaf epidermis of a number of plants, has been isolated from *Saponaria officinalis* at the suggestion of Professor L. Errera, of Brussels; it is a glucoside, and has been named *saponarin*. The substance is obtained pure in the shape of minute needles by a special method of crystallisation from mixtures of pyridine and water. Saponarin is insoluble in water and all ordinary organic solvents, but readily soluble in dilute alkalis and in pyridine; it melts at 231° with decomposition. The solution in alkalis is intensely yellow, and when acidified the substance remains for a long time in a state of pseudo-solution; in this condition it gives an intense blue or violet colouration with iodine dissolved in potassium iodide solution.

The air-dried crystals of saponarin lose water when heated or when left *in vacuo* over sulphuric acid. The dried substance is extremely hygroscopic, and, if left in the balance case for an hour or so, takes up quantitatively the water it had previously given off. For combustions it was dried *in vacuo* till of constant weight, and the boat containing it was then placed in a stoppered weighing tube. The mean of five analyses of the substance dried in this way gave—

C = 53.75 per cent, H = 5.16 per cent.

For the molecular weight determination pyridine was the only available solvent. The microscopic method was the most convenient, and gave the following result:—

A solution of 0.299 grm. in 2.96 grms. of pyridine was isotonic with a benzil solution of 0.23 mols. Hence M = 436.

The two possible formulae for saponarin are:—

$\text{C}_{19}\text{H}_{22}\text{O}_{11}$, requiring C 53.52, H 5.21, M 427

and—

$\text{C}_{21}\text{H}_{24}\text{O}_{12}$, requiring C 53.85, H 5.13, M = 468.

Of these the second is considered the more probable, but a definite choice cannot be made till the decomposition products of the substance have been studied more fully. On boiling saponarin with mineral acids it is hydrolysed,

* Read before the British Association (Section D), Cambridge Meeting, 1904.

and a yellow solution is formed, from which glucose was separated as phenyl glucosazaine. Unless the solution be dilute, a second product of hydrolysis separates as a thick yellow oil, which has not yet been obtained crystalline. The name *saponaretin* is suggested for it, and it is scarcely soluble in water, but dissolves in alkalis and in pyridine; it closely resembles the parent substance, but does not give the reaction with iodine. From dilute solutions saponaretin separates in the solid state, either amorphous or in the form of imperfect whetstone-shaped crystals. It has not yet been obtained quite pure, but seems to be mixed with another substance which crystallises from alcohol in glistening plates.

The formula of the latter substance has not been definitely fixed owing to want of material, but it seems to be a hydrate of saponaretin.

Saponaretin is in all probability closely allied to the flavones. When fused with potash it yields β -oxybenzoic acid, and a red solution which gives the phloroglucin reaction with pinewood. Phloroglucin itself could, however, not be isolated.

The blue substance formed from iodine and saponarin exhibits a close analogy with that formed from iodine and starch. Its composition varies considerably, and it is another example of the absorption of iodine by a substance in pseudo-solution. The blue substance has been obtained in the crystalline state, but must nevertheless be regarded as a mixture and not as a chemical compound.

LUTES.*

By SAMUEL S. SADTLER.

The subject of plastic cements used to secure joints in vessels and connections (generally for temporary purposes), has been rather neglected in the chemical literature.

The success or failure of processes has very seldom depended upon the choice of satisfactory lutes, but great annoyance has been experienced in chemical works and manufacturing places where only unsuitable compounds have been found to seal apertures in nitric acid, chlorine, hydrogen sulphide, and illuminating gas apparatus, and frequently considerable damage to property and loss of life has resulted.

I have therefore thought it advisable to bring together under the one title such formulae as I know to be reliable, or have reasonable grounds for believing so, and hope they may be useful to others for laboratory or works' use.

The majority of these cements are useful for purposes of preventing the escape of inert gases, and others are suitable for more or less special purposes, where corrosive gases, &c., come in contact with them. Many of them had to be put down from memory, and therefore the product obtained in their use may be a little too stiff or too thin, but such deficiencies could be easily regulated.

Lutes always consist of a menstruum and dissolved or suspended solids, and they must not be attacked by the gases and liquids coming in contact with them. In some cases the constituents of the lute react to form a more strongly adhering mass.

The conditions of application are, in brief:—

- a. Heating the composition to make it plastic until firmly fixed in place.
- b. Heating the surfaces.
- c. Applying the lute with water or a volatile solvent, which is allowed to volatilise.
- d. Moistening the surfaces with water, oil, &c. (the menstruum of the lute itself).
- e. Applying the lute in workable condition, and the setting taking place by chemical reactions.
- f. Setting by hydration.
- g. Setting by oxidation.

These principles will be found to cover nearly all cases. Joints should not be ill-fitting, depending upon the lute to do what the pipes or other parts of the apparatus should do. In most cases one part of the fitting should overlap the other, so as to make a small amount of the lute effective and to keep the parts of the apparatus rigid, as a luted joint is not supposed to be a particularly strong one, but rather one quickly applied, effective while in place, and easily removed.

Very moderate amounts of the lute should be used, as large amounts are likely to develop cracks, be rubbed off, &c.

A classification may be given as follows:—

- I. Plaster-of-Paris.
- II. Hydraulic cement.
- III. Clay.
- IV. Lime.
- V. Asphalt and pitch.
- VI. Resin.
- VII. Rubber.
- VIII. Linseed oil.
- IX. Casein and albumen.
- X. Silicates of soda and oxychloride cements.
- XI. Flour and starch.
- XII. Miscellaneous, including core compounds.

I. Plaster-of-Paris.

Plaster-of-Paris is, of course, often used alone as a paste, which quickly solidifies, for gas and wood distillation retorts, &c., and similar places where quickness of setting is requisite. It is more often, however, used with some fibrous material to give it greater strength. Asbestos is the most commonly used material of these, as it will stand a high temperature. When that is not so important, straw, plush trimmings, hair, &c., are used as binders, while broken stone, glass, and various mineral substances are used as fillers, but they do not add anything to the strength. These lutes seem to be particularly suitable for oil vapours and hydrocarbon gases.

Formulae:—1. Plaster and water.

2. " (wet) and asbestos.
3. " " " straw.
4. " " " plush trimmings.
5. " " " hair.
6. " " " broken stone, &c.

II. Hydraulic Cement.

Cement is used either alone or with sand, asbestos, &c., and I have been informed that these lutes are suitable for nitric acid. When used with substances such as resin or sulphur, it is probably employed because it is in such a fine state of division and used as a filler, and not because of any powers of setting by hydration.

Formulae:—1. Cement (neat).

2. " and asbestos.
3. " and sand.

III. Clay.

This most frequently enters into the composition of lutes as a filler, but even then the very finely-divided condition of certain grades renders it valuable, as it gives body to a liquid, such as linseed oil, which, unless stiffened, would be pervious to a gas, the clay in all cases being neutral. Thus, for luting pipes carrying chlorine, a stiff paste of clay and molasses has been suggested by Theo. Köller in *Die Surrogate*, but I cannot recommend it, as it soon gives way.

Formulae:—1. Clay and linseed oil.

2. Same, using fire-clay.
3. Clay and molasses.
1. Is suitable for steam, &c.,
2. For chlorine, and
3. For oil vapours,

* From the *Journal of the Franklin Institute*, clviii., No. 5.

IV. Lime.

Lime is used in the old lute known as putty, which consists of caustic lime and linseed oil. Frequently the lime is replaced by chalk and china-clay, but the lime should be, in part at least, caustic, so as to form a certain amount of lime soap. Lime is also used in silicate and casein compositions, which are very strong and useful, but will be described elsewhere.

Formula:—1. Lime and boiled oil to stiff mass.

2. Clay, &c., " "

V. Asphalt and Pitch.

These substances are used in lutes somewhat interchangeably. As a rule, pitch makes the stronger lutes. Tar is sometimes used, but, because of the light oils and (frequently) water contained, it is not as good as either of the others.

Asphalt dissolved in benzol is very useful for uniting glass for photographic, microscopical, and other uses. Also for coating wood, concrete, &c., where the melted asphalt would be too thick to cover well. Benzol is the cheapest solvent that is satisfactory for this purpose, as the only one that is cheaper would be a petroleum naphtha, and it does not dissolve all the constituents of the asphalt. For waterproofing wood, brick, concrete, &c., melted asphalt alone is much used, but when a little paraffin is added it improves its waterproofing qualities, and in particular cases boiled oil is also added to advantage.

Parts.

Formula:—1. Refined lake asphalt.

2. Asphalt	4
Paraffin	1
3. Asphalt	10
Paraffin	2
Boiled oil	1

Any of these may be thinned with hot benzol or toluol. Toluol is less volatile than benzol and about as cheap, if not cheaper, the straw-coloured grades being about 24 cents per gallon.

Examples of so-called "Stone Cement" are:—

	Parts.
4. Pitch	8
Resin	6
Wax	1
Plaster	$\frac{1}{2}$ to $\frac{1}{4}$
5. Pitch	8
Resin	7
Sulphur	2
Stone powder	1

These compositions are used to unite slate slabs and stoneware for domestic, engineering, and chemical purposes. Various resin and pitch mixtures are used for these purposes, and the proportions of these two ingredients are determined by the consistency desired. Sulphur and stone powder are added to prevent the formation of cracks; sulphur acting chemically and stone powder mechanically. Where the lute would come in contact with acid or vapours of the same, limestone should not be the powder used, otherwise it is about the best. Wax is a useful ingredient to keep the composition from getting brittle with age.

A class of lutes under this general grouping that are much used are so-called "Marine Glues." They must be tough and elastic. When used for caulking on a vessel they must expand and contract with the temperature, and not crack or come loose.

Parts.

Formula:—6. Pitch	3
Shellac	2
Pure crude rubber	1
7. Pitch	1
Shellac	1
Rubber substitute	1

These are used by melting over a burner.

(To be continued).

THE CHEMICAL NEWS.

VOL. XC., No. 2342.

THE ORIGIN OF RADIUM.*

By HERBERT N. McCOY.

THERE seems to be a tendency among chemists to divide radio-active substances into two classes. The permanently active substances, like uranium, thorium, and radium, belong to the first class, and those substances like uranium X, thorium X, the radium emanation, and polonium, whose activity is only temporary, to the second. The activity of the latter class disappears in some cases in a few minutes, and in others in the course of some months. In such cases it is supposed that the loss of activity represents the chemical decomposition or transformation of the active material. Some of the temporarily radio-active substances pass through two or more consecutive stages during their period of activity. Thus the radium emanation gives rise to the emanation X (formerly called "excited activity"), and thorium X gives rise to the thorium emanation. The different stages are experimentally distinguished by the amount of decrease of activity and by the penetrative power and deviability of the rays emitted. In each case the final product is an inactive product.

Only three elements are generally regarded as "permanently" radio-active—uranium, thorium, and radium. In the case of these the activity of a given mass seems to be constant. However, the methods of measuring radio-activity are not very exact, and the time of observation has at the most amounted to only very few years. Hence the direct experimental proof of the permanency of radio-activity is not conclusive. On the other hand, there exists an indirect proof that the activity of these elements is not strictly permanent, but only appears to be permanent because of the extremely slow rate of disappearance of the activity. This proof is of a three-fold nature. Firstly, it is almost indisputably proved that of the three kinds of rays emitted by radio-active substances, the α - and β -rays at any rate are of a material nature (Rutherford and Soddy, *Phil. Mag.*, 1903, [6], v., 576). If this is so, radio-activity is an attendant phenomenon, if not the result of the dissipation (transformation or decomposition) of the matter which forms the radio-active substance. Hence, it is not to be expected that a radio-active substance would possess perfectly constant activity. Secondly, uranium, thorium, and radium produce temporarily active substances, as has been mentioned already. The formation and decomposition of uranium X (Crookes, *Proc. Roy. Soc.*, 1900, lxvi., 409; Becquerel, *Comptes Rendus*, 1900, cxxi., 137) has been critically examined by Rutherford and Soddy (*Phil. Mag.*, 1903, [6], v., 441), who showed that the activity of UX decreases fairly quickly (to half the initial value in twenty-two days). They also made the very important discovery that UX is not an accidental impurity in uranium compounds, but is continuously produced from uranium. A uranium compound which had been freed from UX will, after some weeks, yield a new quantity of this product, which is practically equal in amount to that which was first removed. This process can apparently be repeated without limit. The rate of loss of activity of the UX is proportional to the remaining activity. The reaction is, therefore, according to the law of mass action, one of the "first order." It is a so-called "mono-molecular reaction." The observed rate of reproduction of UX in uranium is the same as we should expect if the UX was formed at a constant rate (proportional to the practically constant mass of the uranium), and was decomposed at a rate which is always proportional to its own mass.

In a perfectly similar manner thorium continuously produces the temporarily active substance, ThX (Rutherford and Soddy, *Phil. Mag.*, 1902, [6], iv., 381); radium gives first the radium emanation. This emanation, which is formed constantly and spontaneously (Rutherford and Barnes, *Phil. Mag.*, 1904, [6], vii., 202), seems to possess a gaseous nature. It is almost certainly of a material nature. This assumption has been practically indisputably proved by Ramsay and Soddy's discovery of fundamental importance, viz., that the final transformation product of the radium emanation is helium (*Nature*, 1903, lxviii., 354; *Zeit. für Physikal. Chem.*, 1904, xlviii., 490).

In all cases hitherto studied quantitatively it has been found that the transformations of the temporarily radio-active substances are reactions of the "first order." Although the activity of these secondary substances is considerable in comparison with the activity of the elements by which they were caused, yet the actual masses are in all cases exceedingly small. Nevertheless, this continuous product of discrete particles must be followed by a perceptible or complete transformation of the original substance.*

Finally, it is very probable that radio-activity is not the result of external excitation. Radio-activity does not decrease under the heaviest lead plates, and Elster and Geitel (*Weid. Ann.*, 1898, lxvi., 735) found in the case of uranium that at the bottom of a shaft 850 m. deep no loss of activity could be observed. It is hardly probable that any external excitation could penetrate the earth's crust to such a great depth undiminished in intensity. If, therefore, the assumption that the source of the energy of radio-active substances is internal (Rutherford, *Phil. Mag.*, 1903, [6], v., 576) is correct, we must hence conclude, according to our usual conception of the conservation of energy, that no radio-active substances can continually produce energy in undiminished amount.

These observations all lead to the conclusion that the activity even of the so-called permanently active substances must decrease in course of time, and most probably according to the same law which expresses the behaviour of the less permanent substances. Many estimates have been made of the amount of loss of radium, thorium, and uranium. Rutherford (*Phil. Mag.*, 1903, [6], v., 590) concludes that, in the case of radium, the loss amounts to about 0.001 of the total mass, and that the amount of the loss is 1,000,000 times as great as that of thorium.

If these estimates as such are rightly regarded according to their order of magnitude, it is clear that a comparatively short geological period would be sufficient for practically complete decomposition, and hence complete disappearance of radium from the earth, if this were present in relatively large quantities. On the other hand, the present existence of radium on the earth can be explained by the assumption that it is continuously produced from a substance itself decomposing much more slowly. Radium would then have the same kind of relation to this mother-substance as ThX to thorium, or UX to uranium.

Such a theoretical problem of chemical dynamics may be treated by a general method. Let a series of irreversible changes be assumed, which occur according to the following scheme:—

Let each change occur in an amount proportional to the mass of the changing substance, i.e., each change is of the first order. Let the velocity constants of the consecutive changes be K_a, K_b, K_c , &c. If then A represents the mass of substance A, $K_a A$ is the mass of B which is produced in unit time, $K_b B$, the mass of C, &c. Let now the mass of A be taken as constant. Then B will be produced with uniform velocity, $K_a A$. The mass B will thus increase till the amount of B, which is decomposed in unit time, is equal to that which is formed.

* With reference to this communication of Heydendorfer (*Phys. Zeit.*, 1902, iv., 81) concerning the loss of weight of an hermetically sealed tube of a radium compound, is of great interest.

* *Ber. der Deutsch. Chem. Gesell.*, xxxvii., 2641.

That is the case if $K_b B = K_a A$. The maximum value for B is therefore reached when—

$$B = \frac{K_a}{K_b} A \quad \dots \quad (1).$$

From this point the mass B will remain constant, as K_a and K_b are constants, and A was assumed to be constant. After the mass B has reached this constant maximum, C will have the same kind of relation to B as B to A. If equilibrium has ensued, it follows that $C = \frac{K_b}{K_c} B$. Similarly, $D = \frac{K_c}{K_d} C$, &c. By combining these equations we get $C = \frac{K_a}{K_c} A$, and, finally,—

$$N = \frac{K_a}{K_n} A \quad \dots \quad (2).$$

These equations show that in a series of irreversible processes of the first order, in the case of equilibrium the mass of each product is constant, assuming that the mass of the original substance was constant.

These equations only hold for conditions of equilibrium; general equations are readily obtained. The rate of formation of B is $K_a A$. The rate of decomposition of B is $K_b B$. The rate of increase of B is therefore $K_a A - K_b B$. Thus—

$$\frac{dB}{dt} = K_a A - K_b B \quad \dots \quad (3);$$

where t denotes the time. The integral of equation (3) for $B=0$, if $t=0$, is—

$$B = \frac{K_a}{K_b} A (1 - e^{-K_b t}) \quad \dots \quad (4).$$

If $t = \infty$ $e^{-K_b t} = 0$ and $B = \frac{K_a}{K_b} A$, as before, in the case of equilibrium.

Instead of a change of mass we can similarly consider a change of activity. The latter is, in fact, what is measured. Rutherford and Soddy (*Phil. Mag.*, 1902, [6], iv., 381) have shown that the amount of increase of activity caused by the formation of ThX in a thorium preparation, which had been freed from the former product, is expressed by the equation—

$$J_t = J_0 (1 - e^{-\lambda t}),$$

where J_t denotes the activity at time t and J_0 the activity when the maximum value of ThX has been reached. λ is a characteristic constant for this reaction. This equation differs from Equation (4) in that it expresses the maximum value of the variable by means of the experimentally determined value J_0 . Equation (4) is thus more general, in that it gives the magnitude of this maximum value in terms of two velocity constants, and in that of the mass (activity) of the mother-substance. The equation of Rutherford and Soddy also expresses the changes which occur with the formation of UX from uranium (*Phil. Mag.*, 1903, [6], v., 444), and that of the radium emanation from radium (*Phil. Mag.*, 1904, [6], vii., 202).

Equation 4 enables us to calculate the time which the product needs to reach a given fraction of its maximum value. For 99 per cent of the maximum it gives—

$$e^{-Kt} = 0.01,$$

and—

$$t = \frac{2 \times 2.3}{K} = \frac{4.6}{K} \quad \dots \quad (5).$$

For 99.9 per cent of the maximum it gives—

$$e^{-Kt} = 0.001,$$

and—

$$t = \frac{3 \times 2.3}{K} = \frac{6.9}{K}.$$

The time which any product requires to reach a practical maximum is thus inversely proportional to the velocity of

its decomposition. It should be found that a limiting value is practically reached in all cases in which the velocity of the decomposition of the product is very great in comparison with that of the mother-substance, as in all such cases the above mentioned condition, that the mass of the original substance must be constant, is practically fulfilled. If, moreover, in any series of products the velocity of decomposition of a certain product, N, is very small in comparison with that of a preceding product, we can calculate the time to reach the maximum of the product N, just as if this were a direct result, as the conditions of equilibrium of the intermediate products are reached in relatively negligible times.

The Loss and Origin of Radium.

These considerations can now be applied to the case of radium. It has been shown that radium is probably decomposed at the rate of about one-tenth per cent per year. If this is correct, $K = 0.001$, if the unit of time is one year. By substituting this value in the equation $t = \frac{4.6}{K}$ we get $t \approx 4600$ years. According to this, the

amount of radium would have reached its maximum in all ores which are more than 5000 years old. From Equation

$$(1) Ra = \frac{K_1}{K} A, \text{ where } K_1 \text{ is the velocity constant of}$$

the decrease of the activity of the substance A whose decomposition either directly ($A \rightarrow Ra$) gives rise to radium, or indirectly as shown thus—

As has been previously mentioned, this condition will only actually exist if K_1 is very great in comparison with K . In this case A may be regarded as practically constant.

Now it is probable that most ores and minerals are much more than 5000 years old. According to the theory here propounded it would therefore be found that a certain relation exists between the amount of radium in an ore and that of the substance whose decomposition gave rise to the radium. The fact that radium occurs in many ores which also contain uranium seems to point to a genetic relation between the two elements. Moreover, uranium is also a radio-active substance which very probably decomposes, though, perhaps, extremely slowly in comparison with radium. If radium is actually a decomposition product of uranium it would be found that all uranium minerals contain radium in direct proportion to the uranium in them.

Moreover, all the intermediate products, such as UX or the subsequent products like the radium emanation, emanation X, &c., would also be present in amounts which are directly proportional to the percentage of uranium. Hence, it would be found that the total radio-activity of every natural uranium ore is directly proportional to the uranium it contains.

The fact that some uranium ores are considerably more radio-active than corresponds to the uranium in them led, as is well known, to the discovery of radium (P. and S. Curie and G. Bémont, *Comptes Rendus*, 1898, cxxvii., 1215). It was, however, an open question whether all ores would show an excess of activity.

In order to prove this hypothesis, a number of uranium ores from different localities were examined. Their radio-activity was measured by the electrical method, and their percentage of radium was determined. The results were in perfect agreement with the hypothesis. It was found that the activity of all uranium ores were free from appreciable amounts of thorium was directly proportional to the uranium they contained. The radio-activity of a given mass of any uranium ore divided by the percentage of uranium in the ore is constant. This constant may be called the coefficient of activity.

It has also been found that the radio-activity of uranium compounds prepared chemically is directly proportional to the amount of uranium they contain.

For such pure uranium compounds there exists also a

constant coefficient of activity. However, the magnitude of the coefficient of activity of all ores is more than five times as great as that of the pure salts. This excess in the activity of the ores is to be ascribed to the presence of radium in conjunction with the intermediate and decomposition products. The result is exactly that which we should expect if the above theory of the origin of radium is correct.

The Determination of Radio-activity.

For the determination of the radio-activity an aluminium leaf electroscope was used of the type which Hammer has described (*Trans. Am. Electrochem. Soc.*, 1902, iii., 316). It was charged by means of a battery. The earth connected metal case of the electroscope was connected with the positive pole of the battery. The plate connected with the aluminium leaf was charged by connecting with the negative pole. The position of the leaf was observed by means of a micrometer microscope whose scale had eighty divisions. The microscope was so adjusted that one end of the scale denoted a charge of about 115 volts and the other end 405 volts. For the measurements the electroscope was charged to about 240 volts. This threw the image of the little leaf off the scale. The time of the movement of the image over the eighty divisions of the scale during discharge was measured with a stop-watch which showed fifths of a second. The time of discharge through the eighty scale divisions thus amounted to about an hour if no radio-active substance was present. With 0.5 gm. of the purest ore the discharge took about fifteen seconds.

In order to determine the radio-activity of a specimen, 0.5 gm. of the finely powdered substance was distributed as evenly as possible over the bottom of a shallow round metal dish, which had a diameter of 7 c.m. The dish was placed with its contents underneath the square copper plate (5 sq. c.m.), which was connected with the aluminium leaf. The dish rested on a conducting support which was electrically connected with the earthed electroscope case. The amount of discharge depended on the distance of the copper plate from the dish (*Rutherford, Phil. Mag.*, 1899, [5], xlvii., 120). Table I. gives the times of discharge at different distances. The active substance was in each case 0.5 gm. of gummite.

TABLE I.

Distance in c.m.	Time in one-fifth second.	Mean.
8.0	97, 95, 98	97
5.9	83, 80, 83, 83	82
3.9	79, 80, 77, 78, 78	78
3.3	77, 78, 77	77
2.0	88, 87, 89	88
1.3	111, 108, 110	110

The greatest velocity of discharge was found at a distance of 3-4 c.m. In all subsequent measurements the distance amounted to 3.5 c.m. It may be seen from Table I. that the different determinations which were carried out under the same conditions did not differ from the mean by more than 2 per cent.

This represents about the degree of accuracy of the instruments employed. The times of discharge of feebly radio-active substances must be corrected on account of the spontaneous discharge of the empty electroscope. If t is the observed time of discharge for any substance and a the time if no active substance is present, the actual time of discharge θ , due to the active substance, is given by the equation—

$$\frac{t}{\theta} = \frac{1}{a} + \frac{\theta}{a - t}; \text{ whence } \theta = \frac{a \times t}{a - t}.$$

The value of a remains almost constant from day to day. Its mean value amounts to fifty-six minutes or 16,800 fifths of a second. The activity of a specimen is inversely proportional to the time of discharge θ . If the amount of uranium present is P , the coefficient of activity K is given by the equation—

$$K = \frac{1}{P \times \theta} \dots \dots \dots (6).$$

(To be continued).

ON THE CHANGES INDUCED IN THE PROPERTIES OF ELEMENTS BY VIEWING THEM UNDER OTHER EXTERNAL CONDITIONS THAN THOSE COMMON IN THE LABORATORY.

By GEOFFREY MARTIN, B.Sc. (Lond.).

THE human mind has an innate tendency to regard every quality and every quantity as discontinuous and unalterable.

For instance, our whole conception of number depends upon this mental peculiarity.

The vast mathematical fabric which has been erected upon the theory of equations ultimately depends upon the possibility of finding certain constants which will reduce certain algebraical expressions to zero—the so-called roots of the equation.

Another great branch of analysis, the invariant theory, depends upon the possibility of making these same mathematical expressions assume, not zero, but a constant value, in whatever way the variables are changed.

In science this tendency shows itself in a thousand ways. For example, we are always unconsciously endeavouring to find some rigid distinction between men and animals, animals and plants, and even between different races of men—distinctions which invariably break down as our knowledge increases.

In chemistry this human weakness is very marked. Chemists are ever, and vainly, attempting to attribute fixed and permanent characteristic constants to the different bodies which come under their hands.

For example, the boiling-points and melting-points of compounds were once assigned the proud position of invariable constants. Later, it was found that these are in reality not constant, but depend upon the external pressures to which the bodies are subjected. The colour of a compound was until lately thought to be an invariable characteristic.

Now, we know it alters with the temperature, becoming, as a rule, more intense with increase of temperature, and fading into whiteness at very low temperatures.

The metallic or non-metallic condition of an element is at the present time firmly believed by chemists to be a fixed and permanent characteristic, uninfluenced either by temperature, pressure, electric strain, or any other conceivable influence which can be brought to bear upon the element.

So that, because oxygen happens to be a non-metal, and sodium a metal, under those particular temperatures and pressures under which the chemist lives, is for him a sufficient reason for believing that oxygen will continue to remain a non-metal, and sodium will continue to remain a metal under every other conceivable physical conditions to which these two elements can be subjected—in my opinion an almost infinitely improbable contingency.

The atomic weight of an element is believed to be an absolutely unchangeable constant of an element; though why everyone should be so absolutely cocksure about this matter it is hard to say, because nobody has yet carried out very accurate weighings under temperature conditions greatly different from 18° C. In fact, no one knows anything about the matter.

We invariably find that as science advances these so-called constants are not really constants, but are variables which, under the conditions under which we live and work, are very nearly constant.

It may be gravely doubted whether any quality or any quantity associated with a body is really permanent and unalterable. When James Thomson proved that what was firmly believed to be an eternal and unchangeable constant of nature, namely, the melting-point of ice, was in reality a variable depending upon the external conditions of temperature and pressure, he caused in the scientific world a shock of surprise as great as could be caused at the

present time were some one to prove that the atomic weight of oxygen altered with the temperature and pressure.

What we intend to discuss in this article is the changeability or unchangeability of the properties of elements.

A chemist at the present time piously believes that the properties of an element, as described in the text-books, are fixed and unalterable characteristics of that element, principally, by the way, because he has never reflected on any other possibility.

Thus we read that chlorine combines vigorously with sodium, does not act on carbon, produces a very explosive compound with nitrogen, &c.; and the young student of chemistry learns painfully by heart the chemical peculiarities of O, S, N, &c., in the fond belief that they are eternal and unchangeable characteristics of those elements.

As a matter of fact, they are but the particular phase of properties which those elements exhibit under the conditions under which we live and work. Under other conditions their properties are entirely different. For example, we read that H and O gases, when heated together, combine with the evolution of heat and light to produce water. This is, however, only within a moderate temperature range. Did we happen to live at a temperature of 10,000° C., H and O would be described in the text-books as capable of existing together as a non-inflammable mixture, such as N and O gases at ordinary temperatures.

Carbon and silicon at ordinary temperatures are quite dead and inert. At a red or a white heat they wake up and become perhaps the most active substances known.

Fluorine at a very low temperature relapses into a state of chemical deadness, but at ordinary temperatures it sears the face like the vapour of white-hot steel. Nitrogen itself, so dead and inert as it appears to us, becomes a body of great chemical activity at high temperatures—inflaming, for example, in O at the temperature of the electric spark.

Chromium or iron, when made positive pole of an electric battery, assume the properties of a noble metal, like Pt or Au; made negative pole and they resume their ordinary properties (Hittorf, "Über das Verhalten des Chroms," *Zeit. für Electrochemie*, 1899, No. 1). Nitrogen, subjected to a silent electric discharge, becomes chemically active. Oxygen, under the same conditions, becomes enormously more active. Such examples can be multiplied indefinitely.

There are but two ways of regarding this matter:—Either the properties which elements happen to exhibit under ordinary conditions of temperature and pressure are unalterable, or they are not.

The evidence is, I think, overwhelmingly against the first view. The properties of an element do undoubtedly alter, and alter very considerably, according to the conditions under which it is viewed.

That the properties of an element should alter with the external conditions under which it is viewed is not very surprising when we consider that the chemical properties an element exhibits depends entirely upon the different forces with which it attracts the different kinds of atoms. And it is almost universally believed that the chemical force which an atom exerts on other atoms depends in some way or other upon the arrangement or motion of the electrons which it contains. If, then, we subject an atom to external strains, which alter the internal arrangement or motion of its electrons, then we alter at the same time the external attractive forces which the atom exerts on other atoms, and so alter the way it reacts chemically.

The temperature, electric field, probably pressure, medium, &c., are all influences which could conceivably affect the motion of the electrons within the atom, and thus affect the attractive forces of the atom.

In fact, we are probably not going too far when we suppose that the properties an element exhibits depend to a very great extent upon the external conditions to which it is subjected.

However this may be, it is certain that if we conclude that the chemical properties of an element do alter with the

external conditions, such as the temperature, then we must also conclude that there is some law, simple or complex, which regulates this change.

For the change must take place in some definite manner or other, whether that manner be complex or simple, since the element invariably returns again to its original condition when cooled to its original state.

Does there exist a simple law regulating this change? Will not a study of the behaviour of elements viewed under widely different temperatures and pressures bring to light as remarkable and undreamt of discoveries in the universe of atoms and molecules as did the observations of Kepler and Tycho-Brahe bring forth in the hands of Galileo and Newton in the universe of worlds and suns?

As a suggestion to be seriously considered in this connection, I venture to put forward the view that the properties presented by any element at ordinary temperature are only particular *phases or conditions* which can be assumed by other elements also under other and as yet unknown conditions, and that our notions of the rigidity and unchangeability of the properties of elements are completely false, and arise to a great extent because of the experimental difficulties of accurately studying the properties an element exhibits under temperature and pressure conditions very different from those which hold in the laboratory and on the earth.

Those to whom our suggestion appears most incredible are precisely those who are most ignorant of the remarkable changes which sweep over the properties of elements when viewed at high or low temperatures and in the electric field.

It should be remembered that men were once in precisely the same mental condition as regards their views of the liquid, gaseous, and solid states in which different substances find themselves when all are viewed under the same conditions of temperature and pressure, as are chemists at the present time as regards their conceptions of the different chemical states which elements find themselves in when all are viewed under the same external conditions.

Yet we all know now that the solid, liquid, and gaseous conditions of matter are only particular phases or conditions which can be assumed in succession by any substance by altering the external conditions of temperature and pressure under which it is viewed.

So also I suggest that the different chemical states which different elements find themselves in when all are viewed under ordinary conditions, are merely particular phases or conditions which any element can assume in succession by altering in an as yet unknown way the various external conditions under which elements are viewed.

It should, however, be remembered that the temperature and pressure exert a great influence on the physical state (*e.g.*, liquid, solid, or gaseous state) which a body finds itself in, because these are the influences which most affect particles of a molecular scale of magnitude.

But the change in the properties of elements depends upon the possibility of effecting matter when in a still finer state of division—the sub-atomic state of Crookes—and so would be most affected, not by the temperature or pressure, but by finer influences analogous to the temperature and pressure—"sub-temperatures" and "sub-pressures" we will call them.

In fact, just as different compounds have comparable temperatures and pressures, *i.e.*, temperatures and pressures which bring them into the same physical state, so also different elements may have comparable "sub-temperatures" and sub-pressures" which bring them into the same chemical states.

All this might appear at first sight very alarming, but it is not improbable. We are, in fact, upon the dawn of a new and grander chemistry than that which the older chemists contemplated.

Indeed, I think that it is undeniable that certain substances can be made to resemble each other more closely in properties, chemically and physically, even by the opera-

tion of such a coarse influence as the temperature. And doubtless a closer resemblance could be obtained by altering other variables simultaneously, such as the electric field, pressure, surrounding medium, &c.

Let us give some examples:

Oxygen and Sulphur.

O and S, viewed both at a common temperature, are in quite dissimilar chemical states. If, however, we view the O at ordinary temperature and the S at some 800—1000° C., the resemblance is greatly increased.

1. O and S, viewed both at ordinary temperatures, are in quite dissimilar physical states; the O is a very volatile gas, the S a solid. S viewed at, say, 1000° would become a volatile gas, just as O is at ordinary temperatures.
2. At ordinary temperatures the O molecule is O_2 and the S molecule is S_8 . If, however, we view the S at, say, 1000°, its molecules have the same composition (viz., S_2) as the O molecule at ordinary temperatures.
3. Oxygen is very much more chemically active than S, both being viewed at ordinary temperatures. At 1000° C. S is quite—nay, more—chemically active than O at ordinary temperature.
4. The majority of the compounds produced by S at ordinary temperatures have no analogies among O compounds.

For example, while H_2SO_3 and $H_2SO_3 \cdot SO_3$ are quite stable at ordinary temperatures, the corresponding O analogues are too unstable to exist. If, however, S be viewed at 1000°, these compounds would become quite as unstable as the corresponding O compounds at ordinary temperatures; SO_3 , H_2SO_4 , and H_2SO all decomposing at a red heat.

At lower temperatures, however, O would probably assume the same condition that S assumes at ordinary temperatures. Probably complex compounds of oxygen, corresponding to H_2SO_4 , SO_3 , &c., are capable of existing at lower temperatures.

Indeed, the allotropic modifications exhibited by S at ordinary temperatures would probably be paralleled by O at low temperatures. Even at ordinary temperatures two allotropic modifications (against some eight or nine known for S) of oxygen are known, viz., O_2 and O_3 . At still lower temperatures the number of these allotropic modifications will probably increase. The field of low temperature research is an unexplored world.

The Halogens.

The same appears to be the case with the halogens. Fluorine seems to be in the same chemical state at ordinary temperatures as Cl at a higher temperature. F, in fact, performs a great number of reactions at ordinary temperatures which Cl can not, but which it can when heated up.

For example, metallic Ur burns in F at the ordinary temperature, in Cl at 180°, and in Br at 210°. So that F behaves towards Ur at ordinary temperatures just as Cl at 180° and Br at a higher temperature. A similar relation appears in their behaviour with a vast number of other substances. It is, in fact, a general phenomenon.

So that by viewing simultaneously F at an ordinary temperature, Cl at about 180°, and Br at a higher temperature, we would make them all resemble each other chemically much more closely than by viewing them all simultaneously at a common temperature.

Notice that here again (as with O and S) those conditions which seem to render substances chemically more alike also render them physically more alike. For example, Cl and Br being at 180° and 210° as perfectly gasified as is F at ordinary temperatures. Viewed all at a common temperature, say, 0° C., this is not the case; F being a volatile gas, Cl an easily condensable vapour, and Br a liquid. It seems as if the same factors which determine

the chemical similarity of bodies also determine their physical similarity.

Oxygen and the Halogens.

Viewed all at a common temperature, hydride of oxygen, viz., H_2O , differs very widely in properties from the hydrides of chlorine, bromine, and fluorine, HCl, HBr, and HF. And presumably for the same reason that oxygen differs widely from chlorine, bromine, and fluorine when viewed at the same temperature.

If, however, we view the water at a high temperature and the haloid acids at ordinary temperatures, or the water at ordinary temperatures and the haloid acids at low temperatures, the resemblance between them is greatly increased, and presumably also the resemblance between O and the halogen under these conditions is greatly increased.

For example, viewed all at ordinary temperatures, we find that, though metals dissolve in HCl or HBr, evolving H and forming salts, they do not thus, as a rule, dissolve in water.

If, however, we view the acids at ordinary temperatures and the water at, say, 200—300°, we find both water and acids behave towards metals in the same way. In fact, water at 200—300° reacts with metals, evolving H and forming oxides in precisely the same way that HCl and HBr react with metals at ordinary temperatures, evolving H and forming chlorides and bromides.

Thus, although water at ordinary temperatures is a neutral substance, not reddening litmus, it seems (like HCl or HBr at ordinary temperatures) to become acid at a high temperature. For example, at 400° H_2O decomposes KCl, evolving HCl, just as H_2SO_4 decomposes it at ordinary temperatures.

Conversely, at low temperatures, HCl and HBr seem to react in the same way as H_2O at ordinary temperatures, becoming, like water, colourless liquids, incapable of reddening litmus, dissolving metals, or hydrolysing fats.

Notice that here again those conditions which bring water into a similar chemical condition as HCl or HBr also bring it at the same time into the same physical condition. For example, H_2O , viewed at ordinary temperatures, is a liquid, while HCl and HBr are gases. But water viewed at 300° is, like HCl and HBr at ordinary temperatures, a gas. Conversely, water at ordinary temperatures and the acids at low temperatures are all liquids. Now, these observations apply not only to the hydrides of O, Cl, and Br, but in general to their other binary compounds also; e.g., the metallic oxides are, as a class, more stable and less fusible and volatile than the corresponding chlorides and bromides, viewed all at the same temperatures.

If, however, we view the metallic oxides at a higher temperature than the corresponding chlorides and bromides, we tend more to equalise both their stability and their fusibility and volatility. We are, in fact, dealing with a general phenomenon common to the compound of O and H.

Upon what do the chemical properties of elements depend? Solely upon their chemical affinities. And their chemical affinities alter in relative strength and intensity as the temperature changes (and probably also with the pressure, electric field, &c.).

If, therefore, we can arrange to view two different and dissimilar elements, A and B, under two different sets of external conditions, so adjusted as to cause the affinities which A exerts to be equal or proportional to those which B exerts, we would solve the problem of making A and B chemically similar.

Whether this can actually be done or not is at present unknown. The facts we have quoted, however, are suggestive. In this connection let me mention still another possibility. If we can take advantage of the changes in the attractive force of elements caused by altering the external conditions under which they are viewed, and arrange to view simultaneously all the different elements of the Periodic System, each under a different set of

external conditions, each separate set of conditions being so adjusted as to make each of the elements thus contemplated attract the same radicles with the same (or with proportional) forces, and thus to make all the elements simultaneously chemically similar, then we would arrive at a means of unifying and simplifying the Periodic System in a way that has hitherto not been dreamt of. Chemists, here again, piously believe in the permanency and unchangeability of their Periodic Law. That it holds approximately under ordinary conditions of temperature and pressure is to them (if they have even considered the matter) a sufficient reason to make them believe that it will hold under *all* other conditions of temperature and pressure. This may be so; but in my opinion it is almost infinitely improbable.

The Periodic System, as it appears to us, is only a particular case of a general relationship which exists between the atomic weights and properties of elements. For it is the particular relation which appears between these quantities when all the elements are viewed at one particular common temperature and pressure, the particular common temperature and pressure being that under which we live, namely, about 18° C. and about 760 m.m. pressure.

But it is by no means necessary (apart from the question of the chemist's personal convenience) to view all the elements under the same conditions of temperature and pressure. If a simple relation appears when this is done then some relation will probably hold under whatever way the temperature and pressure are altered.

It is quite as probable as not that a very much more simple law would appear by viewing in the way we have suggested each particular element under a particular temperature and pressure, a definite law being supposed to regulate the temperatures and pressures under which the various elements are viewed.

For example, it is conceivable that we might make all the elements chemically similar, and thus get rid of the groups and series of the system. Or we might arrange the conditions so as to make a continual and progressive alteration of properties of the elements with increase of atomic weight, and thus again get rid of the Periodic nature of the relationship altogether.

However, this may be, it is certainly desirable that the Periodic Law should be viewed not only under atmospheric conditions, but also under a series of other temperature and pressure conditions and the law of variation found.

Indeed, as regards the various elements we are in a condition altogether analogous to that which the older chemists were in towards the various gases. For just as Boyle's law, $PV = \text{constant}$, is the law connecting the pressure and volume of gases, viewed at a constant temperature, so also the Periodic Law is the law connecting the atomic weights and properties of elements all viewed at a constant temperature. And just as Boyle's law is no longer true when the temperature is made to vary, but is a particular case of a wider law expressed by—

$$PV = RT,$$

so also the Periodic Law probably does not hold true when the temperature is made to vary, but is a particular case of a wider law, and probably a very simple law.

I have spent nearly two years studying the available data for comparing the elements and their compounds as they appear at high temperatures, with a view to tracing such a law. I have, however, failed to trace such a law, but strongly suspect that the heavy elements, such as Pb or Tl of a group of the Periodic System, are pictures of the chemical conditions which the lighter elements assume if viewed at a high temperature. So that at very high temperatures N and P would enter into a chemical condition, such as is presented by the heavier elements, Sb and Bi, of the same group, viewed at ordinary conditions, and that if viewed at still higher temperatures would enter into a radio-active condition, such as radium presents at ordinary temperatures (CHEMICAL NEWS, 1901, lxxxiii., 130; 1902,

lxxxv., 205—310). So that if we view the different elements of Mendeleeff's Periodic System, the lightest series at the highest temperatures, and the heaviest series at the lowest temperatures, we might in this way reduce to uniformity the Periodic System. According to the modern electron theory, increase of temperature should increase the atomic weight, because it increases the motion of the electrons which compose the atom.

Data is, however, wanting, and will be wanting for fifty years to come.

All these are dreams, speculations, what you will. Our knowledge of chemistry is yet in an embryo state, and we cannot say what is possible and what is not. Yet the reader should not scoff these dreams as incredible. They were suggested by a very intimate study of the facts now known, facts which the reader has probably never considered.

Let him remember that the dream of to-day is the living reality of to-morrow, and that coming events cast their shadows before them. The human mind is ever calling out for the new and unknown. The great labours of the atomic weight determinations were inspired and directed by the living underlying belief that some great and simple law would become apparent when we knew these constants more exactly. No man, for example, would have spent his life, as Stas did, in determining the atomic weights was he not borne up and sustained by the great theoretic interests underlying his observations.

University of Kiel.

ON THE PENTAVALENT NITROGEN ATOM.*

By Professor OSSIAN ASCHAN.

THE author has previously expressed the view (*Zeit. Phys. Chem.*, 1903, 46, 293), which is in accordance with that of van't Hoff ("Die Lagerung der Atome in Raume," 1894, 2te. Aufl., 136), that the valency directions of the pentavalent nitrogen atom are arranged as in the appended figure.

By the addition of trimethylene bromide,—

to ethylenedipiperide, $\text{C}_8\text{H}_{10} \cdot \text{N} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NC}_4\text{H}_9$, and of ethylene bromide to trimethylenedipiperide, $\text{C}_8\text{H}_{10} \cdot \text{N} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{NC}_4\text{H}_9$, the author has obtained two stereomeric compounds having the constitution,—

which he was unable to resolve into optically active components by the aid of Pope's method with *d*-camphorsulphonic acid. Both compounds would therefore seem to possess symmetrical configurations, and this is only possible if the above conception of the arrangement of the valency directions of the pentavalent nitrogen atom is correct.

Since the attempts at resolution were carried out in aqueous solution, and as possibly the *d*-camphorsulphonic acid is not capable of effecting an easy separation of the stereoisomerides, the two ethylenetrimethylenedipiperide

* Read before the British Association (Section B), Cambridge Meeting, 1904.

dibromides were caused to react with silver *d*-bromocamphorsulphonate in absolute methyl alcoholic solution. Both gave highly crystalline ethylenedimethylene-dipiperidide *d*-bromocamphorsulphonates, which by crystallisation were separated into four and three fractions respectively, the fractions being then converted into the difficultly soluble iodide by precipitation with potassium iodide. The samples of iodide from the first and last fractions were then immediately examined polarimetrically, but were found to be optically inactive.

The author finds in these results a confirmation of his previously expressed views on the configuration of ammonium compounds, and notes also that this view possesses the greatest probability on grounds of a mechanico-chemical nature.

THE STEREOCHEMISTRY OF NITROGEN.*

By H. O. JONES, M.A., D.Sc.

THIS report, which was intended to form the basis for a discussion, contains a summary of the work which has been done on all branches of the subject, but deals more especially with the isomerism observed in quinquivalent nitrogen compounds.

The following is a brief *resumé* of the principal subjects discussed:—

1. Tervalent Nitrogen Compounds.

The Problem of Optical Activity.—It might be expected from purely dynamical considerations that the most stable configuration for three atoms or groups attached to one atom (nitrogen) would be that in which all three groups were situated in the same plane with that atom. A displacement of one of the groups out of this plane might occur under certain circumstances, as, for instance, when strain is introduced by the formation of a double bond.

These conclusions are supported by experiment. The numerous attempts to obtain optically active tervalent nitrogen compounds, terminating with the experiments of Mr. J. P. Millington and the writer on compounds in which the valency of the nitrogen was not altered (from three to five) during the process, which have been unsuccessful; and the experiments of Messrs. Kipping and Salway, in which it was proved that the substituted acid amides produced by the interaction of an acid chloride containing an asymmetric carbon atom with various amines were homogeneous, and that therefore the nitrogen does not form a centre of asymmetry, afford fairly conclusive evidence of the plane configuration of compounds of the type *N.a.b.c.*

The existence of inactive isomerides is doubtful except in the case of tropine and tropylamine.

The well known isomerism of compounds of the type $\begin{smallmatrix} a \\ b \end{smallmatrix} > C = N - c$, illustrated by the oximes and hydrazones, is then briefly discussed. The very large number of experimental facts which have been collected since the discovery of the first isomeric benzil dioxime by Goldschmidt and V. Meyer in 1883 are accounted for in a satisfactory and consistent manner by the hypothesis of Hantzsch and Werner only. This hypothesis assumes that, in compounds in which a nitrogen atom is attached by a double union to another atom, there are two positions of equilibrium for the group attached to the third valency. The two isomerides being represented thus—

The consequences of the hypotheses have been fully verified for a large number of oximes and dioximes for hydrazones, aniles, and diazo compounds, but not for azo-compounds.

* Read before the British Association (Section B), Cambridge Meeting, 1904.

2. Quinquivalent Nitrogen Compounds.

Although a very large amount of work has been done on substituted ammonium compounds, the phenomena exhibited by them are so complicated, and in many respects so unlike those exhibited by asymmetric carbon compounds, that it is clear much more must be done before any definite conclusion can be arrived at.

i. *Compounds of the Type $N a_3 b X$* , where *a* and *b* represent mono-valent atoms or groups and *X* represents the acidic radical.

Isomerides of these compounds only exist in certain special cases in which *b* and *X* both contain an asymmetric carbon atom, observed by Professor Kipping and his collaborators. It has been conclusively proved that both *d*- and *l*-hydriindamine on combining with certain active acids, *d*-brom-camphorsulphonic acid, for example, give rise to two salts called *al* and *βl* and *al* and *βl* respectively; these salts combine to produce racemic compounds, which are very difficult to resolve. This isomerism is of theoretical importance, but is not of general occurrence, and it is evident that the discovery of the conditions determining the existence of these isomerides would throw much light on the phenomena observed in other quinquivalent compounds.

ii. *Compounds of the Type $N a_2 b c X$* have not been shown to exist in isomeric forms, though many attempts have been made by the writer and others to prepare them; but isomerism of a somewhat different kind has been observed by Aschan in the ethylene-trimethylene-dipiperidinium dibromides and diiodides.

iii. *Compounds of the Type $N a.b.c.d.X$* .—A very large number of compounds of this type have been prepared in all the possible ways, and though in some cases differences exist, these disappear on solution; no definite isomerism has been observed, except in one isolated instance, the *a*- and *β*-phenyl-benzyl-allyl-methyl-ammonium salts prepared by Wedekind. The very similar *p*-tolyl-benzyl-allyl-methyl, phenyl-benzyl-ethyl-methyl, and phenyl-allyl-ethyl-methyl ammonium compounds do not exist in definite isomerides.

Wedekind finds that isomerism apparently exists in some di-tertra-hydroquinolinium derivatives.

iv. *Optical Activity of Quinquivalent Nitrogen Compounds.*—Compounds of the types $N a_3 b X$ and $N a_2 b c X$ do not appear to be capable of giving rise to optical activity, while those of the type $N a b c d X$ can be resolved into optical antimers. The first compounds obtained in the active form were the *a*-phenyl-benzyl-allyl-methyl-ammonium compounds prepared by Messrs. Pope and Peachey. The basic ion was found to have a molecular rotatory power of about 166°. The writer succeeded in resolving phenyl-benzyl-ethyl-methyl-ammonium salts, and found the basic ion to have a rotatory power of about 19°; a series of compounds are being resolved by Miss M. B. Thomas and the writer with a view of investigating the remarkable effect of substitution on the rotatory power.

The analogy between asymmetric nitrogen and carbon atoms has been further extended by the writer by showing that when a tertiary amine containing an asymmetric carbon atom (methyl-*l*-amyl aniline) unites with an alkyl iodide (allyl and benzyl iodide) unequal quantities of the two possible compounds are produced.

v. *The Configuration of Quinquivalent Nitrogen Compounds.*—The existence of optical activity in substituted ammonium compounds shows that the compound is atomic, and has a spatial configuration which is devoid of a plane of symmetry.

The three principal configurations proposed, namely, the "cubic" of van't Hoff, the "double tetrahedral" of Willgerodt, and the "pyramidal" of Bischoff, are discussed in relation to the facts stated above. The tetrahedral configuration will not explain the existence of the isomeric hydriindamine salts, while both the cubic and tetrahedral configurations require, in general, a larger number of isomerides than the pyramidal. The pyramidal configuration is shown to be capable of accounting for all the known

facts, if it be assumed that during the addition of dX or HX to an amine, the acidic radical X takes up a position at the base of the pyramid, and is then capable of changing positions with the radical at the apex.

The existence of isomerism in compounds of the type $NabcdX$ in one case and its non-existence in all the other cases examined is difficult to explain, but possibly this depends on some peculiar relation between certain alkyl radicals, since hydrindamine salts with active acids behave similarly; that is, show sometimes isomerism and sometimes do not.

The existence and optical inactivity of the isomeric dipiperidinium compounds observed by Aschan is readily explained in a simple manner by the above view.

Reference must be made to the original for references and for the detailed discussion.

LUTES.*

By SAMUEL S. SADTLER.

(Concluded from p. 183).

VI. Resin, Shellac, and Wax.

A STRONG cement used as a stone cement is—

1. Resin	8 parts
Wax	1 part
Turpentine	1 "

It has little or no body, and is used in thin layers.

For nitric and hydrochloric acid vapours:—

2. Resin	1 part
Sulphur	1 "
Fire-clay	2 parts

Sulphur gives great hardness and permanency to resin lutes, but this composition is somewhat brittle.

Good waterproof lutes of this class are—

	Parts.
3. Resin	1
Wax	1
Powdered stone	2
4. Shellac	5
Wax	1
Turpentine	1
Chalk, &c.	8 to 10

For a soft air-tight paste for ground-glass surfaces:—

5. Wax	1
Vaseline	1

6. A strong cement, without body, for metals (other than copper or alloys of same), porcelain, and glass is made by letting 1 part of finely-powdered shellac stand with 10 parts of ammonia water until solution is effected.

VII. Rubber.

Because of its toughness, elasticity, and resistance to alterative influences, rubber is a very useful constituent in lutes, but its price makes its use very limited.

Leather cement:—

	Parts.
1. Asphalt	1
Resin	1
Gutta-percha	4
Carbon disulphide	20

To stand acid vapours:—

2. Rubber	1
Linseed oil	2
Fire-clay	3

Cement for mending rubber:—

3. Rubber, crude (sliced) ..	1
Resin	$\frac{1}{2}$
.. .. .	8

4. *Plain Rubber Cement.*—Cut the crude rubber in small pieces and then add the solvent. Carbon disulphide is the best, benzol good and much cheaper, but gasoline is probably most extensively used because of its cheapness.

5. To make corks and wood impervious to steam and water, soak them in a rubber solution as above; if it is desired to protect them from oil vapours, use glue composition (see Section IX.).

VIII. Linseed Oil.

This is one of the most generally useful substances we have for luting purposes, if absorbed by a porous substance that is inert.

Formulae:—1. China-clay } Of general utility for aqueous
Linseed oil } vapours.

2. Lime
Linseed oil } Forming the well known putty.

3. Red or white lead and linseed oil.

These mixtures become very strong when set, and are best diluted with powdered glass, clay, or graphite. There are almost an endless number of lutes using metallic oxides and linseed oil. A very good one, not getting as hard as those containing lead, is—

4. Oxide of iron and linseed oil.

IX. Casein, Albumen, and Glue.

These, if properly made, become very tough and tenacious; they stand moderate heat and oil vapours, but not acid vapours.

1. Finely-powdered casein	12 parts
Slaked lime (fresh)	50 "
Fine sand	50 "
Water to thick mush.	

A very strong cement for ground unions, stands moderate heat, as follows:—

2. Casein in very fine powder ..	1 part
Rubbed up with silicate of soda	3 parts

A strong lute for general purposes, which must be used promptly when made:—

3. White of egg made into a paste with slaked lime.

A composition for soaking corks, wood, packing, &c., to render them impervious to oil vapours, is:—

	Parts.
Gelatin or good glue	2
Glycerin	$\frac{1}{2}$ to 1
Water	6
Oil of wintergreen, &c., to keep from spoiling.	

X. Silicate and Oxychloride Cements.

For oil vapours, standing the highest heat:—

1. A stiff paste of silicate of soda and asbestos.

Gaskets for superheated steam, retorts, furnaces, &c.:—

2. Silicate of soda and powdered glass; dry the mixture and heat.

Not as strong, however, as the following:—

3. Silicate of soda	50 parts
Asbestos	15 "
Slaked lime	10 "

Metal cement:—

4. Silicate of soda	1 part
Oxides of metal, such as zinc oxide, litharge, iron oxide (singly or mixed)	
	1 "

* from the *Journal of the Franklin Institute*, clviii., No. 5.

Very hard and extra strong compositions :—

5. Zinc oxide 2 parts
Zinc chloride 1 part
Water to make a paste.
6. Magnesium oxide 2 parts
Magnesium chloride 1 part
Water to make a paste.

XI. Flour and Starch Compositions.

1. The well-known flax-seed poultice sets very tough, but does not stand water or condensed steam.
2. Flour and molasses, made by making a stiff composition of the two. This is an excellent lute to have at hand at all times for emergency use, &c.
3. Stiff paste of flour and strong zinc chloride solution forms a more impervious lute, and is more permanent as a cement. This is good for most purposes, at ordinary temperature, where it would not be in contact with nitric acid vapours or condensing steam.
4. A mixture of dextrin and fine sand makes a good composition, mainly used as core compound.

XII. Miscellaneous.

1. Litharge.
Glycerin.

Mixed to form a stiff paste, sets and becomes very hard and strong, and is very useful for inserting glass tubes, &c., in iron or brass.

For a high heat :—

2. Alumina 1 part
Sand 4 parts
Slaked lime 1 part
Borax ½ "

Water sufficient.

Of course, there are an almost infinite number of lutes or cements, but, classified as these are, they represent the largest number of them. The formulae that are not original, or were kindly given by friends, have been seen in the literature, one here and one there, and laid aside for a year or more, so I can hardly give the credit for them that I would like to.

A class of mixtures that can only be classified according to their intended use are core compounds.

1. Dextrin, about 1 part
Sand, about 10 parts
With enough water to form a paste.
2. Powdered anthracite coal, with enough molasses to form a stiff paste.
3. Resin, partly saponified by soda-lye 1 part
Flour 2 parts
Sand (with sufficient water) 4 "

(These proportions are approximate, and the amount of sand can be increased for some purposes).

4. Glue, powdered 1 part
Flour 4 parts
Sand (with sufficient water) 6 "

For some purposes, the exact uses of which I am not familiar, the following mixture is used. It does not seem to be a gasket or a core compound :—

5. Oats (or wheat) ground 25 parts
Glue, powdered 6 "

Sal ammoniac 1 part

I would say, in conclusion, that in any works or laboratory it is very good to have some such compositions made up ready to use without delay when wanted. Just which one, depends on the nature of the manufacturing or other work done.

I hope that the material contained in this paper may prove of benefit to some of my readers.

THE USE OF FERROUS SULPHATE IN THE ESTIMATION OF CHLORATES AND BROMATES.*

By I. K. PHELPS.

In a recent article, a method for the titrimetric estimation of nitric acid or nitrates was described (*Am. Journ. Sci.*, 1902, xiv., 440). It consisted, briefly, in the measurement of the amount of ferrous salt oxidised in the reduction of the nitric acid to nitric oxide by an excess of ferrous sulphate in the presence of hydrochloric acid. The value of ferrous sulphate as a reducing agent in analytical processes has long been recognised on account of its ready availability, the high degree of precision with which it may be determined, and the extreme slowness with which it is oxidised by atmospheric oxygen. This last fact was clearly shown by Peters and Moody (*Am. Journ. Sci.*, 1901, xii., 369) for solutions which had been allowed to stand until all active oxygen, dissolved in the water, or otherwise present, had produced its effect. The author was surprised to find that, in boiling such solutions in the open air and cooling with stirring in running water, no distinctly perceptible change could be noted, although the oxidation from day to day was plainly evident.

Carot (*Comptes Rendus*, cxviii., 449) has suggested the use of ferrous sulphate for determining the oxygen in hypochlorites and chlorates in admixture with chlorides, but gives no evidence to show the degree of accuracy of the process. Table I. records experiments made with the purest potassium chlorate of commerce to test this point. The dry salt was weighed out, treated with an excess of standardised ferrous sulphate solution (approximately $n/5$), and with 15 c.m.³ of sulphuric acid (1:4). This mixture was brought to the boiling-point in a trapped flask, cooled to room temperature by immersion in running water, diluted to a volume of 600 c.m.³, and, after the addition of 1–2 grms. of manganous chloride, titrated to colour with standard potassium permanganate solution.

Table II. records similar experiments made upon a sample of thrice crystallised potassium bromate which was prepared by acting on potassium hydroxide with bromine evolved from pure potassium bromide by sulphuric acid and manganese dioxide. The experiments were performed like those with the chlorate, described above, except that the

* Contributions from the Kent Chemical Laboratory of Yale University. From the *American Journal of Science*, [4], viii., No. 99.

excess of ferrous salt used in the reduction was determined by decinormal iodine in alkaline solution instead of by permanganate in acid solution. The solution was cooled after boiling, was nearly neutralised with a concentrated solution of sodium carbonate, and was then treated with 2-3 grms. of Rochelle salt in solution and an excess of decinormal iodine solution. The mixture was made alkaline with an excess of potassium bicarbonate solution, starch paste added, the starch blue bleached with decinormal arsenious acid, and, finally, the excess of this last titrated to colour with iodine.

An inspection of the results shows that the processes may be justly considered as accurate for analytical purposes—especially so when one considers that they measure only the oxygen in the salt analysed, which is 39 per cent for potassium chlorate and 28 per cent for potassium bromate.

A NEW SEPARATION OF THORIUM FROM CERIUM, LANTHANUM, AND DIDYMIUM BY METANITROBENZOIC ACID.*

By ARTHUR C. NEISH.

THE work herein described was undertaken with the object of finding a shorter and more satisfactory method for the determination of thorium in monazite sands.

The requirements of such a method are—First, an accurate separation of thorium from cerium, lanthanum, and didymium; second, rapidity and ease of manipulation; third, an inexpensive reagent, and one which does not involve the use of alcohol.

It is believed that the method described meets these conditions.

As the analytical methods have been so recently reviewed by Metzger (*Journ. Am. Chem. Soc.*, 1902, xxiv., 901; *CHEMICAL NEWS*, lxxxvi., 218), and a bibliography to the entire literature of thorium recently published by Jouet (*Smithsonian Miscellaneous Collections*, No. 1374), the usual historical review of the literature pertaining to the subject is omitted.

Preparation of Pure Thorium Nitrate.

The pure thorium nitrate was made by dissolving 200 grms. of chemically pure thorium nitrate—containing a small percentage of cerium—in water in thirteen beakers, each holding about 1000 c.c. To each beaker 150 c.c. of hydrogen peroxide (Marchand's medicinal, containing about 4 per cent hydrogen dioxide) was added (10 c.c. for every 0.5 gm. thorium oxide). The solutions were heated to 85° C. and allowed to settle. The precipitates were washed by decantation, and at the end of the sixth decantation the filtrate gave no test whatever for cerium on the addition of ammonia. The precipitates were transferred to a large Büchner funnel and the washing continued, stirring the precipitate with a spatula. The precipitate was transferred to a large evaporating dish, and 250 c.c. of concentrated nitric acid added, which readily dissolved the precipitate when a little heat was applied. The solution was evaporated to dryness, taken up with water, diluted, and divided among the thirteen beakers so that each contained about a litre, and the thorium re-precipitated as before. The precipitate was dissolved in nitric acid and evaporated to dryness, and dried in the air-bath for three days at 115° C. This gave thorium nitrate of the highest purity, containing no free nitric acid.

Sixty grms. of this thorium nitrate were dissolved in 7 litres of water, well shaken, and divided among several well-stoppered bottles.

Standardising the Thorium Solution.

A very accurately standardised burette was used to measure out the thorium nitrate solution; it was connected to the bottle by glass tubing, so as to facilitate filling without any chance of change due to evaporation or contamination.

Different amounts of thorium solution were run into a number of small beakers and heated to boiling, and a boiling solution of oxalic acid (saturated in the cold) was added, a little at a time with constant stirring. After cooling, the precipitate was filtered and washed with water. If precipitated from cold solutions, the precipitate runs through the paper, but from hot solutions no trouble in filtering is encountered. The paper containing the thorium oxalate was placed in a weighed platinum crucible, gently heated with a Bunsen burner until dry and the paper charred, then the heat was increased and the oxalate changed to oxide; it was next heated by a blast-lamp for fifteen minutes, cooled, and weighed. Table I. gives the results.

50	40	0.2255	0.004510

Precipitants Tried.

Many organic precipitants were tried, mostly weak organic acids, in the hope of finding one that would give a sharp separation, and a precipitate which would filter quickly without the use of alcohol.

The results are briefly as follows:—

Gallic acid precipitates thorium quantitatively from a hot alcoholic solution as a flocculent slimy precipitate. Salts of cerium, lanthanum, and didymium are not precipitated.

Tannic acid precipitates thorium quantitatively, but cerium, lanthanum, and didymium are not precipitated.

Citric acid precipitates all from an acetone solution.

Salicylic acid precipitates thorium. The precipitate is soluble in excess of the reagent.

Oleic acid in a strong alcoholic solution precipitates thorium and cerium. The cerium precipitate is soluble in excess, the thorium insoluble.

Linoleic acid precipitates all, if insufficient alcohol is present, but with sufficient alcohol the cerium, lanthanum, and didymium readily dissolve; the thorium is apparently insoluble.

Paratoluic acid gave a precipitate of thorium, but none with cerium, lanthanum, and didymium.

Oxysiphthalic acid gave a white curdy precipitate of thorium in an aqueous solution, almost quantitatively; the other three earths gave no precipitate.

Benzoic acid precipitated thorium quantitatively from aqueous solution; the cerium, lanthanum, and didymium were not precipitated. This method gives trouble, on account of the very slight solubility of benzoic acid in water.

The three nitrobenzoic acids gave white precipitates with a neutral solution of thorium nitrate, while cerium, lanthanum, and didymium gave no precipitate. The meta acid, which is the most soluble in water, precipitated the thorium quantitatively. This acid is the principal product of the nitration of benzoic acid, the yield being about 75 per cent; but as the ortho- and para-acids, as well as benzoic acid, act similarly, it is not necessary to use pure metanitrobenzoic acid, and the reagent is one readily obtained.

Potassium iodate precipitates all four as heavy white precipitates.

* Read at the meeting of the New York Section of the American Chemical Society, May 6, 1904. From the *Journal of the American Chemical Society*, xxvi., No. 7.

Ammonium vanadate precipitates thorium, lanthanum, and didymium as canary-yellow precipitates; the cerium precipitate has an orange colour.

Lead acetate in a solution acid with nitric acid produces a white precipitate with thorium, which increases when heated, but is incomplete. Cerium, lanthanum, and didymium are not precipitated.

Arsenious oxide cream precipitates all four quantitatively in a solution containing sodium acetate.

Sodium tungstate precipitates all four as white precipitates.

Quantitative Precipitation of Thorium by Metanitrobenzoic Acid.

The solution of the precipitant is made by dissolving from 3.5 to 4 grms. of the acid in a litre of hot water (about 80° C.). When all is in solution, it is allowed to stand overnight, when a slight amount will separate out as feathery crystals. The solution is filtered to free it from any crystals and foreign matter.

Thorium nitrate solution was run into a 300 c.c. beaker and a solution of the precipitant added very slowly with constant stirring; about 150 c.c. gave a liberal excess for 25 c.c. of thorium solution equivalent to 0.1128 gm. of thorium oxide. This produces a heavy white precipitate, which soon collects on standing, more rapidly on heating. The beaker was heated on the water-bath to a temperature between 60° and 80° C. for fifteen minutes. The opalescence disappears, and the bulky precipitate settles to the bottom in large flocks having much the appearance of silver chloride. The solution can either be filtered hot or allowed to cool. The precipitate is washed first by decantation and finally on the filter-paper with a 5 per cent solution of the precipitant. The precipitate and paper are not dried, for reasons given later, but placed moist in a weighed platinum crucible and carefully heated with the cover off; then, after the paper and volatile matter are driven off, heated with the full flame of a Bunsen burner until white, then covered and ignited for fifteen minutes with the blast-lamp, cooled, and the thorium oxide weighed.

Table II. shows that thorium is quantitatively precipitated from a neutral solution of the nitrate by metanitrobenzoic acid.

TABLE II.

NOTICES OF BOOKS

Chemical Technology and Analysis of Oils, Fats, and Waxes. By Dr. J. LEWKOWITSCH, M.A., F.I.C. Third Edition. London: Macmillan and Co., Limited. New York: The Macmillan Company. 1904.

THE third edition of this valuable and compendious work has been enlarged to such an extent as to alter its form completely from that of the original, so that it represents practically a new work. The physical and chemical properties and the analysis of all known oils, fats, and waxes occupy the whole of the first volume, while the second is devoted to the chemical technology of oils and fats, manufacturing processes being discussed and in some cases illustrated, and the naturally occurring substances and their properties fully described. In the present form this work is undoubtedly the most complete on the subject in the language, and evidently every possible care has been taken to bring this edition up to date, and to make it quite indispensable to the technical chemist.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 10, September 5, 1904.

A Characteristic Reaction of Hydrogen Phosphide, Arsenide, and Antimonide.—P. Lemout.—Mercuric iodide, when dissolved in water in presence of potassium iodide, constitutes a very sensitive reaction, identifying the three gases PH₃, AsH₃, and SbH₃. In each case reduction takes place, and a very characteristic crystalline precipitate is formed of a yellowish orange, clear brown, or brownish black, of the type of mercury iodophosphide, PHg₃I₃, and whose formation can be easily demonstrated by a series of experiments. The reaction may be expressed by the equation $\text{PH}_3 + 3\text{HgI}_2 = 3\text{HI} + \text{PHg}_3\text{I}_3$.

Benzopinacone and Benzopinacoline.—Amand Valeur.—The author previously investigated the action of bibasic acid ethers, and particularly methyl oxalate on phenyl-magnesium bromide, C₆H₅MgBr. By the action of ethyl oxalate on phenyl-magnesium bromide W. Dilthey and E. Last obtained a substance fusing at 181°, but which could not be analysed, and which possessed all the properties of β -benzopinacoline. However, by applying the same reaction to methyl oxalate, the author obtains, not a benzopinacoline, but the benzopinacone, (C₆H₅)₂C(OH)—C(OH)(C₆H₅)₂.

No. 11, September 12, 1904.

PRACTICAL AND THEORETICAL TUITION

In Botany, Chemistry, Pharmacology, and Therapeutics for All Medical and Science Examinations.

Special Course of Instruction in Therapeutics, Pharmacology, and Microscopy for Institute of Chemistry Exam.

To Chemical Manufacturers, Iron and Metal Merchants, and others.—Messrs.

FULLER, HORSEY, SONS, and CASSELL are instructed to **SELL by AUCTION**, at the Lea Chemical Works, Carpenters' Road, Hackney Wick, on **THURSDAY, Oct. 20**, at Eleven o'clock precisely.

CHEMICAL PLANT and MACHINERY, including about 60 tons of lead in tanks, coolers, vats, &c., enamelled iron baths, two pairs vacuum pumps, Johnson's air compressor, seven steam and other pumps, quantity lead and enamelled iron trays, pair of edge runners, three acid grinding mills, three sizers, two ranges of coke ovens, disintegrator, water softening apparatus, large quantity of tin, lead, and iron piping and cocks, aluminium trays, three w.i. water tanks up to 3000 gallons, about 30 tons c.i. floor plates, Tangies' 17-n h.p. horizontal steam engine, three smaller steam engines, two Lancashire boilers, 7 ft. and 7 ft. 6 in. diameter, 30 ft. long, two elephant b'lers, shafting and belting, steam winch, crab, 10 cwt. weighing machine, 7½ cwt. screw cutting lathe, four cranes, blocks, and chain, quantity stores and material, office furniture, and Effects.—May be viewed and catalogues had of Messrs. **KINGSFORD and DRAKE**, Solicitors, Bank Street, Ashford, Kent; and of Messrs. **FULLER, HORSEY, SONS, and CASSELL**, 11, Billiter Square, E.C.

Re Frederick Allen and Sons (Limited).—By Order of the Receiver for the Debenture Holders.

To Chocolate Manufacturers, Wholesale Confectioners, Manufacturing Chemists, Box-makers, Engineers, and others.—Messrs.

FULLER, HORSEY, SONS, and CASSELL are instructed to **SELL by AUCTION**, in Lots, on the Premises, Devon Wharf, Emmott Street, Mile End, E., on **TUESDAY and WEDNESDAY, Nov. 1 and 2**, at Eleven o'clock precisely each day.

MODERN CHOCOLATE PLANT and MACHINERY, including 14 grinding and mixing machines, five pairs French burr grinding stones, two pairs edge runners, three cocoa separating and dressing machines, two cocoa roasting machines, eight sets making and refining rolls, ten copper boiling and mixing pans, four caramel machines, five moulding tables, eleven rapping tables, twelve mould drying closets, two cream mixing machines, 15 covering tables, two furnaces, 17 runchas, four freezing chambers.

A COMPLETE REFRIGERATING PLANT, with two ammonia compressors and engines, two ammonia condensers, refrigerating and brine tanks, eight brine and other pumps, two Galloway boilers, a Green's economiser, two compound condensing beam engines, six horizontal engines, five steam pumps, shafting and gearing, driving bands, loose tools, utensils, and stock; immediately following the sale of the chocolate plant there will be sold the nearly new

BOX-MAKING PLANT and MACHINERY, at the Bell Wharf Box Works, adjoining, including twelve circular saw benches, band saw machine, seven panel, lighting, and hand-d planing machines, box perforating and printing machines, 15 Webster's box-nailing machines, three trimming machines, saw sharpener, hoop-iron punching machine, glue-heating apparatus, two horizontal steam engines, two pumps, tanks, shafting, &c.—May be viewed, and catalogues had of the Receiver, Mr. EDWARD H. FLETCHER (of Messrs. Cooper Bros. and Co.), Chartered Accountant, 14, George Street, Mansion House, E.C.; of Messrs. **BADDELEY and CO.**, Solicitors, 60, Leadenhall Street, E.C.; or of Messrs. **FULLER, HORSEY, SONS, and CASSELL**, 11, Billiter Square, E.C.

VOL. XC., No. 2343.

THE ORIGIN OF RADIUM.*

By HERBERT N. MCCOY.

(Concluded from p. 189).

The Activity of Pure Uranium Compounds.

For the determination of the relation between activity and amount of uranium present two series of experiments were performed. In the first, intimate mixtures of a specimen of pure uranium acetate were prepared with finely powdered SiO_2 in the proportions of 1 to 1, 1 to 3, and 1 to 7. The activity of portions of $\frac{1}{2}$ grm. of each mixture, and also that of the pure salt, were determined. It was found that the time of discharge depended to a certain extent on the way in which the material was distributed in the dish. The greatest activity accompanied the most uniform distribution. Successive distributions of the same specimen, each as uniform as possible, give values often differing by 3–4 per cent. For this reason two or more distributions were usually made with each specimen, and the determination of the activity repeated. In the following statements the results of determinations with the same distribution are separated by commas (,) and the different distributions by semi-colons (;). The numbers denote the time (t) for the discharge of the electroscope through 80 scale divisions in fifths of a second. The corrected time, θ , was calculated by the help of Equation (6).

Pure uranium acetate:—478, 479, 480; 478, 476, 478. Mean 478. $\theta = 492$.

One part of uranium acetate to one part SiO_2 :—968, 994, 999; 956, 964. Mean 974. $\theta = 1034$.

One part of uranium acetate to three parts SiO_2 :—1850; 1904. Mean 1877. $\theta = 2110$.

One part of uranium acetate to seven parts SiO_2 :—3450. $\theta = 4340$.

Table II. gives the collected results. The value of K is in each case multiplied by the factor 10*.

TABLE II.

Parts SiO_2 to one part uranium acetate.	θ .	P.	K.
0	492	56	3'62
1	1034	28	3'45
3	2110	14	3'38
7	4340	7	3'29
Mean			3'44

The coefficient of activity, K, is nearly constant. The activity is practically proportional to the amount of uranium present.

In the second series, the activity of portions of $\frac{1}{2}$ grm. of different pure uranium compounds was determined. The descriptions of the specimens and the results obtained are given in the following:—

1. "Uranous Oxide Black" (Kny):—252, 251; 255, 260. Mean 255. $\theta = 259$.
2. "Uranous Oxide Black" (C. A. F. Kahlbaum):—267, 272; 263, 262. Mean 266. $\theta = 270$.
3. "Uranic Acid" (Kny):—290, 292; 308, 306. Mean 299. $\theta = 303$.
4. "Uranic Nitrate" (Kahlbaum, Kny):—637, 635; 617, 614. Mean 626. $\theta = 650$.
5. "Uranic Acetate" (Kny):— $\theta = 492$.
6. "Uranic Acetate" (Kahlbaum):—524, 525; 540, 524. Mean 528. $\theta = 545$.

* *Ber. der Deutsch. Chem. Gesell.*, xxxvii., 2641.

All these salts had been several years in the laboratory. They were thus old enough to contain the maximum of UXt (Rutherford and Soddy, *Phil. Mag.*, 1903, [6], v., 441).

Table III. gives the collected results.

TABLE III.

Number.	Formula.	θ .	P.	K.
1.	U ₃ O ₈	259	85	4'55

6.	UO ₂ (C ₂ H ₃ O ₂) ₂ ·2H ₂ O	545	56	3'28
	Mean			3'86

The value of K is not perfectly constant. Two reasons can be given for this. In the first place the percentage of uranium used for the calculation of the value of K is the amount given by the usual formula. This is probably not the exact or even approximate value. Secondly, as the following pages will show, all uranium ores are more than five times as active, in comparison with the uranium they contain, as the chemically pure preparations.

Hence it follows that the process of purification more or less removes the strongly active adulterations. But as the degree of purity of the so-called pure substances differs in different cases, it is not remarkable that for this reason also the radio-activity shows some changes. This point thus requires further careful study. These results also illustrate the fact that the degree of absorption of radio-active rays by the same quantities of different substances is independent of the nature of the substance (Strutt, *Nature*, 1900, lxi., 531; see also Lenard, *Wied. Ann.*, 1895, lvi., 255).

Method of Analysis of Uranium Ores.

The determination of uranium is perhaps performed most quickly by reduction with zinc in dilute sulphuric acid and subsequent titration with potassium permanganate (Kern, *Journ. Am. Chem. Soc.*, 1901, xxiii., 685; Pulman, *Am. Journ. Sci.*, 1903, xvi., 229). The method is quick and fairly accurate. For the determination of uranium in pitchblende or gummitte, which contain iron, lead, calcium, and perhaps thorium as well as uranium, the ore is dissolved in warm dilute nitric acid and treated with a large excess of saturated solution of sodium carbonate (Patera, *Zeit. fur Anal. Chem.*, 1866, v., 228). After boiling for two minutes the precipitate, which contains all the iron, together with calcium, thorium, and the greater part of the lead, is filtered off. The filtrate, which contains all the uranium, is neutralised with sulphuric acid, and heated to drive off the carbon dioxide. The uranium is then precipitated as sodium uranate with sodium hydroxide, and the precipitate filtered off. This is then dissolved in dilute sulphuric acid, reduced with zinc, and titrated with permanganate.

The method here indicated for the separation of sodium uranate from pitchblende or gummitte is not applicable in the case of carnotite, an ore first described by Friedel and Cumenge (*Bull. Soc. Chim.*, 1899, [3], xxi., 328). This mineral is perhaps the uranium ore which occurs most abundantly in America (see Hillebrand, *Am. Journ. Sci.*, 1900, x., 135). Carnotite is chiefly a potassium uranium vanadate of unknown composition. Different methods for the separation of the uranium from the vanadium have been suggested, but none of them seem to be quite satisfactory (Hillebrand, *loc. cit.*). The methods of Friedel and Cumenge (*loc. cit.*) and of Ohly (*Journ. Amer. Chem. Soc.*, 1902, xxiv., 19) have been examined, but the separation was not complete in either case. A modification of the method of Langmuir (*Journ. Am. Chem. Soc.*, 1901, xxiii., 688) gave satisfactory results. Langmuir's method consists in precipitating vanadium as mercurous vanadate from a nitric acid solution neutralised by addition of mercuric oxide. An excess of oxide, however, may easily

give rise to the precipitation of some of the uranium. Hence the method was altered to avoid this difficulty. It was found that no uranium separated from a feebly acid solution of uranium nitrate, if a large excess of sodium acetate was added and the solution then boiled, but that by addition of sodium acetate and mercurous nitrate to a feebly acid solution of a vanadium salt, the vanadium was completely precipitated.

The method of analysis of carnotite finally employed is as follows:—A grm. of the mineral is dissolved in a small quantity of warm dilute nitric acid, and filtered from the insoluble residue after being diluted with water. The filtrate is almost, but not quite, neutralised with sodium hydroxide, and heated to boiling. A solution of about 1.5 grm. of mercurous nitrate is then added, and a solution of 3 grms. of sodium acetate. After boiling for a short time the precipitate of mercurous vanadate separates out, and is at once filtered. The excess of mercury in the filtrate is removed by means of sulphuretted hydrogen, and the uranium is determined in the usual way in the solution obtained, which is always found to be free from vanadium.

Composition and Activity of the Ores.

Altogether twelve different specimens of uranium ores were examined.

1. A piece of pitchblende of unknown origin, found in the laboratory collection. Specific gravity, 5.4. Analysis gave the following proportions:—Uranium, 61.1; U_3O_8 , 72.0; CaO , 8.0; PbO , 3.8; Fe_2O_3 , 2.5; Al_2O_3 , &c., 4.0; insoluble, 6.5; sum, 96.9. A considerable quantity of carbon dioxide was also found.

2. Pitchblende, Bohemia	41.5 per cent uranium.
3. " North Carolina	70.8 " "
4. " Colorado	59.1 " "
5. " "	16.7 " "
6. Gummite North Carolina	54.7 " "
7. " "	51.0 " "
8. Carnotite, Colorado	13.92 " "
9. " "	34.8 " "
10. " "	5.71 " "
11. " "	16.93 " "

The four last specimens were obtained from three different sources, Nos. 8 and 9 from the same.

12. Carnotite, Utah 1.6 per cent uranium.

The radio-activity of the ores was determined in the same way and under the same conditions as in the case of the pure compounds.

The numbers given as before the time in fifths of a second, which is necessary for the discharge of the electroscope through 80 scale divisions ($\frac{1}{5}$ grm. of the substance).*

1. 75, 72, 74; 71, 71, 71; 72, 74, 73. Mean 72. $\theta = 73$.
2. 113, 113, 112; 108, 106, 108. Mean 110. $\theta = 111$.
3. 56, 56, 57; 57, 57, 59. Mean 57. $\theta = 57$.
4. 81, 81, 81; 80, 81, 80. Mean 81. $\theta = 82$.
5. 247, 246, 251, 250; 237, 237, 238. Mean 243. $\theta = 247$.
6. 92, 92, 90; 89, 90, 89. Mean 90. $\theta = 91$.
7. 84, 82, 83; 82, 82, 81. Mean 82. $\theta = 83$.
8. 337, 343, 341; 330, 332, 332; 341, 340, 334. Mean 337. $\theta = 344$.
9. 150, 151, 152; 142, 145, 156, 153, 156; 148, 151, 151. Mean 151. $\theta = 152$.
10. 778, 765; 775, 772. Mean 773. $\theta = 810$.
11. 244, 238, 244; 237, 236, 240. Mean 240. $\theta = 244$.
12. 2320, 2315; 2322; 2311. Mean 2317. $\theta = 2693$.

* It was found that the activity of carnotite, which consists of quartz sandstone mixed with uranium, in the form of a coarse powder is greater than when it is finely powdered. This effect is due to the fact that in such ores the active substance forms a layer on the surface of the sand grains. If these grains are not ground up, an abnormally small absorption of the rays exist in the interior of the material on which the carnotite is deposited.

These results are collected in the following table:—

	θ .	P.	K.
1. Pitchblende	73	61.1	22.4
2. "	111	41.5	21.7
3. "	57	70.8	24.7
4. "	82	59.1	20.7
5. "	247	16.7	24.3
6. Gummite	91	54.7	20.1
7. "	83	51.0	23.7
8. Carnotite	344	13.92	20.9
9. "	152	34.8	18.9
10. "	810	5.71	21.6
11. "	244	16.93	24.3
12. "	2693	1.60	23.3

Mean 22.1

If we take into consideration the large experimental errors which the determination of θ involves, the values of K found for the activity are as constant as could be expected. The coefficient of activity of pure uranium salts is 3.86. The mean value for the ores amounts to 22.1. Hence the ores are 5.7 times as radio-active in proportion to the uranium they contain as the pure salts. Although this conclusion only rests on the study of a limited number of substances it undoubtedly represents a universal fact.

The assumption that radium is a decomposition product of uranium leads, as is shown above, to the conclusion that every uranium ore must contain uranium and radium in a definite proportion. If, then, the radio-activity of a substance is directly proportional to the amount of radio-active substance it contains (and it has been shown that this is the case for pure uranium compounds), the activity of every uranium ore should be proportional to the amount of uranium it contains; but the activity for equal amounts of uranium and equal quantities of substance in a definite proportion should be greater for the ore than for pure uranium compounds. This is exactly the result obtained experimentally. Hence it is probable that all uranium ores contain radium in amounts which are directly proportional to the uranium they contain.

We are further led to the conclusion that radium is one of the successive decomposition products of uranium. Thus the change occurs as far as is accurately known, according to the following scheme:—

There may also be other intermediate and final products.

From Equation 2 it follows that the amount of any intermediate product is inversely proportional to its rate of decomposition. In the case of radium this is very small in comparison with the rates for UX, RaEm, or EmX. Hence the actual masses of these latter substances, which are contained in uranium ores, are very small in comparison with the mass of the radium. The extensive occurrence of helium (Ramsay, Collie, and Travers, *Journ. Chem. Soc.*, 1895, lxvii., 684) in uranium ores is a further proof of the theory here put forward. The amount of helium contained in an ore will depend among other things on its degree of diffusion throughout the mineral. This degree will doubtless vary with the nature of the ore. The relative amounts of radium and uranium in ores can be estimated as follows:—The activity of radium (together with its maximum amount of radio-active products) is about 14 million times as great as that of uranium (plus the maximum amount of UX). The coefficient of activity of the ore is 5.7 times as great as that of the pure uranium compounds, and therefore in any ore the activity to be ascribed to the radium is 4.7 times as great as that of uranium. Hence it follows that one part by weight of radium is present in an ore to about 300,000 parts of uranium. If, for example, an ore contains 35 per cent of uranium it must contain 1 part of radium in a million. These calculated values agree well with the amounts actually found.

The radio-active intermediate products, as, for example,

thorium emanation, &c., are bodies which have little or no chemical affinity. It is uncertain whether they are to be regarded as compounds of the elements. Helium, the final product of radium, is destitute of all chemical properties. On the other hand, the chemical behaviour and spectrum of radium leave little doubt that it is an element belonging to the barium group. By the results here given an attempt has been made to show that an element, uranium, by its spontaneous decomposition produces another element, radium, which has a rather lower atomic weight, and possesses very well defined and decidedly different chemical properties. Such a transformation, if actually occurring, would afford a typical example of the theory of the genetic relation of the elements to one another as suggested by Thomson ("On the Structure of the Atom," *Phil. Mag.*, 1904, [6], vii., 237; see also Lengfeld, *Journ. Phys. Chem.*, 1901, v., 639).

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING SEPTEMBER 30TH, 1904.

By SIR WILLIAM CROOKES, F.R.S.,
and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, October 10th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board, the results of our analyses of the 204 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from Sept. 1st to Sept. 30th inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 204 samples examined by us during the month, all were clear, bright, and well filtered.

The rainfall at Oxford during the month of September has been considerably below the average, only 1.26 inches of rain having been recorded. The average for September is 2.39 inches; we have, therefore, a deficit of 1.13 inches, which, if subtracted from the previous excess of 1.46 inches, leaves a total excess for the year of 0.33 inch, or 1.8 per cent above the thirty-five years' average.

Our bacteriological examinations of 382 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 382 others from special wells, standpipes, &c., making 764 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 25 samples) ..	138
New River, filtered (mean of 77 samples) ..	5
Thames, unfiltered (mean of 26 samples) ..	801
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 202 samples) ..	17
Ditto ditto highest	224
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	250
River Lea, from the East London District clear- water wells (mean of 26 samples) ..	7

Of the 305 daily samples taken from the general filter wells of the Metropolitan Water Board, twenty-five samples, or 8.2 per cent, were sterile. Eight samples, or 2.6 per cent, contained more than 100 microbes, and of these four samples contained more than 150 microbes per c.c. The eight excess samples contained an average of 159 microbes per c.c. In August eleven excess samples contained an average of 186 microbes per c.c.

The general results of the chemical and bacteriological examination of the various samples collected during September prove that the purity of the Metropolitan supply during the last month has not been equalled in recent years.

We are, Sir,
Your obedient Servants,

WILLIAM CROOKES.
JAMES DEWAR.

A NEW SEPARATION OF THORIUM FROM CERIUM, LANTHANUM, AND DIDYMIUM BY METANITROBENZOIC ACID.*

By ARTHUR C. NEISH.

(Concluded from p. 197).

Separation of Thorium from Cerium, Lanthanum, and Didymium.

THE next step was to try the separation of thorium from mixtures with cerium, lanthanum, and didymium, and then from mixtures of thorium with all three.

As before, known volumes of thorium nitrate solution were placed in beakers, known quantities of cerium, lanthanum, and didymium oxides added in the form of nitrates, then an excess of metanitrobenzoic acid was added slowly with constant stirring; the solutions were heated on the water-bath, filtered, and washed by decantation with a 5 per cent solution of the precipitant. The moist precipitate and paper were placed in a weighed platinum crucible, heated and ignited, with the precautions given above, and the thorium oxide weighed.

A separatory funnel with a capacity of 75 c.c. was found very convenient, both as a measure of the volume added and for adding the solution slowly while stirring.

The test for cerium in the filtrate by ammonia and hydrogen peroxide is of no use, as the metanitrobenzoic acid itself gives the same colour. The results given in Table III. show the efficiency of the separation.

These experiments showed that one precipitation will not separate thorium from an equal weight of cerium, lanthanum, or didymium, or from an equal or one-half the amount of all three. A nearly constant amount of each is carried down.

A re-precipitation being necessary, many methods were tried to change the thorium metanitrobenzoate to thorium nitrate. The precipitate is readily soluble in nitric acid, but on evaporating this solution a hard insoluble skin is left which encloses the impurities, making the second precipitation useless. The precipitate was dissolved off the paper into the precipitation beaker with hot dilute nitric acid (1 : 5), the paper well washed with hot water, the solution in the beaker diluted to about 150 c.c., and 25 c.c. of metanitrobenzoic acid added. Then methyl-orange was added until the solution became decidedly red, and then dilute ammonia (1 : 10) run in from a burette very slowly, with constant stirring, until the solution turns from deep red to light red or pink. The clear solution, after the addition of some ammonia, becomes opalescent, due to the re-precipitation of thorium metanitrobenzoate, and as more is added the

precipitate becomes white and flocculent, increasing as more ammonia is added.

When the precipitate becomes flocculent, the ammonia is added with great care, drop by drop, and the solution thoroughly stirred after every addition.

If the process of neutralisation were carried to the yellow tint, the other earths would precipitate.

The addition of ammonia is carried on until the red changes to pink; this marks the neutralisation of the mineral acid, and the weak acid (metanitrobenzoic) keeps the indicator pink. A very few drops more of ammonia would change the pink to yellow.

The solution of the precipitant changes methyl-orange decidedly red only when considerable quantities are added, and then the same depth of colour which mineral acids give is not produced. The 25 c.c. of metanitrobenzoic acid is sufficient to produce the pink.

At this point—the pink tint—all the thorium should be precipitated, but to ensure a complete precipitation 50 c.c. more of the precipitant are added, and the beaker heated on the water-bath as before, the solution filtered, and the precipitate washed with a 5 per cent solution of the precipitant, and either ignited and weighed or re-dissolved in nitric acid and the neutralisation repeated Table IV. shows the results with three precipitations.

The above results being satisfactory, the separation was tried on mixtures in the proportions usually found in monazite sands. Table V. shows the results with three precipitations.

It was thought that with greater dilution a closer separation could be obtained with two precipitations. Table VI. proves this to be the case.

The separation was next tried to see if one precipitation would separate thorium from cerium in the proportions in which they are present in Welsbach mantles. Nos. 3 and 4 were re-precipitated, giving slightly low results. (See Table VII.).

The Behaviour of other Elements.

Glucinum, gadolinium, yttrium, titanium, and samarium gave no precipitate, cold or hot.

Zirconium gave a white opalescence and precipitate, which increased on heating.

Erbium gave an immediate white curdy precipitate in the cold, with little change on heating; the precipitation is quantitative.

The following commoner salts were tried, although none are apt to be present in the analysis of monazite:—Calcium chloride, barium chloride, magnesium chloride, potassium-aluminium sulphate, potassium-chromium sulphate, ferrous sulphate, ferric sulphate, zinc sulphate, manganous sulphate, nickel nitrate, cobalt nitrate, bismuth nitrate, silver nitrate, lead nitrate, cadmium nitrate, copper nitrate, arsenious acid, arsenic acid, potassium-antimonyl tartrate (tartar emetic), ammonium molybdate, auric chloride, hydrochloroplutonic acid, ammonium tungstate, uranium nitrate, mercurous nitrate, mercuric nitrate, stannous chloride, and sodium stannate. With the exception of the last four, they gave no precipitate. The precipitates

with mercurous and mercuric nitrates were very heavy, white and curdy in the cold, but dissolved on heating.

Composition of the Precipitate.

The precipitate used for the determination of its composition was made by dissolving the pure thorium nitrate in water in a large beaker and precipitating with an excess of metanitrobenzoic acid. The precipitate, after heating on the water-bath, was washed by decantation, then on the filter, a Büchner funnel, with a large amount of water to make the washing complete. The precipitate was transferred in a cake to a glass plate, and dried for days in the air-bath at 115° C. When thoroughly dried, it was broken and pulverised, and again dried for two days, being frequently stirred so as to insure complete drying.

It was assumed that thorium would combine with 4 molecules of the acid as $\text{Th}(\text{C}_6\text{H}_4\text{NO}_2\text{COO})_4$.

The percentage composition calculated from this assumption is:—Th = 25.93 per cent; C = 37.46 per cent; H = 1.79 per cent; N = 6.26 per cent; O = 28.54 per cent.

The precipitate gave on analysis:—Th = 25.95, 25.97, 26.00, and 26.05 per cent; C = 37.43, 37.48, 37.32, and 37.12 per cent; H = 1.85, 1.85, 1.91, and 1.97 per cent; N = 6.42 and 6.48 per cent.

Properties of Thorium Metanitrobenzoate.

The precipitate, when dry, presents very peculiar properties; it is snow-white, very light, and is electrified. When pressed or touched with a glass rod or a brush it acts like pitch balls, being first attracted, then repelled by the rod, so that it is impossible to handle it without loss. Even the transfer of a precipitate to a platinum crucible cannot be accomplished without loss; for this reason, the precipitate is always ignited without previous drying. The thorium metanitrobenzoate is radioactive, giving, after an exposure of five days to an X-ray plate, a faint image, while the thorium oxide, produced from the ignition of the metanitrobenzoate, and the oxide separated from monazite sands by metanitrobenzoic acid, gave about four times the effect.

When thorium metanitrobenzoate is ignited, a large volume of gas is given off which burns with a sooty flame, leaving, after complete ignition, thorium oxide, snow-white and in a very loose condition. This oxide, when placed in a platinum boat inside a platinum combustion tube and strongly heated with two blast lamps, gave off white fumes, similar to those obtained by Metzger from the oxide obtained by the ignition of thorium fumarate (*Journ. Am. Chem. Soc.*, 1902, xxiv., 907). These fumes were collected in a small glass tube, but disappeared after a few minutes.

Thorium metanitrobenzoate is insoluble in water, it is easily soluble in, and prevented from precipitation by, hydrochloric, nitric, sulphuric, and acetic acids. Tartaric acid or tartrate dissolve the precipitate, from which solution the thorium cannot be precipitated either by ammonium hydroxide, potassium hydroxide, or oxalic acid. Oxalic acid dissolves the precipitate with the formation of a white, crystalline precipitate of thorium oxalate. Sodium carbonate decomposes the precipitate with the production of a flocculent precipitate, soluble in excess of sodium carbonate. Potassium hydroxide decomposes it with the formation of thorium hydroxide. It is soluble in acetone; alcohol and ether have no solvent effect.

Monazite Analysis.

The practical application of the precipitation of thorium by metanitrobenzoic acid was applied to the analysis of monazite sands. The results were checked against the two shortest and best methods, the combination method and the fumaric acid method of Metzger (*loc. cit.*). Five sands were analysed, three from Brazil and two from North Carolina.

Fumaric Acid Method.

Metzger's method was used except for the following modification: The precipitate of thorium fumarate was

dissolved in hot, dilute nitric acid (1 : 5) instead of hydrochloric acid, and instead of evaporating to dryness, which produces a compact residue incompletely soluble in water, the thorium and other contaminating earths were precipitated as hydroxides, with an excess of potassium hydroxide, and the hydroxides filtered off, washed and dissolved in hot, dilute nitric acid (1 : 5), evaporated to dryness, taken up with 40 per cent alcohol, and precipitated with fumaric acid, as before; filtered, washed, ignited, and weighed as thorium oxide. This modification eliminates any chance of the other earths being enclosed in the insoluble residue on evaporation, and also any possibility of the thorium oxide being contaminated by silica.

Metanitrobenzoic Acid Method.

Two grms. of the sand were ground to a fine powder and weighed out into a porcelain crucible, about 10 to 15 c.c. of concentrated sulphuric acid added and stirred with a small glass rod, which is left in the crucible throughout the digestion. The crucible was placed on a hot plate, heated gradually and stirred cautiously to allow the escape of bubbles of gas, which are only formed at first, and cause loss if the heating is not done carefully. The heat was increased, or the crucible moved to the hotter part of the plate until a constant cloud of sulphur trioxide was given off. When the excess of acid had evaporated, more acid was added, the contents were stirred with the glass rod and the digestion was continued. As a rule, the digestion lasted all day, since the solution of the sulphates in water was allowed to stand over night, but two results are given where the digestion lasted only three hours, so that longer digestion is unnecessary. At the end of the digestion the phosphates present in the monazite sand were all changed to sulphates; the crucible now contained about 10 c.c.; this was well stirred, and, after cooling the crucible in ice water, the mass was allowed to drop from the rod, a drop at a time, with constant stirring into a beaker containing 600 c.c. of water cooled to 0° . After all the liquid was added, the crucible itself was placed in the beaker, and the whole allowed to stand, best over night. If it is a refined sand and free from quartz, the residue on the bottom of the beaker should be small, but if there is a flocculent precipitate, it is apt to be hydrated sulphate of thorium. In this case the best thing to do is to start another portion, using greater care in adding the mass to the ice-water and to have enough free acid present to make the mass liquid enough so that when a drop of it is added to the beaker it soon dissolves, leaving a fine white powder instead of sinking to the bottom as a hard lump, as it will do if too little acid is present.

The solution was filtered into a large beaker and heated to boiling. A boiling solution of oxalic acid (saturated in the cold) was added gradually to the solution with constant stirring, a large excess being used in order to make the precipitation complete in presence of so much sulphuric acid, and also to take any zirconium into solution, which would be precipitated by the metanitrobenzoic acid; an excess can have no solvent effect whatever on the thorium present. The solution was allowed to stand, and when cool, the white crystalline precipitate, consisting of the oxalates of thorium, cerium, lanthanum, and didymium, was filtered and washed with a dilute solution of oxalic acid. It is better to allow the precipitates of the oxalates to stand many hours, or, if possible, over night. The precipitate and paper were transferred to the precipitation beaker, 10 to 15 grms. of stick potassium hydroxide added, 25 to 50 c.c. of water, and the whole heated to boiling, washing down any oxalates that were attached to the sides of the beaker. The oxalates were soon changed to hydroxides, having a silky appearance and becoming yellow on account of the oxidation of the cerium. The solution was diluted to about 300 c.c., filtered and washed with water until free from alkali. The hydroxides were dissolved into the precipitation beaker with hot dilute nitric acid (1 : 5). This solution of the nitrates was evaporated to dryness on the water-bath, moistened with

water and evaporated until every trace of free nitric acid was driven off; since the precipitate is soluble in dilute nitric acid and as nitric acid is set free in the reaction,—

all free nitric acid must be removed from the nitrates.

The nitrates were dissolved in 500 to 600 c.c. of water and 150 to 250 c.c. of metanitrobenzoic acid solution added slowly with constant stirring, and heated on the water-bath at 60° to 80° until the precipitate has all collected and settled to the bottom. It was then filtered, washed by decantation, using a 5 per cent solution of the precipitant, then placed on the filter and washed with the same solution. The precipitate was dissolved by hot dilute nitric acid (1:5) into the precipitation beaker, the paper well washed with hot water and diluted to 600 c.c.; methyl orange was added until a decided red colour was produced, then 25 c.c. of metanitrobenzoic acid. This was neutralised with dilute ammonia (1:10) until a pink tint was obtained. This is best done by placing beside the beaker another containing the same volume and amount of acid and indicator, also containing some white powder, such as pulverised quartz, and frequently stirred during the titration to give the same appearance as the contents of the other beaker. As the excess of nitric acid is neutralised, the thorium re-precipitates as metanitrobenzoate, and the solution changes from a decided red to a pink colour, due to the feeble acidity of metanitrobenzoic acid. After the pink tint was obtained, 50 c.c. more of metanitrobenzoic acid were added to insure complete precipitation. The beaker was then heated on the water-bath to from 60 to 80°, the precipitate filtered, washed, and the wet precipitate ignited and weighed, after treating for fifteen minutes with the blast-lamp.

In the analysis of monazite some difficulty was experienced in obtaining a white thorium oxide, and also in the process of neutralisation, for in making the second precipitation rapidly some experience is required to catch the proper end-point. To obviate this the following modification was used, which, though a little longer, is much easier to carry out, and insures concordant results and a pure white oxide.

After the first precipitate of thorium metanitrobenzoate was dissolved in nitric acid, instead of neutralising with

ammonia, the thorium is precipitated as hydroxide by potassium hydroxide. The potassium hydroxide at first causes a re-precipitation of the flocculent metanitrobenzoate, but a slight excess changes it to hydroxide; this is easily seen by the change from a very voluminous white precipitate to a more compact cream-coloured one. The solution was then diluted and filtered through the same paper, washed and dissolved with hot, dilute nitric acid (1:5) into the same beaker, and evaporated to dryness, dissolved in 600 c.c. of water and precipitated with metanitrobenzoic acid, and the moist precipitate ignited, and the resultant thorium oxide weighed.

This modification is recommended, as it requires no experience with the use of the indicator, and if the preceding directions are carefully carried out, a snow-white oxide will always be obtained.

Conclusions.

1. Metanitrobenzoic acid precipitates thorium quantitatively as $\text{Th}(\text{C}_6\text{H}_4\text{NO}_2\text{CO}_2)_4$ from a neutral solution of the nitrate.

2. When this precipitation is repeated, it affords a complete separation from cerium, lanthanum, and didymium.

3. This method gives as good results for thorium in monazite as the combination or fumaric acid methods, and has the advantage in that it is much shorter, and offers no difficulties in precipitation or filtration; the precipitant is not expensive and avoids the use of alcohol.

This investigation was carried out under the direction of Professor Edmund H. Miller, and I wish to gratefully acknowledge my indebtedness to him for his kind interest and advice.

THE DETERMINATION OF MOLYBDENUM IN STEEL AND IN STEEL-MAKING ALLOYS.*

By FREDERICK VAN DYKE CRUSER

and
EDMUND H. MILLER.

INTRODUCTION.

As there is difficulty in obtaining an accurate and rapid estimation of molybdenum in steel and in steel-making alloys, the following work was undertaken in order to compare the best methods now in use. It was also the object of the investigators to point out the reasons for the discrepancies in the several methods, and, if possible, to devise a rapid and accurate method which will not be affected by the impurities in molybdenum steel, or by the other metals which are sometimes added, or may in future be added. The impurities are silicon, phosphorus, sulphur, manganese, and copper; metals added are molybdenum, tungsten, chromium, and those which may in future be added are uranium and vanadium.

PART I.

In making a determination of molybdenum in steel and in steel-making alloys, the main difficulty is the separation of molybdenum from iron.

There are two general methods for this separation. The first, and most commonly used, is to separate the iron from the molybdenum as ferric hydroxide, and the second is to separate the molybdenum from the iron as sulphide of molybdenum.

After the separation of the iron the molybdenum may be determined by three different methods. First, by reduction and titration with potassium permanganate; second, precipitation of the molybdenum as lead molybdate; third, by weighing the molybdenum as molybdenum disulphide. There are several other means of estimating molybdenum, but they do not seem to merit extensive consideration;

* It was through the kindness of Mr. Whitaker, of the Welsbach Light Co., that these samples were obtained.

† From the original sample received from Professor Baskerville, not the same as used by Metzger (*Journ. Am. Chem. Soc.*, 1902, xxiv., 901). The digestion for these lasted three hours.

* Read at the meeting of the New York Section of the American Chemical Society, January 8, 1904. From the *Journal of the American Chemical Society*, xxvi., No. 6.

therefore, in comparing the different methods now used for analysing steel for the molybdenum content, the separation of molybdenum and iron will first be considered, and then the estimation of the molybdenum.

In order to test the efficiency of these two separations it was thought advisable to conduct a large number of experiments on solutions of pure salts, made up with varying proportions of iron and molybdenum. In beginning the work, two burettes were standardised against a standard 2 c.c. pipette; 7 litres of potassium permanganate solution were made up approximately N/10, filtered and standardised against pure iron ammonium sulphate, and against pure oxalic acid, the results agreeing. About 1 grm. of iron ammonium sulphate was used for the titration, and 0.3 grm. of oxalic acid, the titrations being made in duplicate. A solution of ferric chloride was made up, containing approximately 50 m.grms. of iron per c.c. This solution was standardised against the standard potassium permanganate solution. Four litres of a solution of ammonium molybdate were then made up, containing approximately A blank consisting of asbestos, water, and the same 5 m.grms. of molybdenum per c.c., and the strength of the solution determined.

As the accuracy of all the subsequent results depended upon the accuracy or the molybdenum content in this solution, it was necessary to standardise by different methods, and to have them checked.

Conditions for Precipitating Molybdenum as Lead Molybdate (Ibbotson and Brearley, "Analysis of Steel Works Materials," p. 275).—A number of determinations of the molybdenum were made, precipitating the molybdenum as lead molybdate under the following conditions:—

To 30 c.c. of the molybdate solution (containing about 150 m.grms. of molybdenum) a few drops of ammonia were added, and then 2 to 3 c.c. of acetic acid (33 per cent) in excess. The solution was diluted to a volume of from 200 to 250 c.c. and 4 to 5 grms. of ammonium chloride added; the solution was heated to boiling, and while boiling 45 to 50 c.c. of a lead acetate solution (40 grms. of crystallised lead acetate per litre) were added, then boiled for from two to four minutes, with vigorous stirring. The precipitate was allowed to settle, filtered through asbestos in a Gooch crucible, using suction, and washed by decantation with boiling water containing about 5 grms. of ammonium chloride in 200 c.c. and a few drops of acetic acid, until free from lead, the wash-water being tested with hydrogen sulphide. In washing by decantation, the washing solution was kept as hot as possible, and the solution stirred thoroughly before allowing the precipitate to settle. When free from lead, the precipitate was washed once or twice with boiling water. The Gooch crucible was heated on an asbestos plate until dry, then with the free flame, allowed to cool in a desiccator, and weighed.

Results.

Molybdate solution taken.	Weight of lead molybdate found.	Weight of molybdenum found.	Molybdenum per c.c.
C.c.	Grm.	Grm.	Grm.
30	0.5644	0.14765	0.004915
30	0.5655	0.14793	0.004931
35	0.6614	0.17302	0.004943
35	0.6579	0.17211	0.004917
40	0.7514	0.19657	0.004914

Not more than 3 c.c. of acetic acid should be added, as a large excess of acetic acid has a solvent effect upon the lead molybdate. Under these conditions the precipitate was granular, settled quickly, and filtered easily.

In order to check the results obtained by this method several others were employed.

First, precipitation of the molybdenum in an acid solution by hydrogen sulphide, at a temperature of 80° C. After an hour the solution was filtered and the filtrate re-treated as before. This was repeated four or five times, and a little more sulphide was obtained each time. The

precipitation under these conditions is incomplete unless repeated several times, as stated by Rose ("Traité Complet de Chimie Analytique Analyse Quantitative," 1862, p. 490), although used by Dohler in his method for analysing steel (CHEMICAL NEWS, 1900, lxxxii., 294). The molybdenum was then precipitated as molybdenum trisulphide in a sulphuric acid solution with hydrogen sulphide under pressure. The precipitation was complete, as stated by Treadwell, and was carried out as follows ("Kurzes Lehrbuch der Analytischen Chemie," vol. ii., p. 183):—200 c.c. of water at the room temperature, containing 10 c.c. of concentrated sulphuric acid, were saturated with hydrogen sulphide, and added to the molybdate solution in a pressure bottle. The pressure bottles used were the ordinary citrate of magnesia bottles, of about 350 c.c. capacity. After adding the solution, hydrogen sulphide was passed through until the precipitate collected; the bottles were then closed, placed in a water-bath, and heated at 100° C. for from one to two hours; after cooling, the sulphide was filtered on a Gooch crucible, and washed by decantation with water containing sulphuric acid (1:50) saturated with hydrogen sulphide. The sulphide was then converted into oxide, as described by Treadwell ("Kurzes Lehrbuch der Analytischen Chemie," vol. ii., p. 184). The results were low, 0.004733 to 0.004776 grm. molybdenum per c.c. Converting the molybdenum trisulphide to molybdenum disulphide, as used by Blair ("Chemical Analysis of Iron," 4th Edition, pp. 199–200), was attempted, with no uniform results. Evaporating the molybdate solution with dilute nitric acid in a platinum dish was then tried, adding more nitric acid, and evaporating to dryness several times, to obtain molybdenum trioxide. This gave high results, 0.005064 to 0.005095 grm. per c.c.

As these high results might be due to small traces of alkali in the ammonium molybdate, or other impurities, it was thought that the best method to separate them would be to use the electrolytic method, as given by Kollock and Smith (Journ. Am. Chem. Soc., 1901, xxiii., 669). Accordingly, different amounts of the molybdate solution were electrolysed according to their conditions of precipitation, using a platinum dish as a cathode. After the deposition was complete (on testing the solution by adding hydrochloric acid, tin, and potassium thiocyanate, no red colour was obtained), the sesquioxide was dissolved in nitric acid, evaporated to dryness, and heated to constant weight. The results checked those of the lead molybdate precipitation, i.e., 0.004908 grm. per c.c.

Having determined the strength of the molybdate solution, the potassium permanganate solution was standardised against it, under the following conditions:—Volume, 200 c.c.; acidity, 6 c.c. of concentrated sulphuric acid; temperature, 21° C. A reductor 45 c.m. long and 1.5 c.m. in diameter was used, filled with granulated zinc. The solution was poured into the reductor, and then suction applied. The solution was run through the reductor twice, followed by 200 c.c. of water, not allowing air to be sucked through during the pouring, and titrated immediately with potassium permanganate. A "blank" consisting of 200 c.c. of water and 6 c.c. concentrated sulphuric acid was run, and the permanganate required was subtracted.

Separation of Molybdenum from Iron by Precipitation as Molybdenum Trisulphide by Hydrogen Sulphide under Pressure and Titration with Potassium Permanganate.—Different proportions of molybdenum and iron were taken and treated in the following manner:—The molybdate and iron solutions were run into a pressure bottle (as previously described), and a drop or two of dilute sulphuric acid added to prevent the formation of a precipitate of ferric molybdate. Two hundred c.c. of sulphuric acid (1:20) were then saturated with hydrogen sulphide, and added to the pressure bottle, at the room temperature. Then a very rapid stream of hydrogen sulphide was passed through the solution in the bottle, which prevented the sulphide from adhering to the glass tube. The bottle was closed and placed in a boiling water-bath, and heated for from one to

two hours, then allowed to cool, emptied into a beaker, the bottle washed out with water, and the precipitate allowed to settle. The solution was filtered through a Gooch crucible by decantation, using suction, and washed with about 300 c.c. of dilute sulphuric acid (1:50) saturated with hydrogen sulphide. The precipitate was transferred to the Gooch crucible, and washed two or three times with water. The precipitate and filter were transferred to a casserole, 10 c.c. concentrated sulphuric acid, 10 c.c. concentrated hydrochloric acid, and 5 c.c. concentrated nitric acid were added, and the contents evaporated to fumes of sulphur trioxide. Dissolving the precipitate directly through the filter by different acids was tried, but without success. In evaporating to fumes of sulphur trioxide, great trouble was experienced at first by the bumping of the solution. This was finally overcome by blowing air through the solution during the evaporation. After evaporation, the solution was allowed to cool, diluted with water, and washed into a beaker. A slight excess of ammonia was added, and the solution filtered to remove the asbestos and a small quantity of ferric hydroxide. The precipitate was washed with hot water until the filtrate had a volume of 200 c.c., neutralised with sulphuric acid, 6 c.c. concentrated sulphuric acid added, and allowed to cool. When at room temperature, the solution was reduced and titrated under exactly the same conditions as used in standardising. The results obtained are given below:—

Iron taken. Gm.	Molybdenum taken. Gm.	Molybdenum found. Gm.
0.10760	0.00197	0.00189
0.10760	0.00197	0.00220
0.10760	0.00492	0.00487
0.10760	0.00984	0.01163
0.10760	0.02460	0.02374
0.10760	0.04921	0.04953
0.05380	0.04921	0.04937

0.00538	0.04921	0.04875
0.00215	0.04921	0.04969

In each case it was observed that there was iron present after dissolving the molybdenum trisulphide in the mixture of acids, and adding ammonium hydroxide. Therefore, it was thought advisable to determine whether the iron was carried down with the molybdenum sulphide, either mechanically or chemically, or whether it came from some outside source.

Two solutions containing 0.1076 gm. iron and 0.04921 gm. molybdenum were precipitated with hydrogen sulphide under pressure, and treated as already described. Having dissolved the molybdenum trisulphide, ammonia was added to the solution in excess, and the solution filtered. The precipitate remaining on the filter had the characteristics of ferric hydroxide, and, when dissolved in hydrochloric acid, gave a deep red colour with potassium thiocyanate. A blank consisting of asbestos, water, and the same amounts of acids was run under the same conditions, and gave only a trace of iron. This showed that the iron present came from the precipitation with hydrogen sulphide under pressure, and proved that it is necessary to remove it by adding ammonium hydroxide. In order to determine whether it was possible to obtain any precipitation of iron by hydrogen sulphide under pressure, two similar solutions were precipitated under the same conditions, except that no molybdenum was added, and no iron was found. In order to determine the amounts of iron present, several tests were made upon varying proportions of molybdenum and iron. The operation was conducted according to previous conditions, and the iron weighed as ferric oxide in a platinum crucible.

Molybdenum taken. Gm.	Iron taken. Gm.	Ferric oxide obtained. Gm.	Iron obtained. Gm.
0.00492	0.10760	0.00010	0.00007
0.00984	0.10760	0.00020	0.00014
0.02460	0.10760	0.00030	0.00021
0.04921	0.10760	0.00050	0.00035

Each ignited precipitate was red, and when dissolved in hydrochloric acid gave a deep red colour with potassium thiocyanate. These results indicate that the contamination is mechanical.

Separation of Iron from Molybdenum by Precipitating the Iron as Ferric Hydroxide by Sodium Hydroxide and Titrating the Molybdenum with Potassium Permanganate.—As there seemed to be some difference of opinion in regard to the use of sodium hydroxide or ammonium hydroxide in precipitating iron from a molybdate solution, it was thought advisable to determine which precipitant gives the best results. (Cf. F. T. Kopp, *Journ. Am. Chem. Soc.*, 1902, xxiv., 186; J. Brakes, *Journ. Soc. Chem. Ind.*, 1902, xxi., 832; G. Auchy, *Journ. Am. Chem. Soc.*, 1902, xxiv., 273, and 1903, xxv., 215).

Varying proportions of molybdenum and iron were taken and precipitated by adding 70 c.c. of sodium hydroxide solution (1:10) to the mixture of molybdenum and iron in a bulk of 50 to 60 c.c. acid with 2 c.c. sulphuric acid. The solution was stirred, the precipitate allowed to settle, and then filtered and washed with hot water until the filtrate had a volume of 200 c.c. The precipitates of ferric hydroxide were dissolved in dilute sulphuric acid, and reprecipitated and washed as before. The filtrates obtained were neutralised with sulphuric acid, then 6 c.c. concentrated sulphuric acid added to each, allowed to cool, reduced, and titrated as usual.

Iron taken. Gm.	Potassium permanganate required for first filtrate. C.c.	Potassium permanganate required for second filtrate. C.c.	Molybdenum found. Gm.	Molybdenum taken. Gm.
0.00215	16.15	0.05	0.05041	0.04921
0.00538	16.2	0.00	0.05041	0.04921
0.02690	16.2	0.05	0.05057	0.04921
0.05380	16.2	0.05	0.05057	0.04921
0.10760	16.1	2.00	0.05072	0.04921
0.10760	7.9	0.00	0.02458	0.02460
0.10760	3.3	0.00	0.01027	0.00984
0.10760	1.7	0.00	0.00529	0.00492
0.10760	0.75	0.00	0.00233	0.00197

All but one of the results are slightly high. In order to determine whether this might be overcome by increasing the strength of the sodium hydroxide solution used for precipitation, 0.04921 gm. of molybdenum and 0.1076 gm. of iron were precipitated in 50 c.c. bulk with 70 c.c. of sodium hydroxide solution (1:5). The amount of molybdenum found in the two filtrates was 0.05088 gm. Then 0.04921 gm. molybdenum and 0.1076 gm. iron were taken and precipitated as before, using 105 to 110 c.c. sodium hydroxide solution (1:5). The amount of molybdenum found was 0.05057 gm. This showed that the discrepancy cannot be eliminated by the addition of more of the precipitant. In order to find out whether these high results were due to impurities in the iron solution used, 0.1076 gm. of iron was taken and 2 c.c. sulphuric acid added as before, and precipitated in 50 c.c. bulk with an excess of sodium hydroxide, and treated as before. The number of c.c. of potassium permanganate required was the same as for the blank.

Separation of Iron from Molybdenum by Ammonium Hydroxide, without Boiling out the Excess of Ammonium Hydroxide, and Titration with Potassium Permanganate.—This series of experiments was carried out under the same conditions as when precipitating with sodium hydroxide, 30 c.c. ammonium hydroxide (sp. gr. 0.9) being added in excess.

Iron taken. Gm.	Potassium permanganate required for first filtrate. C.c.	Potassium permanganate required for second filtrate. C.c.	Molybdenum found. Gm.	Molybdenum taken. Gm.
0.00215	16.5	0.00	0.05134	0.04921
0.00538	16.65	0.00	0.05184	0.04921
0.02690	16.75	0.00	0.05212	0.04921
0.05380	15.9	0.5	0.05103	0.04921
0.10760	16.3	0.4	0.05197	0.04921

These results show conclusively that sodium hydroxide gives a more accurate separation of iron from molybdenum than ammonium hydroxide.

In order to determine whether the excess of ammonium hydroxide caused this increased discrepancy, ammonia was added as before, and then boiled out completely with the following results, the other conditions being maintained as given:—

Iron taken.	Potassium permanganate required for first filtrate.	Potassium permanganate required for second filtrate.	Molybdenum found.	Molybdenum taken.
Grm.	C.c.	C.c.	(rm)	Grm.
0.00215	16.1	0.05	0.05010	0.04921
0.00538	15.2	0.35	0.04839	0.04921
0.02690	15.15	0.5	0.04870	0.04921
0.05380	13.15	1.35	0.04512	0.04921
0.10760	11.20	0.8	0.03734	0.04921
0.10760	1.80	2.25	0.01260	0.02460
0.10760	0.35	0.2	0.00171	0.00984
0.10760	0.3	0.00	0.00093	0.00492
0.10760	0.05	0.00	0.00015	0.00197

These results show that boiling the ammonia out of the solution renders the results worthless. As the molybdenum solution, when treated alone, gave no precipitate, the error is due to the formation of an iron molybdate which is precipitated in a neutral solution.

This fact led to the belief that the high results obtained in the sodium hydroxide and ammonium hydroxide separations were due to the formation of a ferric molybdate, which was slightly soluble in excess of sodium or ammonium hydroxide, and thus caused high results by the iron being reduced and titrated together with the molybdenum.

Ibbotson and Brearley ("Analysis of Steel-works Materials," p. 81) state that when an alkali is added to an acidified mixture of ferric chloride and molybdic acid, a point is reached at which an insoluble basic ferric molybdate is formed, and no perfect separation of the two metals is possible until sufficient alkali has been added to decompose this compound. Also that similar bodies are formed during the separation of chromic, tungstic, or vanadic acid from iron.

It was then undertaken to find iron in the filtrate after separation of the iron by the ammonium hydroxide. Two portions containing 0.04921 grm. of molybdate and 0.1076 grm. of iron each were taken, and precipitated by ammonia, as described. The solutions were filtered, washed with water, and the filtrates (200 c.c.) were neutralised with sulphuric acid, and to c.c. of concentrated sulphuric acid added in excess. Then the molybdenum was precipitated from this solution by hydrogen sulphide under pressure. The solutions were allowed to cool, and filtered. The filtrates were evaporated to small bulk, ammonia added, and the solution filtered. The precipitates were washed and dissolved in hydrochloric acid. The filtrate from one was divided into two equal portions:—To one-half, potassium thiocyanate was added, and a red colour obtained; the other half was re-precipitated with ammonia, and re-dissolved in hydrochloric acid, potassium thiocyanate added, and a red colour obtained. The filtrate from the other was precipitated twice with ammonia, and finally dissolved in hydrochloric acid, potassium thiocyanate added, and a deep red colour obtained. The precipitate of ferric hydroxide was plainly visible. A blank consisting of 200 c.c. of water and 10 c.c. of sulphuric acid was run under the same conditions, and only a trace of colour was obtained, and no precipitate of ferric hydroxide could be seen. The precipitates of molybdenum trisulphide were dissolved in nitric, hydrochloric, and sulphuric acids, and evaporated to fumes of sulphur trioxide. The solution was allowed to cool, diluted a little, ammonia added, and filtered. The precipitates were dissolved in hydrochloric acid, and potassium thiocyanate added, and red colours were obtained. The experiment was repeated using 0.24605 grm. of molybdenum and 0.538 grm. of iron. In

precipitating with hydrogen sulphide, the hydrogen sulphide gas was passed through two plugs of asbestos, and through two wash-bottles, in order to prevent any iron from being carried over from the generating flask. The iron was precipitated twice with ammonia, ignited, and weighed as ferric oxide. The weight of ferric oxide found was 0.0005 grm. This was dissolved in hydrochloric acid, potassium thiocyanate added, and a deep red colour obtained.

These experiments show that the high results obtained are due to the formation of a ferric molybdate in small amount, which is soluble in the excess of the precipitant.

The reason that we can find the iron by the foregoing method is probably because the relative concentration of molybdenum and iron is changed, and therefore not as much ferric molybdate is formed as in the initial precipitation, thus allowing some of the iron to be precipitated by ammonium hydroxide.

(To be continued).

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 12, September 19, 1904.

Chemical Composition of Adrenaline.—Gabriel Bertrand.—The author describes a method of purifying adrenaline. He proves that the substance can be obtained pure by making two series of fractional precipitations and analysing the final fractions separately. The four analyses quoted have concordant results, and give $C_9H_{13}NO_3$ as the empirical formula. This formula was formerly proposed by Aldrich. The molecular weight (174.3, instead of 183) obtained by cryoscopic methods corresponds to the same formula.

Nomenclature of the Rosanilines.—Jules Schmidlen. The author criticises the nomenclature recently proposed by M. Baeyer as leading to very complicated terms, e.g., chloride of diaminomethylfuchsonimine for rosaniline chlorhydrate. He suggests instead a modification of the old nomenclature which retains many of the ancient terms and yet is quite exact. His system is shown in the following table:—

Ancient names.	Modifications.
Pararosaniline	Rosaniline.
Rosaniline	Rosamonotoluidine.
Fuchsin, C_{21}	Rosaditoluidine.
New fuchsin	Rosatritoluidine.
Aniline blue	Triphenylosaniline.
Crystalline violet ..	Hexaphenylosaniline.

Tetraoxycyclohexane Rosanilines. New List of Colourless Derivatives.—Jules Schmidlen.—The nomenclature in this paper is that described in the preceding abstract. In a former paper the author described the formation of tetrachlor- and tetraminocyclohexane rosaniline, the colourless addition products of rosaniline salts. He now finds that the salts of rosadi- and rosatritoluidine can take up four molecules of water when dissolved in concentrated HCl and allowed to stand. It is known that, in the case of salts forming addition products with an acid, a base, or a neutral body, their state of non-saturation is due to the presence of a non-saturated carbon atom, which can take up monovalent groups. Hence there must be present four carbon atoms with double linkings in the molecule of rosaniline salts.

Berichte der Deutschen Chemischen Gesellschaft.
Vol. xxxvii., No. 13, 1904.

Fluorescence. The Ring System of Benzene.—Hugo Kauffmann.—The author examined the effect of Tesla currents upon substances belonging to various classes, e.g., carbohydrates, phenol ethers, amines, &c., using either alcohol or acetic acid as solvent, and found that violet fluorescing substances yield vapours which become luminous under the influence of Tesla currents, and the colour of the luminescence agrees with that of the fluorescence. From this experimental result it follows that the ring in violet fluorescing benzene derivatives is in the same condition as in those substances which give a violet fluorescence under the influence of Tesla currents (X or D condition). Two points are to be taken into consideration in studying all luminescence caused by radiant energy—absorption and emission. Thus, from experimental results we see that the emission is the same in fluorescence and in luminescence caused by Tesla currents, and that in both cases it depends upon the condition of the benzene ring. This is not the case with the absorption. In the Tesla experiments the reason for the absorption lies in the benzene ring itself, but in fluorescence, which is caused by absorption of ultra-violet light, some other reason must be sought. Certain groups must be present in order that a substance may fluoresce, e.g., the carbethoxyl group. Thus the aniline ring gives no fluorescence though it luminesces, whereas anthranilic acid ester both luminesces and fluoresces. In investigating the phenomenon of fluorescence absorption and emission must be examined as separate phenomena. By studying the fluorescence of dihydrocollidine dicarbonic acid diethyl ester it may be proved that the violet emission is connected with the existence in the ring of parallel double bonds.

Metallic Nitroso Compounds.—V. Kohlschütter and M. Kutscheroff. —*Cupric Nitroso Compounds.*—On electrolysing concentrated solutions of copper chloride part of the copper migrates from the cathode. The quantity of copper which is transferred to the anode rapidly decreases with dilution, and the negative transport numbers soon assume their normal values. This phenomenon is to be ascribed to the formation of the cupric salt of a cupric-hydrochloric acid with the anion, CuCl_4'' . This anion is only stable in presence of excess of chlor ions, and with increasing dilution it decomposes as follows:—

In studying the formation of cupric nitroso compounds the authors found that in aqueous solution the quantity of NO absorbed by copper chloride is never very large, and rapidly diminishes with dilution. Absorption only takes place within the limits of concentration in which the transport numbers were found to be abnormal, i.e., in green solutions, and ceased entirely as soon as the dissociation became normal. Hence the power of cupric chloride solution of absorbing NO is connected with the formation of complex ions. Since addition of chlorides increases the absorption in solutions containing the same quantity of copper chloride, it is clear that it is specially the anions containing copper which take up the nitric oxide, for an excess of chlor ions favours the formation of the complex anions. The examination of the phenomenon of the absorption of nitric oxide by copper chloride dissolved in various other solvents all goes to show that the absorption always depends upon anions containing copper and never upon the copper cations. The solutions which absorb NO are never blue, but always green or brown. These latter contain complex anions, or cations, to which negative residues are still attached. All solutions give up their NO on standing in the air or on dilution with water. Solid copper salts do not absorb the gas.

Rapid Method of Distinguishing Rosaniline and Pararosaniline.—Rudolf Lambrecht and Hugo Weil.—Commercial rosaniline dissolves completely on warming in 20 parts by volume of 30 per cent hydrochloric acid. No

crystals separate out from the solution even on standing for some days, while pararosaniline on addition of the same quantity of hydrochloric acid forms the difficultly soluble chlorhydrate which crystallises out on cooling. If only $\frac{1}{2}$ per cent of pararosaniline is present in commercial rosaniline, after twelve hours brown crystals appear, while larger quantities, amounting to 5 to 10 per cent, give crystals immediately on cooling. The brown pararosaniline chlorhydrate thus separated becomes dark green after standing for six weeks over caustic lime, and then contains 3 molecules of hydrochloric acid besides water of crystallisation. It is noteworthy that commercial rosaniline on solution in less than 20 parts of hydrochloric acid after standing gives crystals of polychlorhydrate.

A New Molybdenum Carbide, MoC.—H. Moissan and M. K. Hoffmann.—A mixture of 25 grms. of coarsely powdered molybdenum and 25 grms. of aluminium in small pieces with 0.2 gm. of petroleum coke was heated in a charcoal crucible in an electric oven for not more than three minutes, a current of 500 amperes and 100 volts being employed. The crucible must be quite closed with a layer of charcoal. On cooling and breaking up the molten metallic mass, crystals of a dark colour were seen embedded in yellow laminated aluminium carbide. The metal was coarsely powdered and treated in the cold with a mixture of concentrated caustic soda and potash, when a gas was energetically evolved. The metal was then digested with caustic alkali for three or four days on the water-bath, the alkali being renewed from time to time till no more hydrogen was evolved. A black crystalline powder then remained, which was heated on the water-bath for twenty hours with dilute sulphuric acid (3 parts concentrated acid to 1 part water), washed with cold concentrated hydrochloric acid, and finally with water, and dried at 100°. Thus a mixture of graphite and a grey crystalline, much heavier, powder was obtained, and the latter was separated from the graphite first by means of a sieve and then by the addition of bromoform. The molybdenum carbide, MoC, thus obtained is a grey powder which is seen under the microscope to consist of prismatic glittering crystals. Its density is 8.40 at 20°. It easily scratches glass and quartz but not ruby. It is not attacked at a red heat by pure dry hydrogen nor by steam at 600°. It burns in fluorine, forming CF_4 and a white molybdenum fluoride. At a red heat chlorine converts it into molybdenum chloride and amorphous carbon. Heated in presence of air or oxygen it forms molybdenum trioxide and carbon dioxide. It is scarcely attacked by boiling aqueous hydrochloric acid, reacts very slowly with concentrated hydrofluoric acid, and is decomposed by boiling concentrated sulphuric acid and by nitric acid in the cold.

Phosphorescing Substances.—K. A. Hofmann and W. Duca.—The authors found that among 15 preparations of blende made from perfectly pure zinc ammonium sulphate not one phosphoresced, even intense Becquerel rays only causing feeble luminescence. But commercial zinc chloride, treated strictly according to Henry's directions, gave visible luminescence on exposure to daylight or Becquerel rays. The qualitative analysis of the zinc chloride used showed the presence of the following impurities:—Small quantities of lead, nickel, iron, calcium, and silicon, and relatively large amounts of potassium, sodium, and magnesium, and the addition of these substances to pure zinc ammonium sulphate gave luminescing blends. For a blende of very strong yellowish green luminescence the authors added 100 c.c. of 8 per cent aqueous ammonia to a solution (slightly acidified with sulphuric acid) of 20 grms. of the purest zinc ammonium sulphate, 5 grms. of sodium chloride, and 0.2 to 0.5 gm. of crystallised magnesium chloride in 400 c.c. of distilled water and allowed to stand for twenty-four hours; the clear filtrate was saturated with sulphuretted hydrogen, the sulphide collected and dried at 100° without previous washing. It was then powdered, and ignited in a covered porcelain crucible for thirty minutes in a larger vessel placed in a Perrot or

Rössler gas-oven. This crystalline pale yellow preparation is very strongly affected by Becquerel rays, cathode rays, arc light, or daylight. Sunlight through blue, violet, or green glass acts very strongly, while yellow or red light completely stops the phosphorescence. The blende thus prepared luminesces under the influence of a strongly active substance. If pure magnesium sulphate and pure potassium chloride are used instead of magnesium chloride and sodium chloride the same effect is obtained, but neither pure alkali chloride nor pure magnesium salt alone is sufficient. Possibly by admixture of alkali chloride the crystallisation of the sulphide at white heat is expedited, for which reason repeated heating with an equal weight of sodium chloride has a favourable effect upon the power of becoming luminescent. The addition of magnesium salts removes impurities, such as arsenious acid or antimony oxide, from the ammoniacal solution, but the authors could not get phosphorescing preparations from the purest zinc ammonium sulphate, which contained no trace of arsenic or antimony, or any impurity, without the help of magnesium or alkali salt. Hence the luminous effect must be due to the magnesium directly, or to an admixture contained in the magnesium salt. If the latter were the case, the filtrate from the ammoniacal mixture precipitated with sulphuretted hydrogen should be free from, or at any rate poorer in, the active mixture, as this would be precipitated with the zinc sulphide. But with such a filtrate, using the purest zinc ammonium sulphate and ammonia as described above, the authors obtained a preparation as active as before. Hence, they assume that the magnesium salt remaining in the zinc sulphide on filtration as well as the alkali chloride is necessary for the preparation of the strongly phosphorescing blendes. The presence of some metals (one part per thousand), e.g., iron, nickel, cobalt, bismuth, chromium, copper, reduces the luminescence, while others, e.g., zinc, selenium, manganese, and cadmium, have the opposite effect. The phosphorescing blendes show no trace of radio-activity.

MISCELLANEOUS.

St. Louis Exhibition Awards.—Messrs. A. Boake, Roberts, and Co., Ltd., Stratford, have received a cable from the St. Louis Exhibition intimating that they have been awarded Grand Prize, 2 Gold Medals, and a Silver Medal. Their exhibit was composed of Chemicals (principally sulphites and phosphates), Materials for Brewing, and Essences for aerated waters and confectionery purposes.

NOTES AND QUERIES.

Plastic Materials.—In an article by S. S. Sadtler (CHEMICAL NEWS, vol. xc., p. 184 *et seq.*) I find several recipes for plastic materials. Would any of those recipes be of use to make underground pipes? Would the recipe for powdered anthracite coal and molasses require much pressure, and what would be a suitable binder to use? I want, if possible, to get a material that can be moulded without pressure.—HILLIARD STEPHENS.

MEETINGS FOR THE WEEK.

FRIDAY, 28th.—Physical, 5. "An Interference Apparatus for the Calibration of Extensometers," by John Morrow and E. L. Watkin. "A Sensitive Hygrometer," by Dr. W. M. Thornton. "Note on a Property of Lenses," by Dr. G. E. Allan.

UNIVERSITY OF BIRMINGHAM.

ASSISTANT LECTURER AND DEMONSTRATOR IN
CHEMISTRY.

The Council invites applications for this Appointment.

The stipend will be £150 per annum. The Candidate selected will be required to enter on his duties at the earliest possible date. Further particulars may be obtained from the undersigned, to whom applications, accompanied by testimonials, should be sent not later than November 7th, 1904.

GEO. H. MORLEY, Secretary.

UNIVERSITY OF GLASGOW.

ADDITIONAL EXAMINERSHIPS.

The University Court of the University of

Glasgow will shortly proceed to appoint the following additional Examiners:—

(a) For Degrees in Arts and Science.—One Examiner in MATHEMATICS. Annual salary, £70.

(b) For Degrees in Arts, Science, and Medicine.—One Examiner in NATURAL PHILOSOPHY (including PRACTICAL PHYSICS). Annual salary, £70. Candidates should be qualified both on the Mathematical and Experimental side.

One Examiner in CHEMISTRY. Annual salary, £50.

The appointments will be for three or four years from January 1st, 1905, and, in addition to the above-mentioned salaries, hotel and travelling expenses will be paid.

Candidates should lodge twenty copies of their application and testimonials with the undersigned on or before NOVEMBER 12th, 1904.

ALAN E. CLAPPERTON,
Secretary, Glasgow University Court.

97, West Regent St.,
Glasgow.

THE CHEMICAL NEWS.

VOL. XC., No. 2344.

NOTES ON THE FRACTURE OF STRUCTURAL STEEL UNDER ALTERNATING STRESSES.*

By JOHN OLIVER ARNOLD,
Professor of Metallurgy, Sheffield University College.

THE efforts of steel metallurgists and engineers to obtain scientific control over the mechanical properties of steel used for structural engineering purposes, although attended with much success, have nevertheless presented certain unfortunate features of failure. Thirty or forty years ago, it was claimed, apparently with reason, that if the chemical constituents of mild steels were identical, their mechanical properties were necessarily similar. But as experience extended, it soon became evident that steels registering practically the same chemical analyses gave astoundingly different mechanical tests. The next stage of research led to the enunciation of the generally accepted idea that steels having a good chemical composition correlated with satisfactory tensile and bending tests, were thoroughly reliable. But the advent of high speeds placed engine parts under rapidly alternating tensile and compression stresses, the reversals being in some instances at the rate of 800 per minute. Under these new conditions the sense of security ensured by a good chemical composition and satisfactory static tests, was rudely disturbed by the fact that steel in a relatively small number of cases was liable to fracture far below its elastic limit, more after the manner of glass than of a ductile metal.

These facts led to a remarkable development of the micrographic method of examining steel. The results obtained have thrown considerable light upon the matter, but after fifteen years' correlative research the inexorable logic of facts compels the author to state with regret that in connection with this particular matter the microscope in its turn has, to a considerable extent, broken down in its attempt to solve that mystery of steel, of all others the most important practically, namely, the cause and prevention of its sudden rupture under vibration and alternation, two phenomena probably closely allied. The author here wishes to emphasise and reiterate the fact that he is discussing steels possessing great toughness and ductility under ordinary static tests.

To pass from generalities. The author, through the kindness of his friend, Mr. J. T. Milton, Chief Engineer of Lloyds, is enabled to publish, with a certain degree of reserve, important facts ascertained during a two years' research carried out with the assistance of his friend and colleague, Mr. Andrew McWilliam, A.R.S.M., at the University College of Sheffield, under instruction from Lloyds' Committee.

To select one instance. The shell plates of the boiler of a Colonial cruiser, split longitudinally from end to end, under the hydraulic test. The fractured plates were about 1 inch thick, and each weighed nearly three tons. The average analysis of the plates was about as follows:—

Carbon		0.20
Silicon		0.02
Manganese		0.50
Phosphorus		0.04
Sulphur		0.04
Copper		
Arsenic		Very low

Of course the above analysis is beyond reproach. Pieces from the fractured plate, bent double, and closed right up

* Read before the British Association (Section G), Cambridge Meeting, 1904.

under violent hammering, without any sign of flaws. The average tensile tests registered about:—

Elastic limit		15 tons per square inch
Maximum stress		29 tons per square inch
Elongation		29 per cent on 2 inches
Reduction of area		50 per cent

The above mechanical tests leave little to be desired. The microscopical structure showed a distinct and unusually sharp segregation of the pearlite and ferrite, the latter being angular and intensely crystallised. It was also large in pattern, and frequently occurred in those long white lines, rich in sulphur and phosphorus, which are technically known as "Ghosts."

In the early stages of the research it was thought that the sharp crystallisation might be regarded as an effect due to that cause which produced also the effect of brittleness. As will be seen presently, this theory was decisively negated by subsequent experiments. In order to measure the mechanical brittleness incapable of being detected by ordinary static or bending tests, the author caused to be devised a machine in which the test piece is placed under rapid and severe alternating stresses slightly beyond its elastic limit, the amount of strain being necessarily relatively small. The number of alternations are registered by a counter, adjusted to zero for each test. The rate of alternation can be varied at will, and in the near future these data will be supplemented by a record of the energy expended per test piece, ascertained by means of a delicate integrating Watt meter.

This method of testing (which practically carries out the almost impracticable Wöhler test in one or two minutes) has already thrown important light on the obscure phenomena under investigation, and has also exhibited remarkable delicacy. These facts are proved by the data now submitted to the section by the author.

In preliminary tests on standard English acid open hearth boiler plate steel the remarkable fact was noted that in all probability the resistance of structural steel to rupture under rapidly alternating stresses is inversely proportional to the rate of alternation. This law, if fully established by the exhaustive experiments now being carried out at the Sheffield College, demands careful attention from every engine designer. The following figures indicate concretely the data upon which the author provisionally enunciates the law. The subjoined table has reference to alternating shock bending tests carried out on a good boiler plate steel, the test bars being $\frac{3}{4}$ inch square, and the bending force being applied $\frac{1}{4}$ inches from the line of maximum stress, with a range of $\frac{1}{16}$ inch each side.

Mark	Rate of alternation.	Number of alternations necessary to complete fracture.
S 1	168 per minute	1330
S 2	" "	1456
S 3	" "	1352
S 4	" "	1361
Mean		1375
S 5	266 per minute	860
S 6	" "	870
S 7	" "	916
S 8	" "	868
Mean		878

Whilst the above results exhibit considerable concordance, those obtained from the fractured boiler plate were so erratic that for a time the author was almost in despair—when the curious clue to the situation presented itself, that one side of the plate was brittle, and the other tough under alternating stresses. This theory, about to be put to a most careful experimental test, but in the meantime the following data are, in all probability, substantially accurate:—

Mark.	Rate of alternation per minute.	Number of alternations endured.	Heat treatment.	Probable position of test-piece.
L 3	168	420	Heated to 950° C. and cooled in air.	Inside
L 4	168	1232		Outside
L 7	168	1378	Oil quenched from 950° C.	Outside
L 8	168	694		Inside
L 11	266	433	As received.	Inside
L 12	266	864		Outside
L 18	266	260	Heated to 950° C. and cooled in air.	Inside
L 19	266	500		Outside
L 20	266	388	Annealed, heated to 950° C., slowly cooled.	Inside
L 21	266	781		Outside
L 22	266	630	Oil quenched from 950° C.	Outside
L 23	266	240		Inside
L 26	266	400	Water quenched from 900° C.	Doubtful
L 27	266	336		Doubtful

The somewhat disconcerting lessons to be drawn from the above table are:—1. That once a steel has assumed decisive brittleness in alternation, it cannot be restored by heat treatment of any kind, short of re-melting. 2. That the injury to this steel was on one side of the plate, and hence due to unskilful re-heating of the ingot, and not to an improper casting temperature, since the latter must necessarily have affected every portion of the plate. A third and still more regrettable confession has also to be made, namely, that the microstructures of the pairs, including both brittle and tough steel, were in all respects identical, though, of course, that of each pair varied with the heat treatment to which they had been subjected.

The author wishes, finally, to record some delicate and interesting tests obtained from an inch plate of mild steel bent over a radius considerably shorter than that of a large boiler, namely, about 2 feet. In such a plate the inside radius will represent a line of maximum compression stress, the outside radius a line of maximum tensile stress, and a radius exactly between the two will touch a neutral line. (See accompanying figure).

If from the apices of two V's, x y, progressing inwards and outwards, lines are drawn to the inner and outer circumferences, these V figures will qualitatively represent the increasing intensity of the stresses at increasing distances from the neutral line. As to the quantitative value of these angles, the author has no practical data. The following table records the influence of stress in deteriorating the metal next the inner and outer radii, and also that immediately adjacent to the neutral line.

Mark and position.	Rate of alternation per minute.	Number of alternations endured.	Remarks.
O	266	916	Mean of ten tests.
I	266	996	" "
M	266	1067	" "

It will be seen that, in its resistance to fracture under alternating stresses, the portion of the plate in tension is inferior to that in compression; whilst the steel about the neutral line is superior to that next the inner radius.

All the results recorded in this paper are preliminary, having been carried out on an extemporised machine. A standard machine has now been erected at the Sheffield College, from which the author hopes to obtain in the near future standard data as to the influence of sizes and shapes of test pieces, length of stroke, rate of alternation, and the correlation (if any) between these data and the energy necessary to produce fracture.

PRESENT PROBLEMS OF ORGANIC CHEMISTRY.*

By W. A. NOYES.

THERE is a strong tendency on the part of some chemists, at the present time, to claim that chemical science in the true sense includes only such portions of our knowledge as can be stated in accurate mathematical terms. One distinguished representative of this school of chemistry has said, "It is not in the province of science to explain phenomena," and another has written, "It is not a part of its ultimate object (*i.e.*, of natural science) to acquire knowledge in regard to mentally conceived existences, such as the atoms of matter, or the particles of luminiferous ether, which are of such a magnitude and character as to lie far beyond the limits of human perception." I think that nearly all of those now actively engaged in working over the problems of organic chemistry would dissent strongly from these statements. Long experience in dealing with the cumulative, non-mathematical evidence upon which our knowledge of chemical structure is founded has led to a very firm conviction that human knowledge is not bounded by the limits of sense-perception. We are inclined rather to the view that, while there are, undoubtedly, many things which will always remain beyond any direct cognisance of our senses, yet, so far as these have a real existence, we may in the end secure, regarding them, very practical and positive knowledge. It is impossible to conceive that those theories with regard to structure which have guided the work of thousands of chemists for the last fifty years do not in some measure express the actual truth with regard to atoms and their relation to each other in organic compounds.

Let us follow, for a few moments, in very brief outline, the steps which have led to the present standpoint. So far as the matters which interest us most are concerned, there was practically no knowledge of organic chemistry before the nineteenth century. The first steps were, of course, the preparation of pure substances and the development of accurate methods of analysis. In both of these fields Liebig was the great master. The formulae which were calculated were at first of little value except to check the accuracy of the analyses and as a simple expression for empirical composition. I need not dwell on the confusion which existed throughout the first half of the century because there was no agreement as to the basis for molecular weights or atomic weights, nor upon the large part played by the study of organic compounds in finally clarifying the view of chemists upon these matters. Yet, in spite of this confusion, two discoveries of fundamental importance date from this period:—(1) That the empirical composition alone does not fix the nature of a compound, *i.e.*, the fact of isomerism; (2) that certain groups of atoms may remain together in passing from one compound to another through a whole series. The first fact furnishes one of the strongest reasons why an empirical formula for an organic compound is not enough, and the second fact furnishes the most important experimental basis at the foundation of our structural formulae.

The studies of this period furnished a knowledge of the empirical composition of many natural products and of the products obtained from these by oxidation, reduction, and the action of various agents. But while some might, perhaps, be inclined to look upon this mass of empirical knowledge as the most valuable acquisition of that time, and to think that the theories in vogue were so imperfect or erroneous as to be of no value, such a view is certainly superficial. There were plenty of chemists in that day, too, who were ready to decry theories which seemed to them worthless, and it is interesting to read to-day what the great Laurent said upon this matter. He wrote in 1837 (*Liebig's Ann. de Chem.*, xxii., 143):—"If I could believe that the purpose of my work was only to find a few new compounds, or that it would end in my being able to

* Read at the International Congress of Arts and Science in St. Louis, September 21, 1904. From *Science*.

say that there is an atom more or less in this compound or that, I would give it up on the spot. Only the desire of finding an explanation for some phenomena and of proposing some more or less general theories can give me the courage to follow a course in which I have found so little encouragement and where I have met with so many obstacles to overcome." Any one who has followed the story of how the older theories of radicals paved the way for the theory of types, and of how the typical formulae were so easily transformed into structural formulae when the fact of valence was once grasped, cannot fail to see that the larger and fuller view is an outgrowth from the earlier theories. And we must acknowledge that Laurent was right, and that the theories upon which he was working were of vastly more importance than the mass of empirical facts which furnished him with their scaffolding.

Do not misunderstand me. There were two theories of radicals at that time—one which devised radicals in the study which should accord with the electro-chemical theories held at the time, and which did not attempt to secure evidence of their existence from the conduct of the compounds containing them, another which kept in much closer touch with the facts discovered in the laboratory. It was only the latter theory which contributed much to the growth of our knowledge. A theory which cannot secure for itself a sound experimental basis is, of course, of only ephemeral value.

These, then, are the steps which have led to our present standpoint in organic chemistry:—The discovery of isomerism, the discovery of radicals, the older radical theory, the theory of types, the establishment of true molecular weights, the discovery of the fact of valence, the determination of structure.

I think that all workers in organic chemistry will accept the following as a conservative statement of our present knowledge:—(1) That in organic compounds, at least, each atom is attached *directly* to only a limited, small number of other atoms; (2) that in the sense of the order of the successive direct attachments, the structure of a very large number of compounds is known with a degree of probability that amounts to practical certainty.

This brings me to the task which has been set, an attempt to outline the problems which lie before us in the further development of our science.

In the first place there is still much to be done to extend our knowledge of compounds found in nature. This field is much less cultivated, relatively, than was the case sixty years ago. There has been good reason for this because of the problems of absorbing interest which have arisen in the preparation and study of new compounds, and in the extension of our knowledge of old ones. But there must still remain many compounds to discover, both among animal and vegetable products. On this side organic chemistry resembles the descriptive sciences of botany, zoology, and mineralogy. And just as botanists think it worth their while to secure as complete a description as possible of the plants to be found on the earth, so it lies in our province to isolate and identify the carbon compounds of the animal and vegetable worlds—with the difference that in our case each compound, new or old, may be the starting-point for the preparation of an almost endless number of others. But here most of us recognise that unless a compound has some further interest than that it is new it is not worth the time taken in its preparation. I am afraid, however, as we look over the pages of our journals there is too much evidence that not every one lives up to this view. Our ever-increasing army of nascent doctors must needs have something to do, and it is so easy to make new compounds and so difficult to find something new of larger scope and really worth the doing.

There still remains much to do in the determination of the structure of compounds which have long been known. The study of a single compound often involves an incredible amount of work. Baeyer worked with indigo for fifteen years before his labours were crowned with a successful synthesis, and twenty years more and the work

of very many chemists were needed before the scientific achievement could become a commercial success.

It was nearly twenty-five years after the first structural formula was proposed for camphor before Bredt was fortunate enough to suggest the true arrangement of its atoms, and it was ten years longer, and required in all the work of more than fifty chemists, before Bredt's suggestion was confirmed by Komppa's beautiful synthesis.

More than thirty formulae were proposed for camphor, and those who think little of organic chemistry have some reason if they say that we jump at conclusions too hastily and propose too many formulae that are mere guesses. Some might even say that the last formula is not worth much, but those who have followed the matter know that step by step we have arrived at an almost positive certainty even in this complex problem.

The final solution of a problem with regard to the structure of a compound of natural origin is not usually considered to have been satisfactorily attained until its synthesis has been effected. Those who have attempted work of this character know that months or even years of work are frequently spent to obtain the synthesis of a single compound. In spite of the wealth of methods at our command—a wealth so great that it is often very difficult to select between several which are equally unpromising—it is evident that these methods of synthesis need improvement at many points. Not only do we need new and better methods, but many old methods require further study to disclose why they succeed in some cases and fail in others, and to secure a fuller knowledge of secondary reactions which often occur. As recent remarkable achievements in this field of synthetic methods may be mentioned the brilliant results obtained by Grignard with magnesium compounds, Bouveault's elegant new solution of the old problem of transforming an acid into the corresponding alcohol, and Scheuble's reduction of the amides of bibasic acids to the corresponding glycols.

Work along the lines suggested needs to be done in order to fill out and complete our knowledge in a systematic way, and occasionally work along such lines is rewarded by results of epoch-making significance, as when Gomberg discovered triphenylmethyl in his endeavour to prepare hexaphenylethane. Such work is not likely, however, to greatly advance our insight into the real nature of carbon compounds, and we all feel that there are far more fundamental problems which demand attention.

As outlined above, the theories of valence and of structure now universally accepted imply a certain amount of knowledge of the arrangement of atoms in space. So far as the original and fundamental conceptions are concerned, however, this knowledge is quite vague. The much more definite conception proposed by van't Hoff, and in a somewhat different manner by Le Bel, is of course familiar to you all. In discussing any hypothesis it is always important to have clearly before us the facts upon which it is based. As I have already hinted, I believe that the theory of valence and the theory of structure, in the sense of a sequence of atoms within the molecule, are supported by our knowledge of such a vast accumulation of consistently interrelated phenomena that we are justified in believing that we have positive knowledge with regard to the structure of the molecules of organic compounds. I am as ready as any one to demand that every theory, no matter how old or how universally accepted, shall be continually brought back to the test of agreement with experimental facts, but I am not willing to admit that we may not, in the end, acquire positive knowledge by the process of inductive reasoning.

Assuming, then, the fact of a knowledge of the sequence of atoms in organic compounds, we have this basis for van't Hoff's hypothesis:—1. When four unlike atoms or groups are combined with a single carbon atom, optical activity results in such a manner that there may always be found two compounds having identical sequence of the atoms within the molecule, and exactly equal rotary power but of opposite signs. 2. That when two adjacent carbon atoms are combined, each with three unlike groups, two

compounds may result which, while optically inactive and having the same sequence of atoms, still differ in physical properties. An illustration of this is found in racemic and mesotartaric acids. 3. Rings containing five and six atoms are formed with especial ease, those containing three, four, and seven atoms less readily, and rings containing more than seven atoms are scarcely known. 4. Derivatives of cyclopropane, cyclobutane, cyclopentane, and cyclohexane, having two substituents combined with different carbon atoms, often exist in two isomeric forms in which the sequence of the atoms is the same. 5. Derivatives of ethylene often exhibit a similar isomerism.

Assuming as true that we have acquired a knowledge of the sequence of atoms in carbon compounds, the facts which I have enumerated lead almost inevitably to the corollary that the four atoms attached to a given carbon atom are arranged in approximate symmetry around the centre of that atom for their position of most stable equilibrium. The relation between this conclusion and the theory of the sequence of atoms in carbon compounds, or what is ordinarily understood as structure, is very similar to the relation between the atomic theory and Avogadro's law. If we accept the atomic theory, there seems to be no rational escape from the acceptance of Avogadro's law. In a similar manner, if we accept the theory of the sequence of atoms in carbon compounds, there seems no reasonable possibility other than that van't Hoff's hypothesis is true in its broad outlines.

I hope I may be pardoned here for a brief digression. I am aware that Franz Wald (*Zeit. Phys. Chem.*, 1897, xxiv., 633) believes that he can give a satisfactory explanation of the laws of fixed and multiple proportion, and of combining weights without the aid of the atomic theory, and that Professor Ostwald, in his recent Faraday lecture, has accepted and expanded the same thought (*Journ. Chem. Soc.*, xxv., 506). I will say frankly that their reasoning does not appear to me conclusive. Ostwald defines a chemical individual as "a body which can form hylotropic phases within a finite range of temperature and pressure" (*Journ. Chem. Soc.*, xxv., 515), and deduces from this the fact that a given hylotropic phase must have a fixed composition. He appears to forget that the existence of these hylotropic phases implies that the properties of matter are discontinuous, or, in other words, that there is a finite number of hylotropic bodies, one of the facts for which the atomic theory gives an explanation.

There is another characteristic, too, of a chemical compound which all chemists will agree is at least as important as that it shall consist of a "hylotropic phase." This is that the compound must not only have a fixed composition, but this composition must bear a definite relation to those numerical quantities which represent the proportion in which each element of which it is composed always combines with other elements. I need hardly add that these numerical quantities are so deeply seated in the properties of matter that, having adopted a unit, all chemists are absolutely agreed in selecting one, and only one, such quantity for each of the well known elements.

In attempting to deduce this law of combining weights Ostwald assumes that three elements form the compounds AB, AC, BC, and ABC, and adds:—"There shall be but one compound of every [each] kind." With this assumption, his reasoning may be sound, but I fail to see how it applies when we find ten thousand compounds ABC instead of one. The case which he supposes is so far theoretical that I have been unable to find an actual case where the compound ABC can be formed, both by the union of AB with C, and of AC with B.

(It is quite possible that such an illustration may be found, but, in any case, Professor Ostwald's deduction can not be made to apply to those cases in which the compound ABC does not exist, nor to those cases where the compound ABC cannot, even theoretically, be supposed to consist in turn of a known compound AB combined with C, and of another known compound AC combined with B. Such cases are common because of the fact of valence. In

its simplest form the law of combining weights is quite independent of the existence of the compound ABC, and may be stated thus:—"If the composition of two compounds AB and BC has been determined, the composition of a series of compounds between A and C can be predicted, and a compound which does not belong to this series has never been discovered." A still more general statement of the law, and one which includes, by implication, all of those facts which are used in the selection of atomic weights, is given above. In that form it is more properly called the law of atomic weights).

But I have taken too much time with a matter which is aside from my main purpose. Before leaving this topic I must add, however, that I have used the phrase "Avogadro's law" advisedly in spite of the fashion set by some chemists of calling it Avogadro's hypothesis.

(Two reasons may be given for this usage. My own view is that we have, by a process of inductive reasoning, acquired much positive knowledge of the existence of atoms and molecules that the expression "Avogadro's Law" is fully justified. But even if we admit the contention of those who think that the atomic theory must always remain an unproved hypothesis, it is possible to frame a definition of the word molecule which would be merely a generalised statement of those empirical facts which lie at the basis of our atomic and molecular theories. Such a generalised empirical definition must, of course, be very complex, but it would not include the concept of discrete particles. Yet it will be still true of these empirically defined molecules that equal volume of gases contain equal numbers under the same conditions of temperature and pressure. For instance, the term gram-molecule may be considered as a purely empirical generalisation, and it is true that a gram-molecule of one gas occupies the same volume as a gram-molecule of any other other. But this is, in essence, Avogadro's Law).

I remarked a few moments ago that the facts which have been outlined almost compel us to the acceptance of van't Hoff's hypothesis in some form. It is of the utmost importance for us to recognise, however, that we are here at the very confines of our present knowledge, and that we must, at every step, bring ourselves back to the rigorous test of experimental fact. In accepting the hypothesis we are not compelled to consider molecules as set pieces of mechanism; on the contrary, there is strong reason for thinking that the positions assumed by the atoms are positions of dynamic and not of static equilibrium. While there have been many speculations in the matter, we have no strong reason for assuming, as yet, any definite shape for the carbon atom, nor even that there are within it definite points of attraction for other atoms. All that seems to be thoroughly established is that for their position of most stable equilibrium, the four atoms or groups attached to a given carbon atom are arranged in approximate symmetry around its centre. I say *approximate* symmetry, because the existence of compounds containing rings of three and four carbon atoms demonstrates that the symmetry is not always absolute, and makes it probable that in cases where the four atoms or groups are unlike the symmetry is also imperfect. So far as I am aware no fact inconsistent with this fundamental conception is known, while very many facts about optically active and cyclic compounds find in this conception the only satisfactory explanation which has thus far been given. It is true also that many facts with regard to optically active compounds indicate that when one group is exchanged for another the exact configuration is often retained, or, in other words, the entering group takes the same position with regard to the other three atoms or groups as was held by the group which was displaced. The manner in which it has been possible to work out consistently the complex relations between a considerable number of sugars, gives a very strong experimental basis for this statement. On the other hand, it is well known that such reactions often give racemic mixtures, which indicates that a shifting of groups with regard to a central carbon atom takes place much

more easily than the shifting of a group from one carbon atom to another, at least in saturated compounds. There are also a number of extremely interesting cases where a reaction gives rise to the optical antipode. Thus Walden has shown that *l*-chlorosuccinic acid is converted by silver oxide into *l*-malic acid, while potassium hydroxide converts it into the dextrorotatory acid (*Ber.*, 1899, xxii., 1855). It is evident that in one case or the other there has been a shifting of the groups. Again, Ascham has shown that when *d*-camphoric acid is heated with hydrochloric and acetic acids it may be about half converted into *l*-isocamphoric acid, and that the latter suffers a similar transformation (*Ber.*, xvii., 2004). This case is more complicated, as a "cis" and "trans" isomerism of cyclic compounds is involved, as well as the optical difference. Not many cases of this character are known at present, but such cases certainly deserve further study, and must be reckoned with in considering the question we have before us. Le Bel (*Journ. Chim. Phys.*, 1904, ii., 344) has already pointed out the theoretical significance of Waldron's work.

While we may feel that we have comparatively sure ground in the application of the theory of van't Hoff and Le Bel to optically active and to cyclic compounds, the case is quite different when we come to the consideration of what are commonly known as "double" and "triple" unions. Professor Michael has done a very great service to chemistry in showing that the supposition of a more or less definite tetrahedral shape for the carbon atom and of "favoured" configurations often lead to conclusions which are at variance with the facts. Philips (*Am. Chem. Journ.*, xxiv., 428) and Blanchard (*Ibid.*, xxvi., 281; xxvii., 428) and myself have found a case in which the addition of hydrobromic acid to an unsaturated compound produces an optically active body, which evidently has the same configuration as the amino and hydroxy acids from which the unsaturated body is formed by the loss of ammonia or of water. We have here, apparently, a potential asymmetry occasioned by the double union which it is difficult to reconcile with the prevailing conception of such unions. This case is complicated by the presence of a second asymmetric carbon atom in the molecule and is worthy of further study. Rabe and Billmann have recently described a similar case, but very few instances of this kind are known (*Liebigs Ann. d. Chem.*, cccxxiii., 25).

Pfeiffer (*Zeit. Phys. Chem.*, xliii., 40) has recently suggested a new interpretation of van't Hoff's hypothesis as applied to unsaturated compounds. Pfeiffer assumes that unsaturated compounds retain essentially the same configuration as the saturated compounds from which they are derived. On this side his interpretation is closely related to the old theory of free valences, which, if I understand him correctly, is favoured by Professor Michael. Pfeiffer also brings his interpretation into a close relationship to Werner's theory of inorganic metallic compounds. The most serious objection to the theory is that it supposes the existence either of trivalent carbon atoms or of free valences, in ethylene and its derivatives, an objection which has appeared to most chemists very strong in the past. Pfeiffer points out, it is true, that since the discovery of triphenylmethyl we can no longer deny the possible existence of a trivalent carbon atom.

(The fact that triphenylmethyl exists as a doubled molecule in solution should not, I think, lead us to discard the monomolecular formula for a very many more than we consider that acetic acid has, in the ordinary sense of structure, a doubled molecule, because it exists as a doubled molecule in solution in benzene, or in the state of vapour just above its boiling point, nor because it forms acid salts. In these cases the chemical evidence appears to be more important and more conclusive than the physical. It is probable that the doubled physical molecule is the result of forces which do not produce a stable structure in the ordinary sense.)

It would seem, however, that the great difference between the intense chemical activity of triphenylmethyl and the comparative inactivity of ethylene demonstrates that, if the latter does in reality have free valences, the fact that

there are two such valences reduces the activity of each enormously. The inactivity of carbon monoxide may be significant in this connection.

A more serious objection to Pfeiffer's hypothesis lies in the fact that he supposes so slight a difference in the configuration of fumaric and of racemic acids, that it is difficult to see why the former as well as the latter might not be split into a pair of optically active bodies.

(To be continued.)

THE USE OF COMPLEX SALTS IN ELECTROLYTIC ANALYSIS. SEPARATIONS OF COPPER FROM ARSENIC AND ANTIMONY, OF NICKEL FROM ZINC, OF ZINC FROM IRON, &c.

By A. HOLLARD and L. BERTIAUX.

WHEN from a mixture of several metals in saline solution we wish to separate one only of them by means of the electric current, it suffices, when possible, to change the other metals, which should remain in the bath, into the state of complex salts. These metals, which are then no longer in the state of ions, but are contained in the complex ions, can no longer be deposited under the influence of the current. If, for example, we require to change arsenic and iron into the state of complex salts we can form the following compounds:—

$\text{Na}_3(\text{AsO}_4)$, dissociable into the ions $3\text{Na} + \text{AsO}_4$;
Arseniate of sodium.

$\text{K}_4(\text{Cy}_6\text{Fe})$, dissociable into the ions $4\text{K} + \text{Cy}_6\text{Fe}$.
Ferrocyanide of potassium.

The arsenic and the iron in this state cannot be deposited on the cathode; at the most they might be deposited on the

anode in the form of the complex ions AsO_4 and Cy_6Fe .

The use of complex salts for electrolytic separations was recommended some years ago by Freudenberg (*Zeit. Phys. Chem.*, vol. xiii., p. 97), but the method has been very little used, no doubt on account of the difficulty experienced in a mixture of salts, of making some only of them go into the state of complex salts.

We will now describe the manner in which we have used complex salts in electrolytic analysis:—

1. Copper is frequently accompanied by notable quantities of arsenic, both in its ores and in raw copper. The electrolytic estimation of the copper is then rendered impossible, because the arsenic is deposited with the latter portions of the copper; the copper becomes black, and if the amount of arsenic present is in any way large the deposit is spongy, and does not adhere to the cathode. We have succeeded in preventing the deposition of the arsenic on the cathode by making it pass into the form of

the ion AsO_4 , and keeping it in this state. When we electrolyse a nitric solution of copper and arsenic, the

arsenic certainly goes into the state of AsO_4 ions, but under the reducing influence of the current it soon passes into the state of As ions, and is deposited on the cathode.

To maintain the arsenic in the state of AsO_4 ions, it suffices to add ferric sulphate to the bath (a quantity corresponding to 0.1 grm. is quite enough), the copper is then deposited in the pure state. When the copper is accompanied by antimony, we add SO_4Pb before the electrolysis (0.4 grm. is quite sufficient); the peroxide of lead which is then deposited on the anode retains the antimony (see Hollard, *Bull. Soc. Chim.*, 1903, vol. xxix., p. 155).

2. Separation of Nickel from Zinc.—We have already shown that the electrolytic separation of nickel and zinc is

impossible by the ordinary methods of electrolysis on account of the very close values of their tensions of polarisation. Nevertheless, we have already pointed out a means of effecting this separation; it consists in preventing the disengagement of oxygen at the anode by making use of a soluble anode (Hollard, *Bull. Soc. Chim.*, 1903, vol. xxix., p. 116), or by the addition of a suitable reducing agent (Hollard and Bertiaux, *Bull. Soc. Chim.*, 1904, vol. xxxi., p. 102); the resistance of the bath is then sufficiently reduced for the separation to take place. We will now describe a new method for this separation. It consists in changing the zinc to the state of a complex nitrite of zinc and ammonium. We have made quite certain that this salt does not give any deposit of zinc by

electrolysis; thus there are no Zn^{++} ions formed in solution; this is, consequently, a complex salt to which we can give the provisional formula $2NO_2Am_4(NO_2)_2Zn = Am_2[(NO_2)_4Zn]$, a complex nitrite of zinc and ammonium, dissociable into ions of $2Am$ and $(NO_2)_4Zn$. The method of operating is as follows:—

The nickel and zinc in the form of sulphates are treated successively with 5 grms. of sulphate of magnesia, 25 c.c. of ammonia at $22^\circ B$, dilute sulphuric acid until the bath is slightly acid, 12.5 grms. of nitrate of ammonia, and, finally, with at least 25 c.c. of a saturated solution of sulphurous acid. Boil until the odour of sulphurous acid has disappeared, dilute with water, and add 25 c.c. of ammonia at $22^\circ B$.

The solution, diluted to 300 c.c., is submitted to a current of 1 ampère at a temperature of about 85° . The electrodes have been described already (Hollard, *Bull. Soc. Chim.*, 1903, vol. xxix., p. 1074). The nickel is deposited in a few hours at the most.

Results of Experiments.

Amount taken.		Ni deposited.
Zn.	Ni.	
0.2552	0.2500	0.2547
0.2552	1.0000	0.2530
0.2552	0.0000	0.2536
0.2552	0.2500	0.2544
0.2552	1.0000	0.2547

3. We have found another manner of applying complex salts to the separation of zinc and iron by changing the latter to the form of ferrocyanide. The solution of the metals in the form of sulphates is treated with a large excess of a saturated solution of SO_2 , and then heated; this reduces the iron. When the solution is decolourised the heating is still continued to drive off the excess of SO_2 . Add carbonate of soda to the very hot solution until an abundant precipitate is formed, then a solution of sulphurous acid until the latter is re-dissolved; finally a mixture of 30 c.c. of cyanide of potassium at 20 per cent, and 50 c.c. of soda at $15^\circ B$. In this manner the iron passes into the state of ferrocyanide. Dilute to 300 c.c., and electrolyse in the cold with a current of 0.4 ampère, with a cathode previously covered with copper. The zinc deposited may contain 1 or 2 milligrms. of iron (see below) which can be estimated by means of permanganate of potash. The presence of aluminium does not interfere provided there is not more than 0.5 gm. present.

4. We have also used complex salts for the separation of tin and antimony from copper. We have already described this method, in the year 1900, in a paper on the "Analysis of Commercial Copper" (Hollard, *Ann. de Chim. Analytique*, p. 330). We referred to it again in 1903 (Hollard, *Bull. Soc. Chim.*, vol. xxix., p. 262). Our reason for mentioning these dates is that this process has been published under the name of Mr. Arthur Fischer in the *Berichte* (No. 36, July 11, 1903, pp. 2348—2356), and we claim priority.

Classen has shown that antimony and tin in solution in concentrated sulphhydrate of sodium ($d = 1.22$) could be separated easily by the electric current; the antimony alone is deposited on the cathode. The tin remains behind in the bath in a state of complex combination. With this method of Classen's the increasing amount of polysulphides which is formed round the anode during the course of the electrolysis may pass by diffusion as far as the cathode, where it is able to dissolve the deposited antimony. To prevent the formation of polysulphides, Mr. Fischer proposes adding cyanide of potassium to the bath. Now we have used this reagent long before he did and at the dates we have given above. Further, we have shown that cyanide of potassium has the great advantage of preventing the copper, which almost always accompanies antimony, from being deposited with it during the electrolysis. In fact, the copper alone passes into the state of a complex salt. It may appear strange for the copper to accompany the antimony in a solution of hydrosulphate of sodium in which the copper is supposed to be insoluble. But actually, its solubility is very noticeable in concentrated hydrosulphate of sodium ($d = 1.22$), as we have already shown (Hollard, *Comptes Rendus*, 1896, vol. ccxiii., p. 1063; *Ann. de Chimie Analytique*, 1897, p. 242).

According to the formulæ we have given of the complex ions, it would seem that the metal of the complex ion is never able to be deposited on the cathode. However, it can be so deposited in the case of a certain number of complex salts; the potassic cyanides of silver, gold, mercury, and cadmium, for example. This takes place because certain complex ions are themselves partly dissociated. In such a case the metal present in the complex anion may be deposited directly on the cathode as with a simple salt. As a matter of fact, the concentration of the ions of the metal of the complex salt is always very slight, and we know that, according to Nernst's formula,—

$$e = \frac{K}{v} \log \frac{P}{C}$$

that the tension of polarisation e of a salt is inversely to the concentration C of the ions of the metal.

Nevertheless, the complex salts may be of great service in electrolytic analysis, because even when they are dissociated the metal can only be deposited under the influence of a tension of polarisation much higher than the tension of polarisation of the simple salt.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 15.

RADIUM RAYS AND BENZENE DERIVATIVES.

By HUGO KAUFFMANN.

In order to examine thoroughly into the phenomenon of fluorescence the relations between emission and chemical constitution must be understood. The power of emission will be found to be the same in very many substances, whether they fluoresce or not. In the case of fluorescence other definite conditions also exist, as, for example, the power of absorption for ultra-violet rays.

The radium rays seem to me to afford a very suitable form of energy to apply in the study of the power of emission of various substances. This idea of mine has actually been confirmed. By far the greater number of benzene derivatives are excited to luminescence by the radium rays, many of them so strongly that the luminescence is visible,

even at a distance of 10 c.m. from the radium preparation. After the rays have penetrated a sheet of metal. The experiments were so arranged that the substance to be examined was placed on a sheet of copper about 0.07 m.m. thick, and by means of a special appliance this sheet was placed at certain measurable distances over the radium. Five m.grms. of very active radium bromide were used, contained in a rubber capsule.

The organic compounds examined were used in the solid crystalline state.* Very small quantities of impurities seem to produce a great effect. Thus, for example, of two specimens of hydroquinone di-methyl ether, one of which was quite pure, and the other only slightly adulterated, only the former showed strong power of luminescence. After the second specimen had been distilled no difference could be detected between the two.

The benzene derivatives having many rings show the greatest power of luminescence, and specially those whose vapours give a violet luminescence under the influence of the Tesla currents, i.e., those whose benzene rings are in the X or D condition. Such compounds as appear luminescent at a distance of 12 c.m. from the radium to an eye thoroughly accustomed to the darkness I call very strongly luminous under the influence of the radium rays. Such compounds are, for example, phenanthrene, retene, anthracene, β - β -dinaphthylamine, di-tolylimide, di-phenyl-indol, β , β -dimethoxystilbene. The following luminesces more feebly (in some cases much more feebly):—Phenyl- β -naphthylamine, α - and β -naphthylamine, carbazole, β -anisidine, β -dinaphthyl ether, acenaphthene, naphthalene.

Benzene derivatives whose vapours do not luminesce in the Tesla experiments are in some cases excited very strongly by the radium rays, and in many cases not at all. β -Dibromobenzene and m -dinitrobenzene luminesce only at a distance of some millimetres from the radium. Azobenzene shows no effect in an experiment arranged as above.

Coloured benzene derivatives are apparently very little affected by radium rays, e.g., azobenzene, the nitranilines, diphenylamine quinoxaline, and α -amino-cinnamic acid. These two last compounds are specially noteworthy, for they fluoresce, and it might be supposed that fluorescence is directly connected with susceptibility to the influence of radium rays. But this is not the case, or at any rate there is no direct connection, for these two last compounds only luminesce at a distance of about 2.1 c.m.

The parallelism between the luminescence excited by Tesla currents and that caused by radium rays is obviously fairly far-reaching. If it were thoroughly established we could base upon it a simple convenient method of determining and measuring the X or D condition of the ring system of a solid benzene derivative.

By studying dihydrocollidine-dicarboxylic acid diethyl ester we are enabled to form a tolerably definite opinion as to what part of the benzene ring is responsible for the observed emission. This compound possesses an enormous power of luminescence, far exceeding that of any organic compound yet investigated, and in this respect may be compared with the platinum cyanides. At a distance of 2.5 c.m. it is excited to distinct luminescence by radium rays, which had passed through a zinc plate of 0.75 m.m. thickness. At shorter distances an effect is perceptible, even if the rays have penetrated a layer of three or four such zinc plates.

Screens which are made with this ester can be used for investigating radio-active phenomena almost as well as those of barium platinum cyanide. They have the advantage of being cheaper. (They are, however, not quite so active).

The dihydrocollidine-dicarboxylic acid diethyl ester is just as sensitive as the above dihydrocollidine compound. As these two compounds have only the two parallel double bonds of the six-ring in common with the benzene derivatives in the X condition, which are also excited by radium

rays, it is highly probable that in the case of the substances examined in general the emission of light is conditioned by the presence of these double bonds.

The colour of the emitted light is scarcely recognisable in the case of most substances; in very luminescent colourless substances it is blue to violet; dihydrocollidine dicarboxylic acid diethyl ester gives a very beautiful blue luminescence.

I have also performed experiments to determine which of the radium rays cause the luminescence. It appears that the spots of light projected on substances by radium rays are very easily deflected by an electro-magnet, and thus the β -rays produce the principal effect. Similarly, the Röntgen rays, which closely resemble the γ -rays, frequently had an effect, but always to a slight extent. In the case of these substances which are only capable of being excited at a distance of a few millimetres, the α - and not the β -rays possibly play the principal part.—*Berichte*, 1904, xxxvii., 2946.

RADIO-ACTIVE CINNABARYTES.

By S. M. LOSANITSCH

I HAVE recently examined, for radio-activity, various Serbian ores and other minerals, and have found that native cinnabarytes from two different places (Avala and Bare) has a decided radio-active effect upon the photographic plate. I propose to give here the results of these experiments, with some deductions from them. After I had proved the activity of these Serbian mercury ores, I examined foreign ones also, but then I found that only the ores from Idria (Austria), and especially the variety known as "Ziegeleerz" (brick-ore), are radio-active. Further investigations will perhaps show that many other mercury ores are accompanied by a radio-active element.

To detect the radio-activity, dry silver bromide gelatin plates were used. The powdered specimens contained in a lead vessel with a paper bottom were placed on the plates and left there for three to four days. The plates, when developed and fixed, showed almost equally strong reactions with all these specimens; these reactions were, however, decidedly feebler than those of pitchblende.

The first indications of radio-activity I detected in a cinnabarytes from Avala. But this ore is often permeated with metallic mercury; hence, I considered it necessary to convince myself whether in this experiment the reduction of the photographic plate was not caused by the mercury vapour. Two experiments were sufficient to decide this question; viz., first I showed that pure cinnabarytes crystals are radio-active, and then I convinced myself that metallic mercury under similar circumstances caused no reduction of the photographic plate. Thus the active effect of cinnabarytes is to be ascribed to a radio-active element.

The mercury ores from Avala are often so intimately mixed with barytes that there is no doubt that they have originated contemporaneously. Hence, I thought at first that the barium, as the compound homologous to radium, was the carrier of the radio-activity. But I soon found that the particles of barytes picked out of the mineral are not in the least radio-active. This result led me to the conclusion that the radio-active constituent of cinnabarytes cannot be radium. For if radium were the active constituent of cinnabarytes from Avala, then we could not explain why two elements so closely related as barium and radium, minerals of which have originated contemporaneously in Avala, should have separated from one another from a mixture of the two when the rock was formed. If we further reflect that the radio-active constituent of this cinnabarytes occurs with many other cinnabarytes, then we are led to the assumption that probably the radio-active element of cinnabarytes is allied to mercury, and that therefore it must belong to the Zn—Cd—Hg series of the Periodic System of the elements,

* As far as the experiments show at present no luminescence appears when the substances are in solution.

It may perhaps be a radio-mercury, if I may be allowed to give it a name.

The radio-active constituent of cinnabarites has given equally strong reactions in the case of all specimens examined, which reactions, as I have mentioned before, are much weaker than those of pitchblende. The feeble effect of this radio-active constituent may perhaps be due to the smallness of the amount present. But in my opinion this weak reaction is also a proof that radio-mercury is not identical with radium, but that it is a less strongly active element which belongs to a later less positive homologous series of the Periodic System. As I shall explain later in a theoretical treatise, all these homologous series end with a radio-active element. Moreover, the radio-active elements in the different homologous series differ from one another in the strength of their radiation, according as they belong to the more or less positive homologous series. It is very probable that the radio-active elements in strongly positive homologous series emit stronger radiations than those radio-active elements which belong to the less positive series. According to this supposition it is clear why radium, which belongs to the second strongly positive homologous series, should emit stronger radiation than radio-mercury, which belongs to the ninth, only feebly positive homologous series.

Volatility is known to be a characteristic property of the Zn-Hg series, and thus radio-mercury, if it is a homologue of these elements, ought also to be volatile. This agrees with the fact that the residual portion of roasted cinnabarites shows no radio-activity. Thus roasting the ore has caused the radio-mercury to volatilise with the mercury, which would not be the case if it were identical with radium.

Summary.—By photographic experiments I have shown that certain mercury ores are radio-active, and I have expressed the opinion, based upon certain suppositions, that the radio-active constituent of the mercury ore is a radio-mercury. I hope to confirm this opinion by experiments which I propose to perform very shortly.—*Berichte*, 1904, xxxvii., 2904.

THE DETERMINATION OF MOLYBDENUM IN STEEL AND IN STEEL-MAKING ALLOYS.*

By FREDERICK VAN DYKE CRUSER

and
EDMUND H. MILLER.

(Concluded from p. 207).

PART I. (continued).

Separation of Iron from Molybdenum by Sodium Hydroxide and Precipitation of the Molybdenum as Lead Molybdate. (Brearley, *CHEMICAL NEWS*, 1898, lxxviii., 203; Abs., *Journ. Chem. Soc.*, 1899, lxxvi., 129. Chatard, *CHEMICAL NEWS*, xiv., 175. Brearley, *CHEMICAL NEWS*, 1899, lxxix., 2, and 14; Abs., *Journ. Chem. Soc.*, 1899, lxxvi., 336. Ibbotson and Brearley, *CHEMICAL NEWS*, lxxix., 3; lxxxi., 269).—In order to test the accuracy of the lead molybdate precipitation compared with the titration by potassium permanganate, a series of experiments were undertaken, using the same concentrations of molybdenum and iron as before. The details are as follows:—Two c.c. of hydrochloric acid (sulphuric acid could not be used on account of the subsequent precipitation by lead acetate) were added to each solution, and they were then diluted to from 50 to 60 c.c., 70 c.c. of sodium hydroxide (1:10) were added, and the solution filtered and washed until the filtrate was about 150 c.c. in volume. The precipitate of ferric hydroxide was re-dissolved by hydrochloric acid and re-precipitated as above. The filtrates were combined and boiled down to 200 c.c. An excess of ammonium hydroxide

was added, then 2 to 3 c.c. excess of acetic acid (33 per cent), and 5 to 6 grms. of ammonium chloride. The solution was heated to boiling, 20 to 50 c.c. lead acetate solution (40 grms. per litre of lead acetate) added, depending on the amount of molybdenum present, and the solution stirred vigorously for from two to four minutes, and then treated as under the conditions already given for standardising the molybdate solution.

In measuring the small amounts of molybdenum for the test, 5 c.c. of the standard molybdate solution were diluted to 100 c.c. and the proportional amount used.

Iron taken.	Molybdenum taken.	Lead molybdate found.	Molybdenum found.
Grm.	Grm.	Grm.	Grm.
0.00215	0.04921	0.1920	0.05022
0.00538	0.04921	0.1915	0.05010
0.02690	0.04921	0.1932	0.05054
0.05380	0.04921	0.1927	0.05040
0.10760	0.04921	0.1900	0.04994
0.10760	0.02460	0.0958	0.02306
0.10760	0.00964	0.0403	0.01054

0.10760	0.00197	0.0084	0.00220

From these results we see that the estimation of molybdenum, after the separation of the iron as ferric hydroxide, by titration and by precipitation with lead acetate is about equally accurate. The molybdate precipitation has a slight advantage in accuracy, but as it takes very much longer, the titration method is to be preferred. Two of the precipitates of lead molybdate were dissolved in concentrated hydrochloric acid, diluted with an equal volume of water, and extracted with 50 c.c. of ether; the ether solution drawn off, diluted with water, the ether evaporated off, hydrochloric acid, and then ammonium hydroxide added. The solution was filtered, and the precipitate was dissolved in hydrochloric acid, and the presence of iron shown by potassium thiocyanate. This experiment was made in order to corroborate the theory that ferric molybdate is formed, and is slightly soluble in excess of alkali.

Effect of certain Metals on the various Methods.

In order to test the different methods when the metals commonly added are present, and also those which in future may be added, experiments were made with mixtures of the molybdenum and iron solutions, adding vanadium, tungsten, uranium, and chromium.

Separation of Iron by Sodium Hydroxide and Titration of the Molybdenum by Potassium Permanganate.—In making the following experiments, the operation was conducted under exactly the same conditions as used for the estimation of molybdenum, separating the iron by sodium hydroxide and titrating the reduced molybdenum by potassium permanganate, with the exception that the iron was not re-precipitated. The relative amounts of iron and molybdenum taken were those corresponding to the usual molybdenum steel. This relation was kept constant, and the amount of other metals varied.

0.1076	0.00492	0.00716	0.00242
0.1076	0.00492	0.01074	0.01210
0.1076	0.00492	0.00545	0.00190
0.1076	0.00492	0.00749	0.00951
0.1076	0.00492	0.00560	0.00210
0.1076	0.00492	0.00560	0.01048

The vanadium added was pure V_2O_5 (containing 56.22 per cent of vanadium). The uranium salt was uranium nitrate, C. P., Kahlbaum (containing 47.57 per cent

* Read at the meeting of the New York Section of the American Chemical Society, January 8, 1904. From the *Journal of the American Chemical Society*, xxvi., No. 6.

uranium). The tungsten was added in the form of sodium tungstate. The amount of tungsten in the salt was determined by converting the sodium tungstate into tungsten trioxide, and weighing the ignited tungstic oxide in a porcelain Gooch crucible. The amount of tungsten present in the salt was found to be 60.49 per cent. The chromium was added as sulphate, obtained from pure chromic acid.

From the results obtained we see that vanadium, tungsten, and uranium all interfere with the method, chromium giving slightly higher results than those obtained where iron only is present.

The vanadium goes partly into solution, some being precipitated as a ferric vanadate with the iron, as shown by Pope ("Investigations of Magnetic Iron Ores from Eastern Ontario," *Trans. A. I. M. E.*, October, 1899, xxix., 372), and thus gives high results, being reduced with the molybdenum, and oxidised by the potassium permanganate during the titration of the molybdenum.

The uranium probably forms a uranyl molybdate, which is soluble in excess of alkali, and this is reduced to UO_2 and oxidised again to UO_3 , and gives high results. The filtrates from the ferric hydroxide, after adding sodium hydroxide, were yellow in colour.

Tungstates and tungstic acid are soluble in alkali, and, of course, are present with the molybdenum in the filtrate.

Separation of Molybdenum from Iron as Molybdenum Trisulphide by Hydrogen Sulphide under Pressure, and Titration with Potassium Permanganate.—In order to determine the effect of these metals upon the precipitation method by hydrogen sulphide under pressure, a series of experiments similar to the last were conducted. The experiments were pursued under the same conditions as for the determination of molybdenum in the absence of these metals, and the results obtained showed that neither vanadium, tungsten, uranium, or chromium interfered, even when the quantities were increased. In the case of tungsten 3 to 4 grms. of tartaric acid were added in order to keep the tungsten in solution, as in the method for the separation of tungsten from molybdenum by H. Rose (Treadwell, "Kurztes Lehrbuch der Analytischen Chemie," 1902, vol. ii., p. 187).

PART II.

A new method for the determination of molybdenum in steel and steel-making alloys was then devised, founded upon the foregoing results, and then tested by the analysis of a set of samples of molybdenum steels and alloys, and compared with a typical sodium hydroxide separation method, followed by titration with potassium permanganate, and the precipitation method as lead molybdate.

After considerable experimenting the following method was used for analysis:—

For Molybdenum Steel:—Dissolve about 1 gm. of drillings in 80 c.c. of "silicon mixture"—500 c.c. concentrated nitric acid, 150 c.c. concentrated sulphuric acid,

and 1500 c.c. of water (Phillips, "Methods of Iron Analysis, p. 116)—in a porcelain casserole, adding a little at first, as the action is violent. Evaporate to fumes of sulphur trioxide. Allow to cool, and add 50 c.c. of hot water, and heat to boiling in order to get the salts into solution. Pour the solution into a pressure bottle, and add 6 c.c. concentrated sulphuric acid. Dilute until the bulk of the solution is about 200 c.c., and pass a very rapid stream of hydrogen sulphide through the solution until the precipitate collects. Then close the bottle, and heat in a water-bath at 100° C. for from one to two hours. Allow to cool, empty the contents into a beaker, and wash out the bottle. Filter on a Gooch crucible, using suction, and wash with dilute sulphuric acid (1:50) saturated with hydrogen sulphide. Remove the precipitate and asbestos with a glass rod, and place in a small casserole, washing out the Gooch crucible with water. Add 10 c.c. concentrated hydrochloric acid, 5 c.c. concentrated nitric acid, and 10 c.c. concentrated sulphuric acid, and evaporate to very copious fumes of sulphur trioxide, blowing air through the solution. Allow to cool, add 50 c.c. of water, then ammonia in excess, and filter out the asbestos, and a little ferric hydroxide. Wash thoroughly with hot water. The filtrate is then acidified, run through a reductor, and titrated with potassium permanganate, using the same conditions as for standardising the permanganate solution.

For Ferro-molybdenum.—Dissolve 4 to 5 grms. of ferro-molybdenum in 180 to 200 c.c. "silicon mixture," pour the solution into a standard litre flask, and dilute to the mark when cold. Take out portions of 50 c.c. or 100 c.c., and evaporate to fumes of sulphur trioxide, and proceed as in the case of molybdenum steel.

For Molybdenum Metal.—Dissolve 2 to 3 grms. of metal in "silicon mixture," add concentrated hydrochloric acid, and heat for some time. Dilute with water, and filter into a litre flask. Burn the filter, moistened with nitric acid in a platinum crucible, using as low a heat as possible, and fuse the residue with potassium pyrosulphate. Dissolve the melt in hot water, and add it to the solution in the flask. Allow to cool, and dilute to the mark. Take out portions of 50 c.c., and proceed as in the case of molybdenum steel.

Tungsten, if present, separates out partially as tungstic oxide when the solution is evaporated to fumes of sulphur trioxide. This may be tested for by dissolving it in ammonia, making strongly acid with hydrochloric acid, adding a saturated hydrochloric acid solution of stannous chloride, and then ammonium or potassium thiocyanate. A deep green colour shows tungsten. Molybdenum, under similar conditions, gives a deep red colour.

It is very important to note that tungsten trioxide is quite soluble in acids, although otherwise stated by most authorities (Corney's "Dictionary of Solubilities," p. 438; Storer's "Dictionary of Solubilities"; Watts's "Dictionary of Chemistry."

When tungsten is present, after dissolving the steel in the "silicon mixture," and evaporating to fumes of sulphuric trioxide, allow to cool, add 50 c.c. hot water, 5 grms. of tartaric acid, and heat to boiling. Filter into the pressure bottle, and wash the residue with hot water. Then wash the residue back into the casserole, and repeat the treatment with "silicon mixture" and tartaric acid as before. Filter again into the pressure bottle, and when washed proceed as already described.

"Silicon mixture" was found to be the best solvent for molybdenum steels and ferro-molybdenums, and was also used because it is a common reagent at the steel works. When tungsten was present it was found necessary to re-treat the residue, as it contains a little molybdenum.

In titrating with potassium permanganate, the conditions used were those given by Miller and Frank (*Journ. Am. Chem. Soc.*, 1903, xxv., 919). Length of column of unamalgamated zinc (20 to 30 mesh), 15 inches; time of passage, six minutes; temperature, 70–75° C.; volume of solution, 200 to 250 c.c.; acidity, 10 c.c. concentrated sulphuric acid; and titrated immediately. The following

percentages of molybdenum were obtained by these methods:—

Molybdenum steel	3.63	3.62	3.595	—
Molybdenum-chromium steel ..	4.02	4.11	4.09	—
Molybdenum-vanadium steel ..	9.11	9.12	9.26	—
Molybdenum - chromium - tungsten steel	3.47	3.51	—	—
Ferro-molybdenum	44.50	44.57	44.72	—
Ferro-molybdenum, high in sulphur	34.18	34.24	34.42	34.49
Molybdenum metal	83.84	84.00	84.00	84.16

In analysing the molybdenum-chromium-tungsten steel the residue was not filtered out at first, and the results obtained for percentages of molybdenum were 4.06 per cent, 4.04 per cent, and 3.97 per cent, due to small amounts of tungsten which were dissolved by the acids when making the final evaporation with sulphuric acid. The solution was filtered and washed before the addition of ammonia.

In order to compare this method with those now in general use, the same samples were next analysed by the latest modification (*Iron Age*, Nov. 20, 1902; *Journ. Am. Chem. Soc.*, 1903, xxv., 215) of the method of Kopp, Brakes, and Auchy, which is in brief as follows:—Dissolve 0.8 gm. of drillings in a mixture of 15 c.c. dilute nitric acid, 10 c.c. concentrated hydrochloric acid, and 3 c.c. concentrated sulphuric acid. Keep covered. Evaporate to fumes, which must be very dense, being careful that no nitric acid remains on the cover. Boil the residue with 50 c.c. water. Allow to cool, and pour by degrees with shaking into 100 c.c. of caustic soda solution (1 pound of caustic soda in 2000 to 2100 c.c. water). Dilute up to 200 c.c. (by 200 c.c. graduated Erlenmeyer flask), mix well by shaking, and allow to settle. Filter through a dry filter into a 100 c.c. measuring flask, till mark is reached, add 15 c.c. of concentrated sulphuric acid, reduce, and titrate.

The percentages of molybdenum obtained were as follows:—

Molybdenum steel	3.91	3.92	4.08
Molybdenum-chromium steel ..	4.28	4.37	4.43
Molybdenum-vanadium steel ..	11.72	11.63	11.96
Molybdenum-chromium-tungsten steel ..	6.21	6.26	6.30
Ferro-molybdenum	46.78	46.93	47.01
Ferro-molybdenum, high in sulphur ..	36.21	36.26	36.32
Molybdenum metal	86.58	86.58	86.88

In reducing and titrating the molybdenum in the foregoing samples, the conditions just described for reducing and titrating were followed.

From the results we see that when molybdenum, or molybdenum and chromium, are present, the results are high, due to the formation of a ferric molybdate, which is slightly soluble in the large excess of alkali. The method has the advantage of being very rapid. Three c.c. of concentrated sulphuric acid is too small an amount when evaporated to fumes of sulphur trioxide in order to get rid of all other acids. Eight to 10 c.c. are preferable. A defect in the method is the addition of 15 c.c. of concentrated sulphuric acid to the alkaline filtrate, containing molybdenum for reduction and titration. No correct results can be obtained in reducing and titrating molybdenum, unless the same conditions are followed in analysing the steel as are used for standardising the permanganate solution. The amount of free acid should be kept constant. The solution should be made neutral, and then a definite quantity of concentrated sulphuric acid added in excess.

If tungsten, vanadium, or uranium be present, the method is worthless, as they will be obtained in the filtrate with the molybdenum, and will be reduced and re-oxidised by the permanganate.

The next method used was that of Ibbotson and Brearley, as given in their "Analysis of Steel Works Materials," p. 84, slightly modified to obtain more correct results, by statements made previously by them in the *CHEMICAL NEWS*, (1900, lxxxi., 269), i.e., re-precipitating the lead molybdate to get rid of silica and any other impurity. The method used was as follows:—

Dissolve 2 grms. of the sample in hydrochloric acid and oxidise by nitric acid or potassium chlorate. Add sodium carbonate, taking care to stop the addition short of the production of a red colour or precipitate. Pass through a small pulp filter, and place the filter in a flask containing 30 to 40 c.c. more of double normal caustic soda than is necessary to precipitate the whole of the iron.

After disintegrating the added filter, which may possibly contain a little tungstic or molybdic oxide, heat the contents of the flask to boiling, and add the hot solution, shaking constantly. Make up to 500 c.c., filter off 250 c.c., add a drop of methyl orange, and a decided excess of hydrochloric acid, then an excess of lead acetate solution (40 grms. of crystallised lead acetate per litre), and more than enough ammonium acetate to destroy the free hydrochloric acid. Heat the solution to boiling, allow to settle, filter, wash with hot water, ignite, and weigh the lead molybdate.

In carrying out this method, difficulty was first encountered in dissolving the steels, as hydrochloric and nitric acids are not the best solvent for a molybdenum steel, and in the case of the samples of ferro-molybdenum it was found impossible to get them into solution completely by the use of hydrochloric and nitric acids. In adding sodium carbonate, it is difficult to get the solution at the right point of acidity. If left too acid, there will not be enough sodium hydroxide to separate the iron and the molybdenum, as only a small excess is used.

Great difficulty was encountered at this point, on account of the reddish colour of the steel solution. By increasing the strength or amount of sodium hydroxide added, this could be remedied. This would also obviate the necessity of filtering the solution of the steel, and treating the residue separately.

In precipitating the molybdenum as lead molybdate, a decided excess of hydrochloric acid is first added, and then this excess of hydrochloric acid is destroyed by the addition of ammonium acetate. If there is a large excess of hydrochloric acid present, there will be a large excess of acetic acid present, and this affects the precipitation of lead molybdate (Brearley, *CHEMICAL NEWS*, 1893, lxxviii., 203). By first neutralising the acid with ammonia, and then adding 2 to 3 c.c. of acetic acid (33 per cent) in excess, the best conditions for precipitation are obtained.

In analysing the molybdenum-chromium-tungsten steel, the following modification of the method was used (Ibbotson and Brearley's "Analysis of Steel Works Materials," p. 85):—Dissolve the ignited lead salts in hydrochloric acid, add a few drops of nitric acid, and evaporate nearly to dryness. Add 100 to 200 c.c. of dilute hydrochloric acid (1:4), boil, and filter off the tungstic oxide. The molybdenum is re-precipitated from the filtrate with lead acetate, &c.

It is claimed that an accurate separation of the two oxides from their lead salts can be made in this manner, no matter in what proportion they exist. The percentage results obtained were as follows:—

Molybdenum steel	3.84	3.68	—
Molybdenum-chromium-tungsten steel ..	4.31	4.43	4.44

The precipitates of ferric hydroxide from the molybdenum steel were dissolved in acid after thorough washing, and the iron precipitated again by a large excess of sodium hydroxide (200 c.c. of 54 normal sodium hydroxide), and the filtrates precipitated with lead acetate as before. The results were 3.93 and 3.90 per cent of molybdenum, showing that the molybdenum had not been completely separated from the iron.

In analysing the molybdenum-chromium-tungsten steel, the results are about 0.9 per cent high, due to tungsten, as tungstic acid is not precipitated completely by boiling to a small volume with acid.

The results obtained on the molybdenum-chromium steel were very low, the molybdenum not being completely separated by the small amount of alkali used.

Vanadium interferes with the lead molybdate precipitation, as stated by Ibbotson and Brearley.

9. The sulphide precipitation, followed by reduction and titration with potassium permanganate, not only gives accurate results, but has the great advantage that nothing which is present in steels, ferro-molybdenum, or molybdenum metal, interferes with the accuracy of the results.

When rosaniline trichlorhydrate is dissolved in mineral acids, there is a secondary phenomenon, lasting for eight minutes, in which the liquid loses its red colour and heat is evolved. The reaction takes place in an inverse sense, an equivalent quantity of heat being absorbed when rosaniline carbinol is dissolved in acetic acid. The colourless compounds were formerly thought to be carbinol salts, $(\text{HCINH}_2\text{C}_6\text{H}_4)_3\text{COH}$. Further work has, however, convinced the author that the colourless compounds are the new cyclohexane salts. He thus arrives at the following conclusions:—1. The fuchsines, treated with excess of mineral acid, take up 4 molecules of water; the quinone nucleus is transformed into the hexahydrobenzene nucleus, and colourless solutions of tetraoxycyclohexanerosaniline trichlorhydrate are formed. 2. In the neutralisation of the rosaniline carbinols by an acid, the benzene nucleus always first passes into the hexahydrobenzene nucleus before finally being transformed into the quinone nucleus.

New Work.—Prof. Raphael Meldola is to be congratulated on the completion of Volume I. of "The Chemical Synthesis of Vital Products and the Interrelations between Organic Compounds," upon which he has been engaged since 1895, and which is to be published by Mr. Edward Arnold on November 1st. This important work, containing, as it does, in the most accessible form, the net results of modern research in the department of synthetical chemistry up to the moment of going to press, will be of the utmost value to investigators in this field both at home and abroad.

MEETINGS FOR THE WEEK.

WEDNESDAY, Nov. 2nd.—Society of Public Analysts, 8. "Detection and Estimation of Small Quantities of Maltose in the presence of Dextrose," by J. L. Baker and W. D. Dick. "Use of Palladium-hydrogen as a Reducing Agent in Quantitative Analysis," by A. C. Chapman. "Some Recent Abnormal Milk Results," by S. Harvey.

THURSDAY, 3rd.—Chemical, 8. "Note on the Action of Nitric Acid on the Ethers" by J. B. Cohen and J. Gatecliff. "Condensation of Formaldehyde with Acetone," by E. A. Werner. "Union of Hydrogen and Chlorine—Rate of Decay of Activity of Chlorine," by J. W. Mellor. "Action of Phthalic Anhydride on α -Naphthyl-magnesium Bromide," by S. S. Pickles and C. Weizmann. "Constitution of Nitrogen Iodide," by O. Sikerrad. "Available Plant Food in Soils," by H. Ingle. "Combustion of Ethylene," by W. A. Bone and R. V. Wheeler. "Decomposition of Methylurea," by C. E. Fawcitt. "Influence of certain Salts and Organic Bodies on the Oxidation of Glucose," by Miss E. G. Wilcock. "Influence of Potassium Persulphate on the Estimation of Hydrogen Peroxide," by J. A. N. Friend. "Dynamic Isomerism of α - and β -Crotic Acids," by R. S. Morrell and E. K. Hanson. "Influence of Sunlight on the Dissolving of Gold in an Aqueous Solution of Potassium Cyanide," by W. A. Caldecott. "Fractional Hydrolysis of Amygdalinal Acid" and "Isoamylglycoline," by H. D. Dakin.

UNIVERSITY OF BIRMINGHAM.

ASSISTANT LECTURER AND DEMONSTRATOR IN
CHEMISTRY.

The Council invites applications for this
Appointment.

The stipend will be £750 per annum.

The Candidate selected will be required to enter on his duties at the earliest possible date. Further particulars may be obtained from the undersigned, to whom applications, accompanied by testimonials, should be sent not later than November 7th, 1904.

GEO. H. MORLEY, Secretary

UNIVERSITY OF GLASGOW.

ADDITIONAL EXAMINERSHIPS.

The University Court of the University of Glasgow will shortly proceed to appoint the following additional Examiners:—

(a) For Degrees in Arts and Science.—One Examiner in MATHEMATICS. Annual salary, £70.

(b) For Degrees in Arts, Science, and Medicine.—One Examiner in NATURAL PHILOSOPHY (including PRACTICAL PHYSICS). Annual salary, £70. Candidates should be qualified both on the Mathematical and Experimental side. One Examiner in CHEMISTRY. Annual salary, £50.

The appointments will be for three or four years from January 1st, 1905, and, in addition to the above-mentioned salaries, hotel and travelling expenses will be paid.

Candidates should lodge twenty copies of their application and testimonials with the undersigned on or before November 12th, 1904.

ALAN E. CLAPPERTON,
Secretary, Glasgow University Court,
91, West Regent St., Glasgow.

INSTITUTE OF CHEMISTRY
OF GREAT BRITAIN AND IRELAND.

Incorporated by Royal Charter.

NOTICE IS HEREBY GIVEN that the next INTERMEDIATE EXAMINATION will be held at the Laboratories of the Institute, commencing on TUESDAY, the 3rd of JANUARY, 1905.

Examinations in the following branches of the FINAL EXAMINATION for the ASSOCIATESHIP (A.I.C.) will be held in the Laboratories of the Institute, commencing on either TUESDAY, the 3rd, or TUESDAY, the 10th of JANUARY, 1905:—(a) Mineral Chemistry; (b) Metallurgical Chemistry; (c) Physical Chemistry; (d) Organic Chemistry. A Final Examination in Branch (e) The Analysis of Food and Drugs and of Water, including an Examination in Therapeutics, Pharmacology, and Microscopy, will be held in the Laboratories of the Institute, commencing on MONDAY, the 9th day of JANUARY, 1905.

The Examinations are open only to Candidates who have complied with the Regulations.*

Applications for admission to the above Examinations should be forwarded to the Registrar not later than THURSDAY, the 1st of DECEMBER, 1904, on which day the List of Candidates will be closed. (By Order of the Council)

RICHARD B. PILCHER,
30, Bloomsbury Square, London, W.C., Registrar and Secretary.

VOL. XC., No. 2345.

NOTE ON THE HIGHER GLYCERIDES.*

By J. B. HANNAY, F.R.S.E., F.I.C.

It has long been known that oxide of lead can be dissolved by heat in linseed oil, as it has been so employed to improve the "drying" qualities of the oil. Some qualitative experiments conducted in the year 1895 showed me that this power of dissolving oxide of lead was common to all the higher glycerides, and also that they took up a fixed quantity and formed, not mere solutions, but true chemical compounds. As the compound yielded a lead soap and glycerin on treating its ethereal solution with water in the cold, it seemed to offer a means of throwing further light on the course of saponification of the glycerides.

It was found that on heating tristearin, triolein, trilinolein, and triricinolein, as represented by purified stearin, olive oil, linseed oil, and castor oil, as also rape, cotton-seed, and earth-nut oils, with dry litharge in fine powder, at a temperature of from 165° to 180°, combination took place, the oxide of lead being gradually dissolved and the liquid becoming more and more viscid until, after two hours' heating, rising to a temperature of 180° to 190°, saturation seemed to be attained, and the result was a wax-like body, viscid when hot, and which, on cooling, formed a brittle solid like Carnauba wax, and which did not adhere to glass.

The compounds formed (except that formed from stearin, which is less soluble) were very soluble in liquid paraffins and olefines, and many hydrocarbons, such as benzole, toluol, xylol, and also in carbon tetrachloride and disulphide, chloroform, amyl acetate, and glacial acetic acid, but practically insoluble in alcohol and acetone.

By washing with acetone, or precipitating the compound from its chloroform solution by acetone or alcohol, the new compounds may be freed from uncombined oils. The solubility of both the oleic and linoleic compounds is so great that most of the solutions show no saturation-point, but the solid and solvent are miscible in all proportions.

An analysis of the products, separated from free litharge and oil by solution in chloroform, filtration, and precipitation by acetone, gave metallic lead to the extent of from 36 per cent in the rape oil compound to 41 per cent in the case of the linseed oil compound; other oils yielding compounds between those limits. This gives three atoms of lead to each molecule of triglyceride, or a formula of—

where $\bar{\text{F}}$ represents the radicle of one of the fatty acids.

Evidently, then, the lead was in some relation to the acid radicle, but as the acid had the hydrogen of its carboxyl removed by combination with the glyceryl radicle, the combination must be quite other than the formation of a salt of the acid, as in "saponification."

An examination of the reaction for the evolution of water was made by mixing 20 grms. of dried olive oil with 25 grms. of litharge which had been heated to 250°. These were combined at 180°, and a slow current of dried carbon dioxide passed over the mixture, and any moisture collected as usual by a tube with pumice saturated with strong sulphuric acid. The loss of weight after combination was 0.235 gm., while the gain in weight in the drying tube was only 0.072, showing that no moisture was evolved, and that the loss of weight was due to small quantities of essential oil, &c., present in the olive oil; so that the reaction was a direct combination of the glyceride with the oxide of lead.

Experiments showed that this combination begins to

take place slowly with stearine at 160°, but cannot be completed at that temperature. With triolein it commences about 130, and with trilinolein as low as 87° there is some action, the chemical activity being thus greater as the glyceride acids are of a less saturated type. Ordinary ground fused litharge did not act as quickly as that produced by carefully dehydrating lead hydrate, which produces a light flocculent litharge, very finely divided, and it was with oxide thus prepared that all the experiments quoted were done.

It was found that the same glycerides acted upon dry lead carbonate when raised to a temperature of 166°, and the same compounds were formed. At this temperature lead carbonate is not decomposed by heat alone, and as the glyceride attacks the carbonate with strong effervescence, it is apparent that we have true chemical action. When an excess of lead carbonate was used, the unchanged carbonate representing the excess was recovered in full by dissolving the compound in ether, chloroform, or petroleum spirit, and filtering.

Experiments were made with the above oils using an excess of lead carbonate, and the carbon dioxide was absorbed and weighed, and a drying tube placed to retain any water; but in no case was any appreciable amount of water given off. These weights were checked by the loss of weight of the flask and contents, and were found to agree fairly well.

Two typical experiments may be quoted—one with olive oil and the other with linseed—triolein and trilinolein:—

Oleic taken		20.703 grms.
Lead carbonate		36.276 "

Theory for
olein + 3PbO.

Carbon dioxide collected		3.127	3.051
Collected in H ₂ SO ₄ tube (trace H ₂ O)		0.014	0.000
Total loss of weight		3.155	3.091
Carbonate of lead recovered		17.392	17.578
Weight of compound formed		36.675	36.350

The oils were dried by heating to 105°, and the carbonate of lead to 100°, while in the experiments with litharge the latter was heated to about 300°.

In the case of the linolein experiment and several other oils, the result was checked by dissolving the compound in ether, shaking with water, and separating; the operation being repeated several times to extract all the glycerin. It was found to be difficult to obtain the last traces of glycerin in this way, so the lead salt was generally decomposed by sulphuric acid, and the excess of acid removed by barium carbonate, and the glycerin estimated. The following is a typical result:—

Theory for
3PbO.

Linolein taken		8.705	—
Carbonate of lead dissolved		7.890	7.938
Carbon dioxide collected		1.221	1.308
Water and volatile matter		0.012	0.000
Total solid was obtained		14.92	15.337
Glycerin		0.84	0.912
Basic linoleate of lead		14.39	14.693

It was found that if the heating were long continued and carried up to about 200°, it was possible to obtain a lead compound with 2 to 3 per cent excess of lead, but in these cases the compound was very dark in colour, and the action had been pushed too far.

When heated to 180° and kept till saturated, say, for two hours, and extracted with benzene, chloroform, or other anhydrous solvent, the compound had a perfectly constant composition, as shown by the subjoined analyses.

The method of estimating the lead was that of incinerating in a porcelain crucible and burning off any free carbon, then passing hydrogen through a pipe in the cover to reduce any oxide of lead, and weighing the metallic lead. The lead is obtained in this way in bright metallic beads. A portion of the compound was distilled to ascertain if any lead were volatilised during the driving off of the volatile

* The substance of a Paper read before the Chemical Society.

The two hydrogen atoms which replace the lead when water is added and enable the complex molecule to break

up into glycerin and oleic acid, are shown in parenthesis, and the additive compounds formed by bromine, sulphur chloride, or oxygen are also indicated. The compound may be formulated more simply, and the tie formed by the divalent lead shown as—

where 3 of divalent lead replace 6 of hydrogen—3 in the glycerol and 3 in the oleic acid,—thus linking the glyceryl and oleic radicles together. The decomposition by water takes place thus:—

yielding glycerin and a basic oleate of lead.

These two reactions—the combination of the dry oxide of lead with the tri-glyceride and the subsequent decomposition with water—are probably the true steps of the saponification of oils by boiling with litharge and water—the process used in making lead soaps from time immemorial, and by which glycerin was originally manufactured.

(To be continued).

REPORT OF COMMITTEE ON THE
CADIUM CELL.

*To the Board of Directors of the American Institute of
Electrical Engineers.*

THE committee appointed by you to report on the preparation of materials and the construction of the cadmium or Weston cell has made very substantial progress, and begs leave to make the following preliminary report, with the request that the Committee be continued.

The most serious variations in the electromotive force of both Clarke and Weston standard cells have been traced to the influence of the mercurous sulphate. (See *Zeit. für Instrumentenkunde*, February, 1901, and the "Report of the National Physical Laboratory of England" for 1903). The problem of ascertaining the cause of these variations and the development of a standard method of preparing the mercurous sulphate was accordingly taken up by the Chairman of this Committee in conjunction with Dr. George A. Hulett, of the Department of Chemistry in the University of Michigan.

The method of preparation in use by the European manufacturers of mercurous sulphate consists in its precipitation

by bringing together a solution of mercurous nitrate and sodium sulphate or sulphuric acid. This method has been repeated with a number of variations, and the various preparations give variable results when used in the cadmium cell, and all of them higher electromotive force than the mercurous sulphate prepared electrolytically, as described below. These results suggest that perhaps mercurous sulphate might carry isomorphously a small quantity of mercurous nitrate, since both of these salts crystallise in the monoclinic system. In fact, Dr. Hulett has detected the nitrate in commercial preparations, and in some of those made by himself. A cell set up with mercurous sulphate of the standard preparation, to which a trace of mercurous nitrate had been added, showed an increased electromotive force due to the nitrate. Not only does the presence of the nitrate raise the electromotive force of the cell, but the relative amount of the nitrate present appears not to be invariable.

In view of these facts, a new and standard method of making mercurous sulphate from pure mercury and dilute sulphuric acid appeared to be highly desirable. Such a method has been devised by Dr. Hulett; and independently by Dr. Wolff, of the Bureau of Standards. (See paper by Henry S. Carhart and George A. Hulett in the *Transactions of the American Electrochemical Society*, vol. v.; also one by F. A. Wolff, same volume).

A new electrolytic method of preparing the cadmium amalgam, and one for washing the mercurous sulphate to remove the acid without the use of pure water, were also devised. (See specifications below). The results are highly satisfactory, and cells made in accordance with the specifications appended to this report show remarkable agreement and constancy. Your Committee is well satisfied that the principal difficulties in making Weston cells have now been removed.

The two curves in Fig. 1 show the behaviour of two cells for forty days after they were placed in a constant temperature bath, at 21.1°C . Cell D 6 was made with mercurous sulphate prepared in the old way by precipitation; cell D 1 was made with the same materials, except that the electrolytic mercurous sulphate was used. Comment is unnecessary. The electromotive forces given are relative and not absolute.

The accompanying tables exhibit measurements made on cells D 1 to D 4, and F 1 to F 10, all of them set up with the electrolytic mercurous sulphate. The figures were obtained by comparison with an old cell, B 7, by means of a Wolff's potentiometer and a type "H" d'Arsonval galvanometer made by Leeds and Northrup. The fifth decimal place could be read with the greatest ease.

In determining the effect produced by changing a single feature in the preparation of the materials, about 100 cells of the H-form have been made and tested. These are still under observation. All of them, except the first ten, have been hermetically sealed. The sealing is readily effected by making the glass containing cell of a special form, and sealing with two blast lamps.

The Committee offers the following specifications, which are to be considered as provisional only, for the preparation of the cadmium cell with saturated solution and excess of crystals of cadmium sulphate. For the cell so prepared the Committee would suggest the name, "Weston Normal Cell."

1. Mercury.

Mercury free from grease should be first shaken with a nitric acid solution of mercurous nitrate (*Zeit. Phys. Chem.*, xxxiii., 611), and, after drying, it should be distilled in a vacuum at least twice.

2. Cadmium Sulphate Solution.

The best pure commercial salt is dissolved at room temperature in its own weight of distilled water, with the aid of a motor-driven stirrer. The solution must be filtered until perfectly clear; it may then be placed in a large crystallising dish in a small room free of dust; it is of advantage to remove the water vapour by appropriate

drying agents. The slow ensuing crystallisation should yield perfectly transparent crystals. After about two-thirds of the water has evaporated, the mother-liquor is poured off, and only the clear crystals are taken; those that are white are re-dissolved and added to the mother-liquor. The whole is then filtered, and left to crystallise again. The selected clear crystals are rinsed with distilled water, drained, and left to dry.

To make a solution of cadmium sulphate for setting up cells, the pure crystals are put into an Erlenmeyer flask and covered with two-thirds their weight of distilled water. A suitable stirrer (Schultz stirrer, *Ber.*, 1896, 2883) is driven by a motor, for the purpose of causing the water to circulate over the crystals, for at least half a day, preferably in a bath at 25°C ., controlled by a thermostat. The supernatant liquid should be clear, and should remain so indefinitely. It should be left standing over the crystals, and when it is used it should be saturated at a temperature as high as 25°C . The saturation of the solution is of great importance in order that the cells may quickly reach electrical equilibrium.

3. Cadmium Amalgam.

To prepare a 12.5 per cent cadmium amalgam, free from zinc, a large crystallising dish is nearly filled with a saturated solution of cadmium sulphate slightly acidulated with sulphuric acid. In a small low crystallising dish is placed a weighed quantity of pure mercury, and the whole is immersed in the cadmium sulphate solution. The pure cadmium of commerce is melted down into a large button with a stick of cadmium attached for electrical connection; or several of the cadmium rods, bound together, are placed in a vertical position with their lower ends in the solution, and beneath them a small low crystallising dish. If the cadmium disk or button is used, it is placed in the second low crystallising dish, which retains the finely divided dross or powder. The metallic cadmium is then made the anode and the mercury the cathode, connection with the latter being made by means of a platinum-wire sealed, except at its end, in a glass tube. The fall of potential from the anode to the cathode should not exceed 0.3 volt. An ammeter should be used to keep account of the quantity of electricity flowing through the cell, until something more than the necessary weight of cadmium has been deposited on the mercury cathode. The small crystallising dish, containing the cadmium amalgam, and some of the solution, is then removed and warmed over a bath till the amalgam melts under the cadmium sulphate solution. When cool it forms a crystalline disk. This method yields an amalgam free from zinc, and there is no oxide or dross formed, as there is when the amalgam is made by the method of heating. The solid amalgam should next be washed, dried on filter-paper, and weighed. The necessary weight of mercury to make a 12.5 per cent amalgam is finally added. The amalgam should be kept under a pure cadmium sulphate solution, and it must be melted on a water-bath to insure homogeneity before it is used in making a cell.

4. Mercurous Sulphate.

In a flat-bottomed glass vessel or deep crystallising dish place pure re-distilled mercury 2 c.m. or more deep. Cover with dilute sulphuric acid (one of acid to six of water) to a depth of 8 or 10 c.m. Make electrical connection with the mercury as the anode by means of a platinum wire covered, except at its end, by a glass tube. For a cathode use a piece of sheet platinum 50 as to expose to the acid solution a surface of about 50 sq. c.m. A current density of 0.5 ampère per 100 sq. c.m. surface of mercury may be used. A crystalline mercurous sulphate forms soon after the current begins to flow from the mercury to the acid solution. A stirrer, consisting of a glass rod bent at right angles at the bottom, must be used to keep the mercury surface exposed. The foot of the stirrer must pass close to the mercury, and the stirrer must be driven rapidly by a motor to keep the mercury agitated.

A little over 4 grms. an hour can be prepared in this way with a current of half an ampère. The mercurous sulphate formed should be protected from the light, since mercurous sulphate darkened by exposure to light gives too high an electromotive force. The sulphate will be white or grey, according to the amount of finely divided mercury mixed with it. The presence of this mercury in a state of fine division is a distinct advantage. If the stirring is continued after the circuit is broken, the crystals of mercurous sulphate grow in size, become whiter, and subsequent treatment is easier.

The mercurous sulphate may be removed from the mercury by a separatory funnel. It should be kept under the acid solution, one to six, in contact with mercury and in the dark.

3. The Paste.

When ready to fill a cell, the mercurous sulphate, which has been kept in contact with mercury under dilute sulphuric acid, is brought into a Gooch crucible of about 25 c.c. capacity (about three-fourths), avoiding much free mercury, which interferes with the filtering. A tiny filter paper covers the perforations in the bottom of the crucible, and the whole is mounted on a Bunsen filter flask and attached to a filter pump.

The mercurous sulphate is first washed a couple of times with dilute sulphuric acid (15 c.c. concentrated acid to a

without splashing. It should always be wiped with a filter paper or clean cloth before it is introduced into the cell.

The mercury, the thin paste, and the concentrated cadmium sulphate solution may be introduced in the same manner. An alternative method is to fill the cell through little funnels made out of small test-tubes. They must pass through the neck at *a*, and reach well down toward the bottom. After the mercury and the paste have been introduced, both legs of the cell are filled with clean, dry crystals of cadmium sulphate. Enough of the saturated cadmium sulphate solution is finally added to fill the cell to the top of the cross connecting tube.

The sealing off is readily done by means of two small horizontal blast flames, 5 c.m. long, directed in a line toward each other and just meeting. The narrow part at *a* is brought between the impinging flames, the glass quickly softens, and the top part is drawn off. A cell sealed in this way contains nothing but the necessary materials of the voltaic combination. It cannot leak, and can be immersed in a kerosene bath without danger that the oil will penetrate into the inside, as it does with sealing wax and paraffin.

After soldering copper wires to the platinum terminals of the cell, it is desirable to tie them securely with thread to the legs of the cell, as a precaution to avoid the

Fig. 2.

litre of water), and then with the saturated cadmium sulphate solution. The washing with the cadmium sulphate solution should be repeated five or six times to remove all the acid; only a few c.c. of the solution are needed for a single washing; after each washing the cadmium sulphate solution is to be removed as completely as possible by the filter-pump. The last washing leaves the salt ready to be made into a paste. The top layer after the last washing should be rejected.

The paste is then made in a clean agate mortar by grinding together crystals of the pure cadmium sulphate and a little mercury, and then mixing in about three volumes of the mercurous sulphate; finally add enough saturated cadmium sulphate solution to make a thin paste.

6. Construction of the Cell.

The H-form of cell is the most convenient to fill. Fig. 2 shows the glass cell half actual size, ready to be filled. The tubing is drawn out and contracted at *a* so as to leave the diameter about 6 c.m. and with thin walls at this point. The amalgam is melted over a water-bath and is introduced by means of a small tube, slightly contracted at the end, and of a diameter that will allow it to pass freely through the neck *a*. The warmed tube is used as a pipette, and permits the rapid introduction of the amalgam

breaking off of the platinum wire at the point where it enters the glass.

The Committee is indebted to Dr. Hulett for many suggestions in the preparation of these Specifications.

Phosphorus.—R. Schenck.—The black substance resulting from the action of piperidine on solid phosphide of hydrogen has a slightly variable composition (presence of oxygen) when the reacting materials have not been dried with exceptional care. In the latter case we get a certain amount of $P_3H_2 \cdot C_3H_5N$. The ammoniacal salt previously obtained is $P_3H_2 \cdot NH_3$. Ammonia does not blacken P_3H_2 immediately in the cold; the reaction is slow, but it also takes place on heating. In the second portion of his paper the author shows that in the transformation of white phosphorus into the red variety, in the presence of PBr_3 , the reaction is unimolecular and not bimolecular, as has been believed up to the present.—*Berichte*, vol. xxxvi., p. 4202.

PRESENT PROBLEMS OF ORGANIC CHEMISTRY.*

By W. A. NOYES.

(Concluded from p. 215).

WE must admit, then, that we have, at present, no satisfactory theory of double and triple unions, and that we have here a problem which demands a large amount of further work before it is solved. When the solution is reached we shall probably gain a new insight into the perennial question of the structure of benzene, and our knowledge of tautomerism will cease to be, as it is at present, almost purely empirical. It is possible, perhaps probable, that Thiele's "conjugated double unions" will contribute toward the solution.

While I have no comprehensive theory with regard to double unions to advance, I will, with a good deal of hesitation, venture to express some thoughts with regard to the combination of atoms in general which have some bearing on this question. We are all familiar with Faraday's law, that if a current of electricity is passed through a number of cells filled with solutions of different electrolytes, and arranged in series, exactly equivalent amounts of the various components will be liberated at the electrodes in the successive cells. The beautiful experiments of Professor T. W. Richards have demonstrated that we are dealing here with a law which is true for different solvents and over a wide range of temperature; and also that the law is true with a degree of absolute accuracy which is of the same order as the laws of the combination of elements by weight. We are compelled, then, to believe that there is associated with each valence of an ion as it is transported through a solution, or at least as it separates at an electrode, a quantity of electricity which is invariable and independent of the nature of the ion. In other words, we have here a natural electrical unit which can be defined in its relation to atomic weights with a degree of accuracy which seems to be limited only by the refinement of our manipulations.

It is not always recognised as clearly as it should be that this unit quantity of electricity which is associated with one valence of any ion is not a unit of electrical energy. If it were, the same energy would be required to decompose the equivalent quantity of one electrolyte as of every other, which is manifestly not true. While the same current causes the separation of equivalent quantities in the different cells, the differences of potential, and so the amounts of energy required for the separation, vary greatly. It is evident then that when we say that a unit quantity of electricity is associated with each valence of every ion, we do not use the term *quantity* in the sense of quantity of electrical energy. Instead of this, when this conception of a unit quantity of electricity is examined, it will be seen that it is a conception of something whose properties are those of matter rather than those of energy. The facts appear to be consistent with the idea that the unit quantity of electricity of which we are speaking is of a material nature, and you have doubtless already perceived that I have the theory of electrons in mind. The ingenious experiments of J. J. Thompson have given us considerable reason for thinking that the negative electrons are capable of an independent existence, and have also given a probable estimate of their mass, which is small in comparison with the mass of the hydrogen atom.

It has been customary to think of the unit charge of electricity as being involved only in those reactions which occur in solution. If, however, we accept the theory of electrons it is evident that the electrons must be present in the molecule of an electrolyte no matter in what manner it is formed. It is but a step further to the conclusion that the electrons are involved in every combination or separation

of atoms, and, indeed, may be the chief factor in chemical combination.

Professor Kahlenberg has shown that a practically instantaneous reaction takes place between hydrochloric acid and copper oleate in a solution in dry benzene (*Journ. Phys. Chem.*, vi., 1), although the solution does not conduct an electric current, and there is no evidence of the dissociation of either the copper oleate or of the hydrochloric acid. Professor Kahlenberg points out very justly that there is no apparent difference between these reactions and those which take place in aqueous solutions, where we have much independent evidence of the existence of ions. He draws the conclusion that no ions exist in either case. It would seem that we are equally justified in supposing that a substance not already in the form of ions may separate into them under the influence of a second substance with which it can react.

Some time ago Mr. Lyon and myself (*Journ. Am. Chem. Soc.*, xxiii., 460) showed that the primary reaction between chlorine and ammonia gives nitrogen trichloride, nitrogen, and hydrochloric acid, and that these products are formed in such proportion as to lead to the conclusion that three molecules of ammonia react simultaneously with six molecules of chlorine. It was pointed out at the time that the simplest explanation of this result is to be found in supposing that chlorine atoms separate during the reaction into positive and negative ions, while the ammonia separates partly into positive nitrogen and negative hydrogen, and partly into negative nitrogen and positive hydrogen. This was represented graphically thus:—

This hypothesis has met with some approval (Stuglitz, *Journ. Am. Chem. Soc.*, xxiii., 797), but has also received the criticism that such a dissociation as is supposed would result in the spontaneous decomposition of ammonia into nitrogen and hydrogen (*Zeit. Phys. Chem.*, xii., 378). This criticism loses its force if we suppose that the separation into ions takes place only under the immediate influence of the chlorine with which the ammonia reacts. It has been pointed out by many different authors (see Erlenmeyer, jun., *Liebig's Ann. Chem.*, cccxvi., 50) that a separation of atoms from each other must occur either before or at the same time that they enter into combination with other atoms. The only part essentially new in the hypothesis proposed is that this separation is into positive and negative parts, and that the same atom may be sometimes positive and sometimes negative. The idea of a dissociation which occurs under the influence of a reacting substance appears to be implied in a part of Professor Nef's discussion of methylene dissociation, but it is not always clear whether he has in mind chiefly a dissociation of this sort or one which is independent of the interaction of different compounds.

The thought that the same atom may be at one time positive and at another time negative is related to the older electro-chemical theory which supposed water to be positive in acids and negative in bases.

We assume, then, that in every reaction

* Read at the International Congress of Arts and Science in St. Louis, September 21, 1904. From *Science*.

each union involves an attraction between the positive and negative electrons which are associated with the two atoms that unite. In saying this I do not lose sight of the fact that such a thing as attraction *per se* in the sense that one body can influence another at a distance without an intervening medium, is, apparently, inconceivable. I think of the attraction as probably caused by some motion of the electrons which enables them to act on each other through the aid of the ether. It is convenient, however, to speak of this effect as an attraction, since our conception of its real nature is of necessity very vague. One advantage of the idea that the attraction of the electrons is of a kinetic nature is that we may conceive of the same electron as becoming positive or negative according to the nature of its motion.

The common conception at present is that an atom which has lost an electron becomes positive, while either the electron in its independent existence or the atom to which it is attached becomes negative. So far as I am aware, it has not been pointed out that this view leads to the conclusion that the same atom must, under different conditions, have a different weight. Thus a bivalent copper atom which has lost two electrons must weigh less than a univalent copper atom which has lost only a single electron. It is true that our methods of determining atomic weights are scarcely accurate enough to detect differences of this order. The suggestion which is made is that the electrons of two atoms which are united, have motions which correspond to positive and negative charges respectively, and that when the atoms separate these motions may be retained, or lost, as in the case of a mercury atom which is uncombined, or that the motions may be reversed. In accordance with the hypothesis outlined above we must assume that when two atoms separate either one may become positive; dependent partly on their nature, partly on the nature of the reacting substance. The conception here proposed is that of something very similar to the action of the pole of a magnet, which may attract another pole of the opposite kind, or induce the formation of a pole of the opposite kind, or it may reverse the polarity of another magnet.

(This is, of course, only an analogy, and must not be pressed too far; just as the electrical changes of atoms or ions conduct themselves very differently from those of masses. The latter divide themselves between two bodies in contact; the former may be transferred *completely* from one ion to another).

This is, perhaps, simpler than to suppose the transfer of an electron from one atom to another in those cases where the electrical charges of the atoms are reversed in the ionisation. A very accurate determination of the atomic weight of cupric copper as compared with that of cuprous copper might possibly decide between the two hypotheses.

It should be noted that the hypothesis that the electrical charges associated with the atoms are of a kinetic nature, and that these charges may be transferred without gain or loss of matter, is quite independent of the first hypothesis, which is that the atoms are ionised when they separate from each other, and that the same atom may become either positive or negative.

In following farther the thought of the attraction between electrons as the cause of chemical combination, we must suppose that in addition to the effect of this attraction in holding together the atoms which are immediately attached there is a residual effect upon other atoms within the molecule. This gives a rational explanation of the very great difference in the stability of the union between carbon atoms in different compounds, as, for instance, the instability of acetic acid in comparison with butyric acid, occasioned by the substitution of an oxygen atom for two hydrogen atoms of the latter. The study of organic compounds has given us a knowledge of a large number of cases of this sort, and our text-books contain many empirical rules about them, but there have been few, if

any, attempts to give for such facts any rational explanation.

In considering double unions three explanations suggest themselves:—1. We may suppose with Pfeiffer that such unions are in reality single unions and free valences. In this case the presence in adjacent carbon atoms of positive and negative electrons, which are uncombined, would reduce the attraction of each for the electrons of another molecule, thus explaining why two free valences are so much less active than a single one. 2. We may suppose that the carbon atoms are in reality doubly united, but that owing to the localisation of the electrons in definite parts of the carbon atoms, the four electrons involved cannot approach as near to each other as is the case in a single union. This is Baeyer's theory of strain, and is much better in accord than is the theory of free valences, with the fact that cyclopropane and propylene appear to be about equally unsaturated, as evidenced by their heats of combustion and by their conduct toward bromine. On the other hand, it seems to lead logically to conclusions with regard to the addition of bromine to triple unions which Professor Michael has shown are contrary to the facts. 3. Without a condition of strain, we may suppose that the presence of both a positive and negative electron in each of the atoms united by the double union causes a lessening of the attraction of the electrons. This would result in such a union being less stable than a single union. The second and third views appear at present most in accord with the facts—possibly the truth lies in some combination of the two.

Whatever view we may take, it is noteworthy that double unions are usually formed by the loss of a positive and negative atom or group from adjacent carbon atoms, as hydrogen and hydroxyl or hydrogen and bromine. It is also true that in many double unions one of the carbon atoms is more positive than the other, causing the addition of halogen acids in a definite manner which may be predicted in accordance with Michael's "positive negative law." Applying this thought to conjugated double unions we see that of the four atoms involved the two central ones are likely to be positive and negative respectively, and neutralise each other's attraction for outside atoms, while an intensified attraction for outside atoms would be found in the exterior atoms. The effect may be analogous to that of the attractive forces of a magnet which exhibit themselves chiefly at the ends.

But I have permitted myself to wander much further in the field of speculation than was my first intention—further than is at all profitable, I fear, for these questions furnish at present few points for experimental study, and speculations divorced from experiment have usually been profitless. I should be very sorry if what has been said should give encouragement to such speculations. On the other hand, I have a very firm conviction that we should not be content with rounding out organic chemistry as a descriptive science, nor even with adding to the number of empirical rules which enable us to predict certain classes of phenomena. We must, instead, place before ourselves the much higher ideal of gaining a clear insight into the nature of atoms and molecules, and of the forces or motions which are the real reason for the phenomena which we study. When we consider the progress which has been made and the knowledge of structure we now possess, which would have appeared sixty years ago to lie beyond the limits of possible acquirement, it is not presumptuous to think that a more complete knowledge of these questions will at some time be gained. This fuller knowledge will take account, too, of many lines of work upon which I have no time to dwell, such as the question of changing atomic volume to which Professor Richards and Traube have directed our attention, and the knowledge of heats of combustion, of molecular refraction and dispersion, of colour, viscosity, dielectric constants, and other physical properties. The future must give to us a new theory or a development of old ones which shall include all of these phenomena in one comprehensive view.

A RADICALLY NEW METHOD FOR THE DETERMINATION OF SULPHUR IN IRONS AND STEELS.*

By H. B. PULSIFER.

It is with some hesitation one proposes a new method for a determination so long and ably carried on as the determination of sulphur in irons and steels. However, it must be admitted that the two methods at present recognised as giving accurate results, namely the nitric acid method and Bamber's method, are by no means ideal.

These methods are too well known to require description here; Ford and Willey have ably criticised them in a recent article in the *Journal of the American Chemical Society*. The author heartily shares their opinion that for accurate results with the nitric acid method great care is necessary.

Although these methods may be accurate when solution takes place slowly, because of this necessary slowness they lose their commercial value. An ideal method is one which should not lose accuracy when conducted by a skilful but rapid manipulator. Hastening the solution of the iron when dissolved in nitric acid does give low results, while if one resorts to evaporation on a hot plate there is much danger of losing sulphur by bumpings. To devote three-quarters of an hour to the solution alone makes this a very tedious method indeed.

In view of these facts, the author devised and tried the method which will be found below. The time between weighing the sample and precipitating the barium sulphate need not be more than twenty minutes.

Outlined, the process is as follows:—The sample is dissolved in chloric, hydrofluoric, and hydrochloric acids; the residue is then filtered, fused with sodium peroxide, and the fusion dissolved in water and hydrochloric acid. Meanwhile the hydrofluoric acid from the first filtrate has been boiled off, and the two portions are now united and the sulphur precipitated as barium sulphate.

Every step, excepting the boiling off of the hydrofluoric acid, is susceptible of quick and easy manipulation. The solution requires not over two minutes, while the fusion and its dissolving takes less than five minutes. As a matter of fact, several of the results given below took just under twenty minutes between weighing and precipitating.

Hendrixon (*Journ. Am. Chem. Soc.*, xxvi., 747) has shown that iron is quickly and completely dissolved by chloric acid, and that every trace goes to the ferric condition. This also oxidises the sulphur, as the results show. The residue, however, retains some of the sulphur, and its separation from the solution by suction filtration without removing the silica is an endless task, hence the use of hydrofluoric acid. A shorter method for this step would be highly desirable, but even as it is, it is not too tedious, and it unquestionably greatly assists in the rapid solution of the iron, its freeing the iron from silica giving the chloric acid full play on the iron.

The fusion of the residue with sodium peroxide is a very neat and easily performed operation. Once, while putting the sodium peroxide into the crucible on top of the folded moist filter containing the residue—the crucible having just been removed from the flame where it had been drying—sufficient heat remained to ignite the mass, and the whole fusion was completed in five seconds. It is also a pleasure to dissolve and filter a peroxide fusion, as it does not require that patience-trying deliberation needed for the solution and filtration of a sodium carbonate fusion.

The exact details by which the following results were obtained will now be given:—

Two and five-tenths grms. of the sample are placed in a 250 c.c. broad Jena beaker and just fairly moistened with water. The particles inevitably tend to fuse together if chloric acid is put directly on the iron, and the mass is then difficult to get into solution.

Twenty c.c. chloric acid (1·12 sp. gr.) are added and a very little hydrofluoric acid. In fifteen seconds the bubbles are at the top of the beaker, but have never been known to go over. In forty-five seconds the action has subsided, and 5 c.c. of strong hydrochloric acid may be added, the beaker covered with a watch-glass, and any particles on the sides brought down by boiling. It might appear feasible to boil off the excess of hydrofluoric acid at this point, but it was found that this always gave low results.

The filtration is now made by suction, using a 7 c.m. filter. The filter is washed two or three times with as little water as possible and then sucked as dry as may be.

To the filtrate 20 c.c. of strong hydrochloric acid are added, and the whole boiled down over a naked flame, with constant shaking, until the volume is under 10 c.c. and the mass begins to get oily; it is then placed on one side until the portion from the residue is ready to add.

Meanwhile the residue has been placed in a 20 c.c. nickel crucible and covered with sodium peroxide; the cover is then held down by the tongs while a strong flame heats the crucible. The action begins with a little pop and in a few seconds it is over. As soon as the fusion is solid it is cautiously placed in a beaker containing 50 c.c. of water. Hydrochloric acid is added, and in some two minutes all has dissolved, and the few shreds of unburned carbon may be filtered off, while the filtrate goes into the main portion already prepared and waiting.

The whole volume is now about 100 c.c., and is ready for the barium chloride solution.

The sulphur was determined separately in the two portions in the following analyses, so that the amount in the residue might be known.

Treadwell says that the presence of ammonium salts prevents the precipitation of barium fluoride, but this is very questionable indeed, and not confirmed by the author's experiments.

Of course, all the reagents used were tested for sulphuric acid. In portions as large as used for analysis none of them gave even a turbidity with barium chloride. Blanks were also carried through to prove that the hydrofluoric acid had been all removed by boiling as described.

The rapid method referred to is the standard method of solution in strong nitric acid and addition of strong hydrochloric acid when the first action of the nitric acid has ceased. It takes twenty minutes and gives low results.

The very slow method referred to is the same method exactly, except that the solution is made so slowly that at no time do nitric fumes come off rapidly. Solution takes at least thirty minutes, evaporations fifteen more.

Sample No. 3 was a steel in two small pieces, and by all methods took much more time than the samples in the form of drillings.

At the present time chloric acid is a rather expensive chemical for commercial work; however, it will probably be sufficiently cheap if there be much demand for it. Even at its present price it is not too dear, and if the accuracy of the method be sustained it may become the most desirable method after all. The acid with sp. gr. 1.12 is the only one readily obtainable; stronger acids might so reduce the amount of sulphur left in the residue that a fusion would not be necessary, which would greatly add to the desirability of the method.

The method is proposed for routine analysis in all sorts of laboratories, and if it does not come into general use it can at least serve as an independent check method for other methods.

Laboratory of the Henry Soutner Engineering Co.,

Tetraiodide of Zirconium.—A. Stahler and B. Denk.

—The authors heated zirconium, or pure carbide of zirconium, in a current of perfectly pure, dry hydriodic acid gas. Towards 340°, in the first case, and 490°, in the second case, a lively reaction took place, and a reddish sublimate was formed which was found to contain crystals of free iodine. To get rid of this iodine the sublimate was heated in a sealed tube with benzene to 100° with constant agitation. Finally they obtained a reddish-brown crystalline powder, fuming strongly in the air, reacting energetically on water and on the acids, and even with alcohol, forming ZrO_2 and C_2H_5I . It is slightly soluble in C_6H_6 and CS_2 , but more soluble in ether, giving a yellow colouration. The aqueous solution gives, on the careful evaporation of the oxyiodide, $ZrO_2 \cdot 5H_2O$, beautiful, colourless, very hygroscopic crystals, extremely soluble in water or alcohol. They are also obtained by the solution of $Zr(OH)_4$ in an aqueous solution of hydriodic acid. They correspond to the chloride and the oxybromide.—*Berichte*, vol. xxxvii., p. 1135.

PROCEEDINGS OF SOCIETIES.

THE FARADAY SOCIETY.

THE Eighth Ordinary Meeting of the Faraday Society was held on Tuesday, October 25, 1904, in the Library of the Institution of Electrical Engineers. Dr. F. MOLLWO PERKIN, Treasurer, occupied the chair.

Dr. HENRY J. S. SAND read an abstract of his Paper entitled, "The Measurement of the Potential of the Electrode in Stationary Liquids. The Determination of Changes of Concentration at the Cathode during Electrolysis."

The paper was illustrated by lantern views of the apparatus and of the curves embodying the numerical results of the author's experiments.

With a view to determine electrode-potentials in solution, the concentration of which in contact with the electrode should be known as accurately as possible, a method was elaborated for the measurement of potentials of electrodes in stationary liquids free from convection currents.

The apparatus employed was designed so as to allow the electrode to be placed accurately horizontally at the top or at the bottom, according as the electrolyte becomes lighter or heavier during electrolysis. The liquid connection to the normal electrode is tapped off about 3 to 4 m.m. in front of the electrode, the resistance between the junction and the electrode being found either by calculation or else directly by means of a Wheatstone-bridge arrangement for alternating currents, partly composed of condensers instead of resistances.

The method was checked by a series of experiments with a copper-sulphate solution, and gave satisfactory results for the diffusion coefficient of copper sulphate. The electrode-potential of a silver solution showed irregularities which are undergoing further investigation.

When two reactions take place, the method may show their successive occurrence by a sharp break in the potential-time curve, analogous to Nernst and Glaser's breaks ("knickpunkte") in their potential-current curves; the conditions existing at the electrodes are, however, more definitely known than in the "knickpunkt" method. An alcoholic solution of cuprous chloride which had become partially oxidised to cupric chloride showed such a break corresponding to the processes, reduction of cupric chloride and deposition of copper.

When acid solutions of nitrobenzene were electrolysed the time-potential curves showed characteristic retrogressions of potential after a definite time, possibly corresponding to changes in the condition of the cathode.

From experiments on alkaline solutions of nitrobenzene a lower limit for the diffusion coefficient of nitrobenzene in the solutions experimented upon was calculated, and it was shown that Haber's results regarding the dependence of electrode-potential or current-density cannot be explained by concentration changes at the electrode.

Dr. F. M. PERKIN referred to the great practical importance of potential measurements; for example, in oxidation or reduction processes slight differences in the potential often meant very great differences in the amount of energy absorbed.

Prof. THRELFALL said that there was too much uncertainty, due to unknown changes, in complex phenomena, such as had been investigated by the author for the experiments to yield a definite and finite answer. More valuable results might be looked for at the present stage of knowledge if the simpler problems in electrolysis—familiar difficulties that occur in one's daily practice—were attacked. As regards the experiments themselves, he thought that the method of employing a capillary tube in connection with the cathode for measuring electrode-potentials, would yield as accurate results as those obtained by the author.

Dr. SAND, in reply, said the chief purpose of his work

was to show the applicability and limits of his method, although he felt the force of what Professor Threlfall had said. The capillary-tube method was useless in experiments like these, which were really diffusion experiments, as he particularly wished to avoid convection currents.

Miss BUENA POOL, B.Sc., then read a "Note on a Suggested New Source of Aluminium."

The geological data given in the paper have already been published in the *Geological Magazine* by Messrs. Holland and Warth, but the authoress thinks they are of sufficient importance to be specially brought in this form before the notice of British electro-chemists. The new source referred to in the title is India, thousands of square miles of the surface of which is covered with laterite deposits varying from a few feet to hundreds of feet in thickness. These laterites, of which four distinct classes are described in detail, are closely analogous to bauxite, the aluminium being present in the hydrated form. From specimen analyses which are quoted, it would appear that the high-level laterites in particular bear an obvious and striking resemblance to ordinary bauxite. The low-level laterites contain much free silica and clay. The conclusion of the paper is that these Indian bauxites have all the characteristics to render them commercially valuable; their pureness, ready accessibility, widespread occurrence at all elevations, and association with flowing water, pointing them out as an almost perfect source of aluminium.

Mr. W. MURRAY MORRISON said that gibbsite could not be used as a direct source of aluminium, without being first treated for alumina. He did not think that the Indian laterites were likely to be used in this country at present, as we had a plentiful supply of French bauxite to draw from, but of course they might, in time, be worked *in situ*. There was as yet no great demand for aluminium in India.

Dr. F. MOLLWO PERKIN gave a short account of the paper by himself and Mr. H. D. LAW, B.Sc., entitled "Electrolytic Oxidation of Hydrocarbons of the Benzene Series." Part I. *Hydrocarbons containing the Methyl Group.*

Owing to the more or less fragmentary style, and the incompleteness of the literature dealing with the electrolytic oxidation of organic substances, the authors have commenced a detailed study of the electrolytic oxidation of hydrocarbons of the aromatic series.

They find that when an emulsion of toluene and dilute sulphuric acid or caustic alkali is electrolysed the whole of the toluene is burnt up, but that when a mixture of acetone and toluene is electrolysed in the anode compartment of a cell, benzaldehyde is produced. Unless, however, a large excess of acetone is present, the yield of benzaldehyde is very small—even under the best conditions they were unable to obtain more than about 8 per cent of benzaldehyde. The conditions employed were 550 to 600 c.c. acetone, 50 grms. toluene, and 250 c.c. of dilute sulphuric acid. Beside benzaldehyde a small quantity of another product was produced which may be benzyl alcohol or a condensation product of the molecules of the toluene. They further oxidised ortho-, meta-, and para-xylene, and mesitylene and pseudocumene under similar conditions. In each case the corresponding mono-aldehyde was produced, with on occasion small quantities of the dialdehyde. Small quantities of a neutral product were also obtained, which are under examination. In no case was the corresponding acid produced. In the case of ortho- and para-xylene the yield of aldehyde was from 25 to 35 per cent. With the meta-xylene the yield was not above 10 per cent. Contrary to experience in ordinary chemical oxidations, the meta-xylene seems to show a greater tendency to be burnt up than the ortho- and para-xylenes.

With mesitylene and pseudocumene, the mono-aldehydes were also produced. With the latter substance, apparently a mixture of the three possible isomers. Further experiments are in progress, and the authors are also investigating hydrocarbons of the benzene series containing other

groups than the methyl group and hydrocarbons containing mixed groups.

Mr. FRANK SHEDDEN, in a written communication, suggested the use of a gas-tight cell, and determining the amount of carbon dioxide given off, to show the extent of any "burning" that might be taking place. Had the authors lowered the current density by increasing the anode surface?

Dr. PERKIN said that they had begun to make a study of the gases evolved. Their anodes were of platinum, so they had only used small ones. The chief difficulty they wished to overcome was the formation of tarry products owing to the concentration of H_2SO_4 in the anode chamber after a time. Neutralisation or withdrawal of solution were both out of the question.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxiv., No. 14, October 3, 1904.

Actinium.—A. Debiere.—Several years after the author's first publication on actinium, M. Giesel announced the existence of a radio-active substance which he called "Emanium." The striking analogy between the properties of this substance and those of actinium led the author to suppose that they might be identical. He therefore, in conjunction with M. Giesel and M. and Mme. Curie, made several comparative experiments upon the phenomena of phosphorescence produced by emanations from emanium and actinium, and obtained identical results for the two substances. Miss Brooks has also found the same number for the time constant for decrease of radio-activity produced by emanium as the author had previously given for actinium. Hence the two substances must be identical.

Properties and Constitution of Molybdenum Steels.

—Leon Guillet.—The molybdenum steels can be divided into two classes:—(1) Perlitic, (2) carbide, according to their microstructure. Experiments show that the presence of molybdenum has the same effect as the presence of tungsten upon the properties of steel, *i.e.*, it increases the tenacity, elasticity, and (in the case of perlitic steels) the resistance to crushing force. The carbide steels are extremely hard and are brittle. Four times as much molybdenum as tungsten is necessary to produce the same effect.

Thermo-chemical Comparison between Rosanilines and Leucanilines.—Jules Schmiden.—Experiments on the heats of neutralisation of the rosanilines and leucanilines have established the following facts:—1. About the same amount of heat is emitted when a triacid carbinol salt is formed from a carbinol, as when the corresponding triacid leuco-salt is formed from leucaniline. 2. The heat emitted when 3 molecules of acid react to form a coloured salt is always greater than that emitted in the formation of the corresponding carbinol or leuco-salt. Hence the instability of the carbinol salts, and their tendency to form coloured salts with the production of heat. 3. In the formation of the coloured salts more heat is emitted when the first molecule of acid reacts than when the two following molecules react, and this is more marked in the stronger bases, *e.g.*, heat produced during action of first molecule of acid to heat produced during action of second molecule = 3 : 1 in the case of rosaniline and = 6 : 1 in the case of hexamethyl rosaniline. These experiments confirm previous observations that the rosanilines, though triamines, behave like very strong monacid bases. This power of accumulating the basic properties in a single group seems to be connected with the quinone nucleus.

Berichte der Deutschen Chemischen Gesellschaft.
Vol. xxxvii., No. 13, 1904.

Action of Nitric Oxide on Chromous Salts.—V. Kohlschütter.—Three molecules of chromous chloride absorb from 1:2 to 0:87 molecules of nitric oxide, the colour of the solution changing to dark red. This was supposed to be due to the formation of the compound $(\text{CrCl}_2)_3\text{NO}$, which is very stable, absorbs no more oxygen, and does not give up NO on heating or *in vacuo*. But the author has found that this red solution gives only chromic reactions, and that nothing points to the presence in it of a NO group. Its colour slowly changes in the cold (rapidly on heating or on addition of acids) to a tint between olive-green and brownish red. The freshly prepared dark red solution was distilled with alkaline permanganate solution:—(1) Directly, and (2) after being previously warmed with hydrochloric acid, and the ammonia thus formed was determined by titration. Since alkaline permanganate decomposes hydroxylamine, if any of the latter compound were formed on acidulation the ammonia formed in the second case would be less in quantity than in the first. But it was found that the same amount of ammonia was formed in both cases. Hence, the colour change on addition of acid does not show the decomposition of a nitric oxide compound, but proves that ammonia and hydroxylamine are present in definite amounts in the red solution. Thus the absorption of nitric oxide by chromous chloride depends upon its reduction to soluble compounds—ammonia in neutral solutions or hydroxylamine in acid solutions. More chromous chloride is necessary to convert a given quantity of NO to ammonia than to hydroxylamine, and this agrees with the fact that the same chromous solution absorbs less NO in neutral than in acid solution. Nothing definite can be said regarding the nature of the red solution; perhaps it is a solution of a basic chromic salt which, like the sulphate or chloride, can pass into other hydrated forms.

Phosphorescing Zinc Sulphide.—H. Grüne.—Following Henry's directions for the preparation of zinc sulphide the author could get no uniform results in many experiments, obtaining preparations which sometimes gave stronger and often weaker phosphorescence. The more the zinc salt was purified the weaker was the blende obtained. The addition of traces of other metallic salts to the pure zinc salt gave strongly phosphorescing sulphides generally. Thus less than 1/1000 of copper gave a green phosphorescence; silver, lead, bismuth, tin, uranium, cadmium gave good preparations, while iron, nickel, cobalt, and chromium gave negative results. Manganese produced very characteristic effects. After illumination preparations of zinc sulphide containing traces of manganese phosphoresced with a reddish yellow light; rubbing or scratching caused an extraordinarily strong luminescence which could be seen even by daylight. When in the state of the finest powder the preparation phosphoresced under gentle pressure. Preparations containing other metals, *e.g.*, copper or uranium, showed this kind of phosphorescence, but to a much slighter extent.

Quantitative Determination of Active Oxygen in Organic Persulphates.—A. Wolf and R. Wolfenstein.—In inorganic persulphates the active oxygen is determined by heating a weighed amount of the persulphate with a solution of Mohr's salt and titrating the unoxidised part with *n/10* permanganate. This method cannot be used for organic persulphates, for even supposing the Mohr's salt is readily oxidised the excess cannot be titrated with permanganate on account of the presence of the organic substance. The following method depending on the oxidation of sulphurous to sulphuric acid by means of the persulphate was devised to obviate this difficulty:—A saturated aqueous solution of sulphurous acid, to which some barium chloride had been added, was filtered and heated in an Erlenmeyer flask with a weighed quantity of persulphate and some hydrochloric acid. On cooling the BaSO_4 formed was filtered off and weighed:

$\text{H}_2\text{S}_2\text{O}_8 + \text{SO}_2 + 2\text{H}_2\text{O} = 3\text{H}_2\text{SO}_4$. In calculating the active oxygen it must be remembered that the available oxygen is only responsible for the formation of one-third of the total BaSO_4 obtained, as shown by the equation.

Action of Acid Dyes on Wool Fibres.—Edmund Knecht.—The elaboration of an accurate method of estimating azo dyes and certain nitro dyes has enabled the author to establish the fact that the so-called acid dyes are taken up in the proportion of their molecular weights when wools are coloured by them. Mixtures of the wool with 50, 25, &c., per cent of dye and 30 per cent sulphuric acid were heated for an hour. The amount of sulphuric acid was arbitrarily chosen, and seems to have no influence on the amount of dye taken up. Nor does the quantity of water employed seem to affect the amount of dye taken up by the fibre within fairly wide limits (50 to 200 times the weight of wool). This fact directly contradicts a solution theory. Moreover, the solubility of the dye in water does not influence the amount taken up. Five different classes of dyes were examined:—Orange G, Ponceau 2G, Orange II., Acid Magenta, and Picric Acid and its homologues, and in all cases they were taken up by the fibre in the proportion of their molecular weights. The sulphuric acid not only sets free the dye from its salt, but also acts upon the fibres so as to increase their power of taking up dye.

Luminescence of Sidot's Blende under the Influence of Ozone.—Rudolf Schenck and F. Mihr.—Certain analogies exist in the behaviour of ozone and of radio-active substances, *e.g.*, both form gaseous ions (if only to a slight extent in the case of ozone) on decomposition, which manifest themselves in the same way, *i.e.*, in the discharge of an electroscope and the vapour radiation phenomenon. Sidot's blende also becomes luminescent under the influence of ozone. The authors have previously found that the ozone converts the zinc sulphide into sulphate, and thus it is an oxidation luminescence similar to that of other oxidisable substances in ozone. They described the luminescence as nebulous, *i.e.*, a bright cloud seemed to extend over the blende in the current of ozone. On repeating the experiments under improved conditions they find that the phenomenon of scintillation is visible as well as the homogeneous luminescence of the preparation. Quite unused fresh blende, which had been carefully kept from any radio-active substances, was used for the experiments. Strips of paper prepared with this blende were kept in a closed cardboard box in the dark room for some time, then cut up in red light, and introduced into the apparatus. The authors first observed the blende preparations without passing the current of ozone through the apparatus, and without starting the inductor. In the first quarter of an hour, and generally the second too, nothing was to be seen, but gradually spots of light appeared flashing on all preparations, which became clearer. They could be seen either with a microscope or with the naked eye (a very short-sighted eye is best suited for this purpose). When unozonised oxygen was passed through the apparatus no alteration whatever occurred in the phenomena observed. The eye very soon becomes tired in observing this phenomenon, and must be rested to avoid errors in estimating the comparative brightness. Thus, Sidot's blende scintillates feebly without any radio-active substance. Soon after the inductor had been started for the production of ozone it was seen that the number of spots of light increased, and the intensity of the sparks also. The experiments were repeated, always with the same results. The authors found that feeble illumination, *e.g.*, with the help of a match, increases the scintillation. Thus it appears that all factors which cause Sidot's blende to luminesce homogeneously also excite the scintillation; an increase of scintillation does not necessarily show the presence of a radio-active substance and Sidot's blende is a reagent which must be used with great care. When frequently treated with ozone it no longer gives the homogeneous luminescence, but distinct scintillation can always be seen in such preparations.

THE CHEMICAL NEWS.

Vol. XC., No. 2346.

NOTE ON THE HIGHER GLYCERIDES.*

By J. B. HANNAY, F.R.S.E., F.I.C.

(Concluded from p. 225).

SEVERAL analyses of the lead compounds formed by treatment of the new compounds with water proved them to be basic salts of the formula—

where F represents the radical of the fatty acid.

A mean of four analyses of the dehydrated basic oleate and linoleate gave 41.68 per cent of lead for the oleate as against 41.73 required by theory, and 41.96 for the linoleate as against 41.87.

To ascertain if the basic oleate and linoleate so obtained could be formed directly, a weighed quantity of the acids was mixed with sufficient oxide of lead to form a normal salt, and the moisture evolved was weighed. 7.5415 grms. of oleic acid gave off 0.2540 H₂O. Theory requires 0.2406. Another molecular proportion of PbO was then added, and heat applied. When it was completely dissolved there had been evolved only 0.0070 grm. H₂O, showing that the second molecule is simply an additive compound to form the basic salt.

Similar results were obtained with linoleic acid, but the full quantity (or an excess) of oxide of lead was added at once, with the result that invariably only half the water represented by the litharge combined was evolved.

Mercury thymol acetate forms a double compound with mercury acetate, and it was attempted to ascertain if an analogous compound was formed between lead glyceryl oleate and lead acetate. As anhydrous lead acetate is insoluble in hydrocarbons, while the glyceryl compound is very soluble, an easy method was afforded of separating these substances. Molecular proportions of the two were fused together, and on cooling they formed a homogeneous mass, which was freely soluble in benzene, chloroform, &c., showing that no free lead acetate existed in the material. The solution was partially precipitated with absolute alcohol. The precipitated portion was collected and dried, and the part remaining in solution evaporated to dryness, and the two analysed.

The lead acetate contained	63.69	per cent Pb
The lead glyceryl oleate	39.99	"
The double compound should contain ..	44.08	"
The precipitate gave	44.21	"
The soluble portion	44.05	"

The result is high, but the acetate becomes basic when the water is driven off, and the mixture gave 44.06 per cent Pb, so that the fractional precipitation did not split up the compound, and this affords confirmation of the analogy with mercury thymol acetate.

The lead in the lead glyceryl oleate is not attacked by sulphur nor phosphorus in carbon disulphide, nor by phosphorus pentoxide, nor sulphur trioxide, nor is it displaced by fusing the compound with metallic sodium.

The lead glyceryl oleate and linoleate were digested with carefully dried absolute alcohol for periods up to two hours, but no trace of glycerin was extracted, showing that the ester had been in no way split up. Of course any water

in the alcohol at once completed the saponification of the oil, and the glycerin was set free.

Experiments were made to ascertain if hydrate of lead, or carbonate of lead, or any of their combinations known as Dutch white lead, can combine in the cold with triolein or trilinolein, and they have shown that no action takes place with any of these bodies, even if the mixture be kept (as has been done in these experiments) for a period of nine years.

Sodium carbonate reacts with oils, but at a very much higher temperature; carbon dioxide being freely evolved at 270° to 290°, and the oil much blackened. The resulting combination is a tough leathery body, quite unlike the lead compound. The sodium being monovalent, the reaction most probably forms tri-sodium glycerin and oleate of sodium, thus—

Action of Sulphur Chloride on Glycerides.

It was found, contrary to the indication of other experimenters, that under proper conditions the amount of sulphur chloride capable of combining with any oil was in the exact proportion required to saturate the free linkings of the acid radicals, and thus exactly parallel with the bromine or iodine absorption, taking S₂Cl₂ as divalent. To clear up the matter the iodine, bromine, sulphur chloride, and oxygen absorptions of pure oil and linsed oils were determined.

The oxygen absorption was conducted on thin silver trays with a surface of about 100 square centimetres, and the oil was spread in a layer of from 0.025 to 0.035 grm. per square centimetre, as it was found that thicker layers absorbed the oxygen more slowly, and their lower layers were protected from oxidation by the upper oxidised layers.

In 115 days at summer temperatures, from June till September, linsed and poppy oils had absorbed practically all the oxygen they were capable of fixing.

The olive oil was spread very thinly on lead, in an atmosphere saturated with moisture, as it showed no signs of drying on silver, and did not cease to gain weight, even at the end of three years' exposure on lead. Many conflicting statements and empirical experiments are to be found as to the action of sulphur chloride on oils. After some experimenting it was found that the causes of the differences lay in the use of various diluents, adding an insufficient quantity of the chloride, and in allowing the temperature to rise, which results in the chlorine of the sulphur chloride attaching itself to the glyceryl radical, and in forming substitution compounds with the hydrogen of the acid radical, giving rise to chlorhydrins and hydrogen chloride.

By cooling the materials in ice and keeping them cooled while mixing, they slowly form a jelly, and no by-products are formed.

The combination was prepared in two ways:—

1. By mixing the materials in molecular proportions; i.e., three of sulphur chloride to one of the triolein, and six of sulphur chloride to one of trilinolein.
2. By using an excess of sulphur chloride and placing the solid in a desiccator over sticks of caustic potash to absorb the excess of sulphur chloride.

The compounds formed by these methods were analysed by boiling with strong nitric acid in a Jena glass flask. About one-third of the chlorine comes over as nitrosyl chloride, and is retained by being passed into a solution of alkali, while the sulphur, which attached itself to the acid radical, forms a sulphonic acid. This is rendered alkaline by sodium carbonate, a little nitre added to ensure excess of oxidising agent, and the whole evaporated to dryness, and fused in the same flask, and the chlorine and sulphur estimated as silver chloride and barium sulphate.

The substance prepared as above gave:—

* The substance of a Paper read before the Chemical Society.

	Found.		Theory.	
	S.	Cl.	S.	Cl.
For the olein compound..	14.04	15.47	14.89	16.52
For the linolein compound	21.42	23.21	22.74	25.23

When prepared and left at ordinary temperatures fumes were given off, and the composition was :—

Linolein compound..	S = 24.92	Cl = 19.17
Boiled with CS ₂ and filtered it was further decomposed ..	S = 21.45	Cl = 13.29

Showing that sulphur was comparatively firmly fixed, while the chlorine was driven off.

To make these results comparable, the olein has been taken as having six free bonds (absorbing 6 of Br), and the linolein as having twelve, although both oils usually contain from 5 to 10 per cent of other oils—stearin and palmitin in olive oil, and olein in the linseed oil, which lower the saturation equivalent. The following shows that the compounds formed by iodine, bromine, oxygen, and sulphur chloride are all formed by the saturation of the same free linkages, as shown by the structural formula on p. 224 :—

Olein taken.	Saturated by—	Per cent.	Theory.	Percentage of theoretical.
2.1725	Iodine 1.7923	82.5	86.2	95.7
2.2650	Bromine 1.1800	52.1	54.3	95.9
1.8273	Oxygen 0.0895	4.9	5.4	90.2*
13.2725	Sulphur chloride 5.7735	43.5	45.8	94.9

Linolein taken.

2.0840	Iodine 3.2593	156.4	174	89.8
3.6615	Bromine 3.6254	99.1	109.3	90.9
1.8580	Oxygen 0.1801	9.69	10.9	88.9*
2.5205	Sulphur chloride 2.1065	83.5	92.3	90.4

* Action not complete.

From these figures it is clear that the sulphur chloride and oxygen saturation numbers are caused by the combination with the same unsaturated linkages as combine with the iodine or bromine. One would expect it to be so, but as much mystery surrounds the sulphur chloride compound in most of the published researches, it was thought worth while to make an exact examination. The numbers quoted are taken out of many trials conducted over several years.

It was found that the lead glyceryl compounds described in the first part of this paper were capable of forming the insoluble sulphur chloride combination, but it was less stable than that with the free oil, so the point of saturation was determined by the failure of the sulphur chloride to produce any further precipitate in a solution of the lead glyceryl compound in a hydrocarbon solution. The bromine saturation numbers were determined at the same time.

Lead glyceryl oleate taken.		Per cent.	Theory.	Per cent of theoretical.
2.7590	Bromine	0.7863	28.51	30.91
3.0050	S ₂ Cl ₂ ..	0.7150	23.8	26.01
				91.5

Lead glyceryl linoleate taken.					
2.1115	Bromine	1.1782	55.8	62.05	90.0
2.6040	S ₂ Cl ₂ ..	1.2265	47.1	52.3	90.1

These numbers show that here again we have a close approximation to the theoretical figures, showing that the same bonds are active in the lead compound, as in the original oil.

The saturation of the free linkages of the acid radicle by oxygen gives a solid compound in the case of both oleic and linoleic glycerides; the latter forming "linolein," the solid pellicle familiar in paints, and having the composition C₅₇H₉₈O₁₂, the oil taking up 6 of oxygen to saturate the free linkages, as at Position 3, p. 224.

The lead glyceryl oleate and linoleate compounds with bromine and sulphur chloride may be represented thus :—

It seemed strange that, during these researches, carried out over a period of nine years, in all the samples of linseed and poppy oils, and the acids prepared from them, there never was the slightest indication of Hazura's linolenic and isolinolenic acids, supposed to have an iodine absorption power showing six linkings, *i.e.*, eighteen free bonds in the triglyceride. In every case the iodine absorption has been a little below that due to linoleic glyceride, *i.e.*, twelve free linkages, the deficiency being due to oleic and perhaps traces of palmitic glycerides.

Hazura gives the composition of the acids from the glyceride called linseed oil as :—

	Per cent.	Iodine absorption.	
		As glycerides.	As free acids.
Linoleic acid ..	15	26	27
Linolenic acid ..	15	39	41
Isolinolenic acid ..	65	170	178
Saturated acid ..	5	0	0
	100	235	246

Now the highest absorption for linseed oil or the acids directly derived from it by any experimenter is 160, and Hazura himself gives 156, a value quite inconsistent with the existence of linolenic and isolinolenic acids, while the theoretical number for pure triolein is 174, so that Hazura's number shows a deficiency of about 8 per cent due to impurities, and agreeing well with all my figures before given. In these investigations over 200 samples of pure linseed oil have been brominated or saturated by Hübl's method with iodine, and not one gave an iodine number over 160; and over forty samples have been saponified, and the acid or acids saturated with bromine or iodine, but in no case was a higher iodine number than 166 obtained (or 100 in the case of bromine), which are again well under the numbers (181 and 114) for the absorption numbers of linoleic acid.

As Hazura gave an iodine number for linseed oil (156) agreeing with all other investigators, and well under the number for an acid with four free linkages, and yet found acids (after hydrolysis and reduction of those obtained from the same oil), which showed iodine numbers indicating acids with 6 free linkages, an investigation into the real meaning of Hazura's numbers seemed imperative, as I had been unable to find any trace of these highly unsaturated acids by any means of saponification, alcoholic or otherwise, which I had tried.

Suspecting that the acids obtained by Hazura from the alkaline permanganate treatment were products of decomposition of the linoleic acid from over oxidation, a series of experiments were instituted, under which the acids from linseed oil were exposed to the action of alkaline permanganate varying in three directions, *viz.*, time, concentration, and temperature.

The method was to make the mixture, allow to stand a given time, then dilute to the same volume in every case, and reduce or raise the temperature to 16°, then filter off the oxy acid formed, and dry it in a desiccator, and weigh it.

It was soon apparent that great dilution of the acid soap led to the oxidising action going too far; in fact, beyond

the mere saturation (or hydrolysis) of the oxy-acid, and that it struck more deeply and formed acids of the azelaic type, and the yield of oxystearic acid was diminished. A rise of temperature led to the same result, as did large excess of permanganate and a longer time; but the insoluble acid obtained never showed a higher acetyl value, determined by Lewkowitsch's method, than corresponded to the tetra-oxystearic acid. The greatest yield of the oxy-acids, which sometimes reached 92 per cent of the theoretical, was obtained by treating the acid soap with a rather concentrated solution of the permanganate (about 4 per cent giving good results) and allowing it to stand with an excess at 0°, when a good yield is obtained. Hazura's method of isolating the isolinolenic acid by brominating the acids in acetic acid solution yields very complex results (substitution products being formed, and a large excess of bromine being required), but if brominated carefully in chloroform, taking care to add a very slight excess of bromine, the bromo derivative, on being reduced by zinc and acid, yields only the original linoleic acid with an iodine value of 170 or under, according to the purity of the original oil used.

These experiments have been repeated with poppy oil and hemp-seed oil with similar results—no acid with a higher value than I_4 was formed—and this agrees with the results of Reformatzky (*Ann. Russ. Chem. Soc.*, xxi., 202) who found that pure linoleic acid, prepared from its ethyl salt, gave only a hydroxy acid of $(OH)_4$, and no linolenic or isolinolenic acids; but that permanganate oxidation at ordinary temperatures always produced some products of deep oxidation, as azelaic and formic acids.

Hence the conclusion is that in natural vegetable oils the highest iodine value is one of I_4 in linoleic acid, and that the linolenic and isolinolenic acids, if they exist, are products derived from linoleic acid by the replacement of some of the hydrogen of some members of the methane chain, by hydroxyl derived from the oxygen of the permanganate.

A MODIFIED FORM OF THE PERSULPHATE METHOD OF ESTIMATING MANGANESE IN IRON AND STEEL.

By H. PROCTER SMITH, F.C.S.

The estimation of manganese in iron and steel may be performed in many different ways, but in the author's opinion, for accuracy, speed, cleanliness, and cost, nothing beats the persulphate method.

The following modification gives most satisfactory results, and may be used for all classes of iron and steel:—Weigh into a 6" x 1" test-tube 0.2 gm. of the sample and the same weight of a steel, the amount of manganese in which has been previously determined by a gravimetric method; add from a burette 10 c.c. nitric acid (1.2) to each, and dissolve by heating over a small flame; boil until all red fumes are driven out of the tube, then add 10 c.c. of the silver nitrate solution, and about 1 gm. of solid ammonium persulphate dropped into the solution by means of a spatula; warm gently over flame until the salt is nearly dissolved; then wash any salt remaining on the sides of the tube down, and place in a bath of cold water. When perfectly cold the pink solution is washed into a clean porcelain dish, and titrated with the standard solution of sodium arsenite until one drop turns the solution from a pinkish tinge to a very pale green. The strength of the arsenite is determined each time by means of the standard manganese steel, and thus a factor obtained; e.g., a steel containing 0.45 per cent of manganese took 4.3 c.c. of arsenite, then $0.45 \div 4.3 = 0.105$. Then number of c.c. of arsenite for any other steel multiplied by 0.105 = percentage of manganese in the steel.

The change from the pinkish colour to the green is most

marked, and cannot be missed by an operator, even when using the method for the first time. With pig-iron there is no need to filter off the graphite, as it does not interfere with the titration. Should a titration be overdone, it can easily be brought back to the original state by adding a further portion of ammonium persulphate and gently warming, when the pink colour is restored, and after cooling may be re-titrated.

Silver Nitrate Solution.—Pure silver nitrate, 1.70 grms.; distilled water, 1000.0 c.c. This is approximately a centinormal solution.

Sodium Arsenite Solution (stock).—Pure arsenious acid, 5 grms.; pure bicarbonate of soda, 15 grms. Dissolved by boiling in 250 c.c. water, and diluted to 1000 c.c. when cool.

For use:—40 c.c. of above diluted to $\frac{1}{2}$ litre, when 1 c.c. = approximately 0.1 per cent manganese.

The following comparative results taken at random from the author's note-books confirms the accuracy of the method:—

	Gravimetric method. H ₂ O, %.	Gravimetric method. Mn per cent.	Ford and Williams HNO ₃ + KClO ₄ Mn per cent.	Lead peroxide. Com- parison of colour. Mn per cent.	Ammonium persul- phate. Titration with arsenite. Mn per cent.

This process can easily be worked to give the manganese contents in any steel in under fifteen minutes from commencing to weigh out the sample, and hence is particularly useful where the manganese is required before tapping a basic open-heat where manganese ore has been used in "feeding."

Shotton, Flint.

VOLUMETRIC ESTIMATION OF VANADIUM AND CHROMIUM IN SOLUTION TOGETHER.

By EM. CAMPAGNE.

THE quantitative separation of vanadium and chromium is very difficult on account of the numerous properties common to both of these elements. The methods of estimation proposed up to the present have been recently the subject of a paper by M. Nicolardot, who has recommended a method based on the separation of the chromium in the form of the very volatile chloride of chromyl.

All these old methods have the drawback of requiring an effective separation of the two elements before coming to the estimation proper. This separation can only be effected after long and delicate manipulations, so that methods based on this principle do not seem to us to answer to the requirements of analyses for commercial laboratories.

A consideration of certain known reactions has led us to devise a method for the volumetric estimation of these metals, which has the advantage of not requiring their previous separation, and of being applicable even in the presence of small quantities of other metals.

Further, this method of estimation is closely connected with the method of estimating vanadium we have described recently (*Comptes Rendus*, 1903, vol. cxxxviii., p. 570); it can be applied to the vanadiferous minerals and to ferro-metallic alloys.

To detect chromium in the presence of vanadium, a few grms. of the mineral (or the oxides resulting from the careful calcination of the nitrates obtained by attacking the alloy with nitric acid) are fused with a mixture of nitrate and carbonate of soda in equal parts.

The mass is taken up with water; the metallic oxides, that of iron amongst others, remain insoluble, and the solution contains the vanadium and the chromium in the form of vanadate and chromate.

Acidulate with sulphuric acid, and take a few c.c. and shake in a test-tube with a little peroxide of hydrogen and ether. If the two metals are present the aqueous solution takes a blood-red colour (vanadium), and the etherial solution a very intense but fugitive blue (chromium). In the contrary case neither one nor the other of these reactions is observed.

Successive Estimation of Vanadium and Chromium.

If we have to do with a metallic alloy (ferrochromo-vanadium) we attack with nitric acid, gently calcine the nitrates to obtain the corresponding oxides, which are dissolved in concentrated hydrochloric acid. The proportion of iron generally being considerable, it is eliminated by Rothe's method (treatment of the chlorides by ether). As far as concerns the details of the attack and the method of procedure, we refer the reader to our previous paper already quoted.

The aqueous solution obtained by this treatment contains all the chromium and vanadium that was present in the alloy or mineral, besides small quantities of ferric chloride. This solution of chlorides is evaporated several times in the presence of a large quantity of concentrated hydrochloric acid, so as to bring the vanadium into the state of oxychloride, VOCl_2 , and the chromium into the state of chloride, Cr_2Cl_6 . If the original solution was a mixture of chromate and vanadate, the reduction should be conducted in exactly the same manner; for the reduction to be complete, it is important that the solution should not contain any free sulphuric acid.

After the reduction the solution is treated with 10 c.c. of pure sulphuric acid and evaporated on the sand-bath until white fumes begin to appear. Thus we obtain sulphate of chromium, $\text{Cr}_2(\text{SO}_4)_3$, and the blue divanadyl sulphate, $\text{V}_2\text{O}_2(\text{SO}_4)_2$.

The estimation of the vanadium is based on the fact that the divanadyl sulphate is oxidised rapidly, and in the cold by permanganate of potassium, while the sulphate of chromium remains perfectly stable under these conditions.

The cooled sulphuric solution is diluted with 250 c.c. of distilled water, and then titrated at the ordinary temperature with a solution of permanganate of potassium. The decoloration of the solution is rather slow at first, but can be hastened by stirring frequently. The oxidation of the salt of vanadyl is complete when the rose-colour of the KMnO_4 persists for several minutes in spite of the stirring, and when a drop or two of permanganate will make it reappear.

This titration completed, we add a large excess of permanganate (5 or 10 c.c. of a 1 per cent solution), and boil briskly so as to change the sulphate of chromium into chromic acid; the solution ought to remain rose-coloured on account of the excess of the oxidising reagent, an excess which is subsequently got rid of by the addition of a few pieces of filter-paper and further boiling. After cooling, the solution is filtered to separate the binoxide of manganese formed, and we obtain a solution of vanadate and chromate having the characteristic yellow colour of the latter salt.

To this solution we add a known quantity of a solution of Mohr's salt, titrated with permanganate, to reduce the chromic acid. Finally, we titrate the excess of the ferrous salt added, by means of permanganate. The amount of chromium present is calculated from that of the ferrous salt oxidised by the chromic acid, which is itself given by the difference between the amount of permanganate corresponding to the volume of ferrous salt introduced and that absorbed by the solution.

The following equations explain these reactions:—

1. Estimation of the Vanadium:—

2. Estimation of the Chromium:—

In reality we do not titrate the ferrous sulphate in excess, but the divanadyl sulphate resulting from its action on the vanadic sulphate:—

The consideration of this equation and of Equation 1 shows that the final result is exactly the same, the divanadyl sulphate reducing the same amount of permanganate as the ferrous sulphate which brings it into existence.

The results of this method are not influenced by the presence of small quantities of iron in the state of ferric sulphate in the original solution. When the proportion of chromium is much greater than that of the vanadium, it is necessary to use only a small quantity of the material, as the green colour of the sulphate of chromium tends to diminish the sensitiveness of the appearance of the rose tint due to a slight excess of permanganate.

The results obtained by observing this precaution are as exact as those which could be obtained by applying each of the two processes used separately, and which are very exact even by themselves.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 16.

THE IODOMETRIC DETERMINATION OF GOLD IN DILUTE SOLUTION.*

By RALPH N. MAXSON.

In a former paper from this laboratory (Gooch and Morley, *Am. Journ. Sci.*, 1899, viii., 261) it was shown that, under suitable conditions, potassium iodide acts normally upon auric chloride according to the equation—

and it appeared that this reaction may serve as the basis of a trustworthy method for the determination of small quantities of gold—the freed iodine being estimated by careful bleaching with sodium thiosulphate and the final addition of standard iodine to the incipient coloration of the starch indicator, rose in most cases, or only blue at the outset when the starch has not undergone hydrolytic change (Hale, *Am. Journ. Sci.*, 1902, xiii., 379). Three series of experiments were made upon solutions of auric chloride standardised by the ferrous sulphate method and by the method of Vanino (*Ber.*, xxxi., 1763), and one series upon auric chloride made from pure gold foil.

In the first series the solutions of auric chloride (0.8710 gm. to the litre), sodium thiosulphate (nearly N/100), and iodine (nearly N/100) were of such strength that an inaccuracy of 0.01 c.m.³ in measurement would correspond to about 0.00009 gm. for the gold solution and to a little more than 0.00001 gm. in terms of gold for each of the other solutions. It is hardly to be supposed that individual readings can uniformly approximate the truth within 0.01 c.m.³, and as there are six readings to be made in every complete determination, the chances for inaccuracy amounting to several hundredths of a milligram of gold—dependent to a great extent as to direction and amount upon the personal equation of the operator—are considerable. Should all these reasonable errors chance to lie in

IV.	14	0.520	to 0.052	N/1000	N 10000	0.052	+0.002	+0.01	-0.008

the same direction, the cumulative errors are likely to reach at least ± 0.00005 grm., and may be even more.

The actual error, due to all causes, found in the first series of twelve determinations, excepting a single determination manifestly not in line with the others, and tending to make the average error smaller, amounted in the mean to -0.00005 grm. of gold between extremes of $+0.00003$ and -0.00010 grm.

In the second series of twenty experiments, in which the solution of gold was ten times as dilute as in the experiments of the first series, the other solutions being of the original strength, the total average error actually observed was considerably lower, as would be expected, and amounted to $+0.00002$ grm. of gold between extremes of $+0.00006$ grm. and -0.00002 grm.

In a third series of ten experiments, in which the dilute gold solution (0.0871 to 1 litre) was used, nearly N/1000 iodine and nearly N/1000 thiosulphate were employed. The average error amounted to less than 0.000004 grm. between extremes of $+0.000020$ grm. and -0.000029 grm., but in these determinations the sensitiveness of the starch indicator to iodine becomes an important factor, and it was necessary to introduce a correction of 0.1 c.m.* for the amount of the N 1000 iodine necessary to bring out the starch reaction in the volume of liquid used when tested in blank.

In still another series of fourteen experiments, made upon a gold solution (0.0104 to 200 c.m.*), prepared by dissolving pure gold-foil in chlorine water and destroying the free chlorine by ammonia, the average error amounted to $+0.000002$ grm. between extremes of $+0.00001$ grm. and -0.000008 grm.

The results of these experiments may be summarised as shown in Table I.

It is plain that the average experimental errors, due to all causes, do not very much exceed the errors which might naturally be expected to arise from errors of reading. In repeating the work of Gooch and Morley I have obtained results of a reasonably similar order of accuracy. The process has, however, been recently criticised unfavourably by Rupp (*Ber.*, xxxv., 2011) on the ground that the percentage errors are found to be large. It is to be noted, however, that large percentage errors are inevitable in the application of volumetric methods to the determination of total weights measured in hundredths of a milligram, or tenths of a milligram, or even in a few milligrams, inasmuch as the reasonable errors to be expected in the measuring of solutions strong enough to be visibly reactive are of themselves large when reckoned as percentages of small absolute amounts. These errors, small as they are, Rupp attributes to the secondary reactions of potassium iodide on aurous iodide, in which gold is reduced and iodine set free. I have been unable, however, to find evidence of such action under the conditions of experimentation during periods much longer than those required for the completion of the analytical process. Thus aurous iodide, obtained by treating a solution of auric chloride containing 0.025 grm. of gold, with potassium iodide according to the directions of Gooch and Morley, adding starch, and bleaching the starch with sodium thiosulphate, gave no colour of starch blue after the interval of an hour. A second similar experiment gave the same result. Inasmuch as an interval of ten minutes is enough for the complete manipulation of a single determination, it is plain that the stability of the aurous iodide does not figure in the accuracy of the determination of the small amounts of gold for which the process was designed.

As a substitute for the method described by Gooch and Morley, and sustained by the fifty-five analytical determinations mentioned, Rupp announces a process for the estimation of gold depending upon the precipitation of that element from auric chloride by means of standard arsenious acid in excess, according to the equation—

and the titration of the excess of arsenious acid by iodine. To show the reliability of the process Rupp cites six determinations, in one of which the titrations were made in two portions. Four of these six deal with 6.12 m.grms. of gold each, while in two the gold amounted to 6.1 m.grms. These figures, which cover the entire range of the amounts used in Rupp's analytical determinations, do not represent the order of magnitude or range of the amounts of gold handled by Gooch and Morley, which varied from 8.7 m.grms. to 0.052 m.grm. Only two determinations upon amounts comparable with those used by Gooch and Morley were made, and in only these two were suitably dilute solutions of iodine (N/100) and of arsenious acid (N/100) employed.

The gold solution employed in all the determinations was of such strength that a single error of 0.01 c.m.* in reading would amount to an error of 0.00006 grm. of gold; while the arsenious acid employed in three determinations was so strong (N. 2) that an inaccuracy in reading to the extent of 0.01 c.m.* would introduce an error of 0.0003 grm., actually greater than the whole amount of gold involved in each of the individual determinations of the greater part of the entire series of Gooch and Morley, and nearly six times greater than their minimum amounts. It is plain, therefore, that Rupp's experiments do not relate to the small amounts of gold handled by Gooch and Morley, and that experiments made with such solutions as Rupp employed cannot form a basis upon which to found a method for the determination of the very small amounts of gold determined by Gooch and Morley.

It has seemed to be desirable, therefore, to submit the process of Rupp to further investigation. In these experiments the procedure of Rupp was followed in general, but the reagents were all used in solutions reasonably dilute, as must be the case if accuracy is to be attained. The gold solution used was prepared from pure gold chloride, and was carefully standardised by means of metallic magnesium, and electrolytically with the revolving cathode, according to the method of Gooch and Medway (*Am. Journ. Sci.*, 1903, xv., 320). The solution contained 0.0580 grm. of metal in 1 litre, and was free from nitric acid. The arsenic solution was N/100, and was made by properly diluting a standard solution of N/10 arsenious oxide. The iodine solution used was approximately N/100, and was made by properly diluting an iodine solution, which had been carefully standardised against the N/10 arsenic solution mentioned above.

In reducing and determining the gold the procedure was as follows:—A measured quantity of the slightly acid solution of standard auric chloride was drawn from a burette into a 100 c.m.* graduated flask, and to this was added a measured excess of a standard solution of arsenious acid dissolved, as usual, in acid potassium carbonate. In every case the excess of the arsenious acid was considerable, and the acid carbonate introduced simultaneously was enough to more than neutralise the slight acidity of the auric chloride. Rupp states that the reduction takes place in acid solution, but I have been unable to effect the precipitation of the gold when free acid is present, but from a

solution made so acid that the carbonate present in the standard arsenic is insufficient to neutralise the free acid, the gold may be precipitated upon the further addition of a suitable amount of acid potassium carbonate. The flask containing the gold, the arsenite, and the acid carbonate was heated thirty minutes upon a steam-bath, then cooled and filled to the 100 c.m.³ mark. Measured portions of the solution, 25 c.m.³ each, were titrated with the standard iodine in presence of acid potassium carbonate and potassium iodide. The details of these experiments are shown in Table II.

A comparison of the figures obtained in the individual titrations of portions of a single reduction show that the difference due to the errors of analysis are reasonably small, rarely exceeding a few units in the fifth decimal place—or a few hundredths of a milligram. The errors of the process, however, computed by comparing the average of these single determinations with amount of gold actually taken, range from -0.6 m.grm. to +0.65 m.grm., are wholly irregular, and are approximately ten times as large, reckoned absolutely or in percentages, as the errors obtained by Gooch and Morley when handling similar amounts of gold. So far as the evidence of these experiments goes, it is plain

that the process of Rupp is wholly untrustworthy for the determination of the very small amounts of gold concerned.

I take this opportunity to thank Prof. F. A. Gooch for much kindly aid and advice in the preparation of this paper.

THE LIMIT OF ERROR IN THE VOLUMETRIC DETERMINATION OF SMALL AMOUNTS OF GOLD.*

By RALPH N. MAXSON.

In a former paper from this laboratory, Gooch and Morley (*Am. Journ. Sci.*, 1899, [4], viii., 261) established the accuracy of a method for the determination of small amounts of gold, based upon the reaction—

Recently the attempt has been made by Rupp (*Ber.*, xxxv., 2011) to show that this method is inaccurate, and to bring forward a process based upon the reduction of gold by standard arsenious acid, and titration of the residual arsenious acid by standard iodine. In a study of these two methods (*Am. Journ. Sci.*, 1903, [4], xvi., 155), I have verified the results obtained by Gooch and Morley, but have been unable to determine similar amounts of gold with even approximate exactness by the method of Rupp.

More recently, Rupp (*Ber.*, xxxvii., 3961) has disclaimed accuracy for his method when applied to amounts less than a few milligrams, and proceeds to discuss the absurdity of attempting to determine volumetrically tenths and hundredths of a milligram of material, however accurate the method may be—and this in the face of his statement, in his own previous paper, of volumetric results carried to thousandths of a milligram.

While quite in agreement with Rupp so far as to admit the absurdity of attempting to determine amounts of material measured in tenths and hundredths of a milligram by means of N/2 arsenious acid, as did Rupp in three out of the six determinations upon which he rested his process, I take the view, that with properly made standard solutions of suitable dilution, it is quite possible for a skilful analyst to determine tenths and hundredths of a milligram of material.

By the use of approximately N/100 iodine and thiosulphate, Gooch and Morley got results with a mean error of 5/100 milligram. between extremes of +3/100 milligram. and -10/100 milligram. in twelve determinations, a single small divided drop of the iodine solution and of the thiosulphate solution being sufficient to produce an immediate reaction with starch, and a bleaching of the starch colour, respectively.

When using N/1000 solutions of iodine it was necessary to add to the volume used 0.1 c.m.³ of iodine, in order that the first small drop of gold should bring out the starch reaction. This was a perfectly definite correction, and was equivalent to 1/100 milligram. of gold. With N/1000 solutions and with the application of this correction, ten experiments gave a mean error of less than 4/1000 milligram. between extremes of +2/100 milligram. and -29/1000 milligram; while in another series of experiments in which the start was made with pure gold foil, dissolved in chlorine water and treated by a process carefully described, the average error of fourteen determinations was +2/1000 milligram. between extremes of +1/100 milligram. and -8/1000 milligram. This is not theory; it is experiment. Here are volumetric solutions capable of showing 1/100 milligram., or less, of gold. Is it any more absurd to determine gold in this manner than to weigh that element upon an assay balance sensitive to 1/100 of a milligram? To be consistent, Rupp should include all processes, gravimetric as well as volumetric, in his sweeping declaration.

* Contributions from the Kent Chemical Laboratory of Yale University. From the *American Journal of Science*, xvii., No. 102.

The fact that large percentage errors occur in certain determinations made by Gooch and Morley, upon small amounts of gold, is again made the subject of criticism by Rupp.

As I have previously stated, every analytical process has a certain inevitable error, and because of this fact as we approach the limit of accuracy of the process the percentage error will increase rapidly. This increase can, however, under no circumstances be considered a reason why small quantities of substances should be disregarded in analysis, either volumetric or gravimetric. Because the ordinary analytical balance is sensitive only to 1/10 or 1/20 milligram, is no reason for declining to weigh tenths or twentieths of a milligram, although the percentage error in weighing such amounts may be very large.

Besides these wholly unreasonable criticisms, reference is made by Rupp to some matters of scientific fact, and to these I next propose to give attention.

To Rupp's statement that with dilute solutions the starch indicator is no longer reliable, it is sufficient to reply that experience has shown that one small drop of N/100 iodine solution develops the starch colour at once, in solutions of the volume and concentration described; and if N/1000 solutions be used, a perfectly definite, and not excessive allowance of 0.1 c.c., equivalent only to 1/100 milligram, of gold, is all that is needed.

Further, Rupp claims that the decomposition of aurous iodide is the greatest error of the process of Gooch and Morley, and refers to the handbooks of chemistry to substantiate this opinion. No handbooks are known to me which discuss the deportment of aurous iodide under exactly the conditions of this analytical process, but a study of the reaction, of which I made mention in a former paper (*loc. cit.*), showed that aurous iodide possesses stability sufficient for the purposes of the analytical process.

I have, however, thought the matter of sufficient interest to warrant further investigation concerning the deportment of this salt under more varied conditions.

The method employed to determine the rapidity with which the aurous iodide decomposes was as follows:—A measured quantity of a standard gold solution was drawn off into a beaker and diluted to the required volume. To this was added the necessary amount of a solution of pure and specially prepared potassium iodide, starch was added, and the freed iodine immediately treated with N/100 thio-sulphate solution, but only to the rose tint, so that, as in the actual analysis, there might be no decomposing action due to an excess of thio-sulphate upon the aurous salt.

The time was noted and the mixture allowed to stand until the iodine freed by the decomposition of the aurous iodide had brought the colour of the liquid to an ordinary starch blue. The data obtained in this manner are shown in the following table. The gold solution used contained 0.00048 grm. of metal to the cubic centimetre.

It may be seen from these results that the decomposition of the aurous iodide under the conditions is comparatively slow, although potassium iodide was present in large excess. In these experiments the colouration ran through various gradations from pink to blue, as the starch used, in common with most specimens, had suffered hydrolytic change, the pink colour indicating, of course, the incipient excess of iodine, and not under-titration as Rupp has stated (see Hale, *Am. Journ. Sci.*, 1902, [4], xiii., 390).

As I have previously shown, a complete determination by the method of Gooch and Morley can be easily accomplished in ten minutes; the maximum time actually necessary for the completion of the titration after the formation of the aurous iodide need not exceed four minutes. As can be seen from the experiments tabulated above, the minimum time required for the incipient decomposition of the aurous iodide was seventeen minutes. In no case did decomposition take place immediately, although potassium iodide was present in large excess. It is to be especially noted that these experiments begin where the analytical process ends, so that the probability of any iodine being freed by a too rapid decomposition is rendered yet more remote. The facts, then, afford absolutely no foundation

for the statement that the decomposition of aurous iodide is an inherent source of error in the method of Gooch and Morley.

Concerning the accuracy of the method proposed by Rupp it is unnecessary to speak further, since Rupp now disputes the desirability of estimating less than the milligram; but to the reduction of gold chloride by arsenious oxide, the reaction used by Rupp, it is necessary to recur. Rupp states that the process of reduction goes on in acid solution. As I said in a former paper, I have been unable to effect the precipitation of the gold when free acid is present, but after the addition of acid potassium carbonate reduction takes place. Rupp added to his solution of gold chloride containing hydrochloric acid 10 c.m. of nearly N/2 solution of arsenious oxide. It is to be supposed that this solution of arsenious oxide was made, as usual, by dissolving the oxide in acid potassium carbonate. The question arises as to whether Rupp did not have enough acid carbonate in his arsenic solution to neutralise the free acid. The fact that the gold was precipitated, and within ten or fifteen minutes, points strongly, according to my experience, to an alkaline condition of the solution. So, if to heat a solution of acid potassium carbonate upon the water bath, under the experimental conditions, brings about the formation of an iodine-binding carbonate, and is indeed an error as Rupp says, it would seem that Rupp makes that error. But was it an error? It has seemed worth while to investigate this point.

A N/10 arsenic solution was prepared, as usual, with the aid of 20 grms. of potassium acid carbonate to the litre. Twenty-two c.c. of this solution were drawn off and titrated with an approximately N/10 iodine solution in the usual manner. Four lots of this arsenic solution of 22 c.m. each were then carefully drawn off and heated upon the steam bath for thirty minutes, and when cool were titrated against the above-mentioned iodine solution. The volume of the solutions used in these experiments was in all cases approximately 75 c.c. The results obtained are given in the accompanying table:—

Standard As ₂ O ₃ taken.	Iodine used to titrate at once.	Iodine used to titrate after heating one-half hour on the water bath.
C. m. s.	C. m. s.	C. m. s.
22.0	22.08	22.10
22.0	22.07	22.08
22.0	22.08	22.09
22.0	22.07	22.08

These figures show conclusively that acid potassium carbonate in solution of the concentration used in these experiments, 0.44 gm. in a volume of 75 c.c., does not in thirty minutes heating upon the water bath undergo such change as to cause it to absorb an appreciable amount of iodine in the following titration. Just what the effect may have been in Rupp's experiments cannot, of course, be determined in the absence of knowledge in regard to the acidity of his gold solution, and the alkalinity of his arsenic solution.

In conclusion it is obvious that the criticisms made by Rupp are not warranted by the facts. While, as its author now concedes, the method proposed by Rupp is not to be considered of value for the determination of small amounts of gold, all the evidence goes to show that the process of Gooch and Morley is accurate, and in the hands of a skillful analyst, adapted to the estimation of minute quantities of gold.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

Ordinary Meeting, October 28, 1904.

Dr. R. T. GLAZEBROOK, F.R.S., President, in the Chair.

A PAPER ON "An Interference Apparatus for the Calibration of Extensometers," by Mr. JOHN MORROW and Mr. E. L. WATKIN, was read by Mr. MORROW.

The paper describes an apparatus for calibrating extensometers and similar instruments by comparison with the wave-length of sodium light. The apparatus is self-contained and easily made ready for use. It is capable of great accuracy, as it is unaffected by external disturbances, accidental displacements, or errors due to backlash in the apparatus itself. It consists essentially of two metal cylinders of equal diameter, with their axes in the same straight line, but with a small gap between their adjacent ends. The gap is increased or decreased by the movement of a lever actuating a screw, and the alteration in its amount is measured by the interference rings produced in an optical system situated inside the gap.

The extensometer is attached by its gauge-screws to the metal cylinders, and provides a second method of determining their relative axial displacement. The two sets of readings are taken simultaneously, and are compared. The points examined in any strain-meter are (a) the magnification constant, (b) the action at starting and reversing, and (c) the proportionality of reading to displacement. The experiments were made on an extensometer of the differential mirror type described by one of the authors.

Prof. S. P. THOMPSON said he was pleased to see that optical devices were being applied practically for measuring small lengths and for testing extensometers. It was a step in the direction of realising Maxwell's idea regarding the utilisation of the wave-length of light as a standard of length. He would like to know the "order" of the rings which were used in the experiments, and also if there was any difficulty due to the interference of the light emitted by the two sodium lines. It would be interesting to know how the authors had measured fractions of a ring, and what fraction of a ring it was possible to measure with accuracy.

The CHAIRMAN said the method employed was similar to that used by Fizeau; a method carried to perfection by Benoit in the measurement of the coefficient of expansion of small objects. The principle had been applied by the authors to practical mechanical problems.

Mr. MORROW, in reply to Prof. Thompson, said the rings used were near to the centre of the system. In fact, the two surfaces could be brought into contact and the experiments commenced from that position. Fractions of a ring

were estimated by eye, but there would be no difficulty in employing an eyepiece with a micrometer-scale. It was easy to estimate to one-tenth of a ring with the apparatus shown, but no mechanical device was accurate to anything like the same extent.

A paper on "A Sensitive Hygrometer," by Dr. W. M. THORNTON, was read by the Secretary.

The instrument is made by enclosing the cooled surface of a Regnault's hygrometer in a glass globe so that only the mass of vapour contained in the vessel is available for condensation. The cooled surface is made much smaller than usual—about 1 sq. c.m. The surface-density of the deposited moisture depends on the total quantity of water-vapour present. If this is more than a minimum to be determined later, it will be visible either by the loss of brightness by scattering, or by observing, as in the Dines hygrometer, the scattered light itself. Little is known as to the manner in which moisture is deposited on smooth cold surfaces. Dr. Park has shown that the thickness of the deposit is of the same order as that of the black spot in interference-films. The reflection of light from such a clear layer of uniform thickness backed by a bright surface is considered in the paper, and it is shown that the loss of light due to the thinnest possible films can be perceived. The opposite case to that of a smooth layer is that of clear spherical particles resting on the surface. This is also considered, and the surface-density to give a visible deposit is calculated. In connection with an interesting note was received from Lord Rayleigh in reply to an inquiry, in which he shows that the maximum brightness of a cloud is about 4×10^{-4} that of the sun. Comparing all values it is taken that 10^{-8} grms. per sq. c.m. can be detected by unaided vision with diffused light. The time taken for moisture to diffuse from a state of uniform distribution throughout the globe towards the centre is then calculated, and found to be less than ten minutes for a sphere of 20 c.m. diameter. In the experimental instrument an ether spray was directed on to the inner surface of a silver cap at the end of a steel tube. The latter is surrounded by a glass tube and air space, so that only the cap is exposed to the gas in the globe. Air dried in the usual way by passing slowly through tubes of sulphuric acid and phosphorus pentoxide was moist enough to dim the cap. For very dry gases it is suggested that liquid air might be used as a cooling agent. The paper is an attempt to make the somewhat neglected Regnault hygrometer an instrument of precision in the detection of small quantities of moisture. There is no other method known to the author by which this can be done, except in certain cases by the occurrence of chemical reaction causing a change of colour.

Dr. CHREE remarked that unless there were some means of recording the temperature of the metal on which the moisture was deposited, he did not see how absolute results could be obtained, and that unless numerical results were obtainable the sphere of usefulness of the instrument was likely to be limited. The ordinary methods of obtaining hygrometric results, viz., by wet and dry bulb hygrometers or by the hair hygrometer, left a good deal to be desired, especially at temperatures below $0^{\circ}\text{C}.$, so that there was an opening for an accurate hygrometer if not too complicated.

Prof. F. T. TROUTON said he had lately been making experiments bearing on the subject of the paper. He was engaged in determining the electrical resistance between electrodes fixed upon the surface of glass. At present he was investigating the resistance with the temperature of the glass well above the dew-point, and he found that it varied in a complicated manner with the time the current was allowed to pass. When the air was near the dew-point the variation of the resistance was altogether different in character from the variation when the air was far from saturation. The sudden variation in resistance when moisture was deposited upon the surface of the glass gave an accurate method of determining the dew-point.

The SECRETARY said the author had tried to make the instrument quantitative by determining the minimum

quantity of moisture which could be detected, and also by observing the time which elapsed before all the moisture was deposited.

A "Note on a Property of Lenses," by Dr. G. E. ALLAN, was read by the Secretary.

A well-known method of testing the concavity or convexity of a lens consists in holding the lens at arm's length, and, while looking through it, moving it from side to side or up and down, when the image in the convex lens is found to move in the opposite direction to that of the lens, whilst in the case of the concave lens it moves in the same direction. The above facts hold if, instead of the naked eye, we employ a microscope. If the division marks of a scale be looked at through a lens of considerable focal length, and the lens be at the same time moved across the field of view, it is seen that the motion of the lens is much greater than that of the image, and the disparity of the two motions is greater the nearer the lens is to the scale and the flatter the lens. It is shown that the focal length of a lens can be expressed as the product of the distance from the scale to the lens and the magnification, the magnification being defined as the ratio between the displacement of the lens and the displacement of the image. The results obtained by applying the method to the determination of the focal lengths of three lenses are given in the paper.

Mr. T. H. BLAKESLEY said he was aware of the method described by the author, which, with limitations, was accurate enough for the determination of focal lengths above 50 or 60 c.m. He pointed out that the formula given in the paper was not, in general, quite rigorous. The distance required was not from the scale to the lens, but from the scale to the first principal point. This difficulty could be easily overcome by making two experiments with different distances between the scale and the lens.

NOTICES OF BOOKS

Small Destructors for Institutional and Trade Waste. By W. FRANCIS GOODRICH, Assoc. Inst. Mech. Engineers, &c. With twenty-eight illustrations. London: Archibald Constable and Co., Ltd. 1904.

DESTRUCTORS for waste products of all kinds are coming more and more into vogue, and while those for civic use are multiplying rapidly there is also a growing demand for the smaller prototype—the destructor for dealing with institutional and trade refuse. These small destructors have not been discussed in the various books which have already appeared on refuse disposal; hence the present work.

This volume is intended for the use of architects, medical superintendents, and large manufacturers, and all who are concerned in the sanitary disposal of the waste produced in hospitals, infirmaries, asylums, convalescent homes, hotels, &c., where the available waste may be turned to profitable account for power production.

The book consists of six chapters, the first being introductory. In Chapter III. institutional destructors are described and illustrated, and Chapter IV. deals with portable destructors. Chapter V. is devoted to the American practice and the special features of the American designs, while in Chapter VI. the author discusses the disposal of trade refuse and its application to the production of steam power. The book is well printed and illustrated, and will no doubt be of considerable service to those in whose interests it is written.

We regret to point out that there is no index, though this loss is in part made up for by the table of contents.

The Electric Furnace. By HENRI MOISSAN. Authorised Translation by VICTOR LENHER, Ph.D., University of Wisconsin. Easton, Pa.: The Chemical Publishing Company. 1904.

The original French edition of this valuable work has been

already reviewed at length in the *CHEMICAL NEWS*, and we have but little to add to our previous remarks.

Since the publication of the French edition there has been a great development of certain industries in connection with the electric furnace, such as the preparation of calcium carbide, chromium, ferro-silicon, ferro-chromium, and ferro-titanium; while Mr. F. N. Acheson, in following up his discovery of the crystalline silicide of carbon, has been able to realise the industrial preparation of graphite.

The translator expresses his deep obligation to M. Moissan for the additional matter in manuscript, which is included in this translation, thereby bringing the work up to date.

The book is divided into four chapters. In the first the different forms of electric furnaces are described. Chapter II. contains the study of three forms of carbon—amorphous carbon, graphite, and diamond.

The third chapter gives the preparation of a number of elements by means of the electric furnace, and the fourth contains researches on a number of new binary compounds, the carbides, silicides, borides, phosphides, arsenides, and sulphides; while general conclusions complete the work.

It is a common fault in French books to be without an index; we are sorry the translator has not seen his way to prepare one for this English edition, which suffers from the omission. Apart from this we have no fault to find with the book.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade, unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxiv., No. 15, October 10, 1904.

The Transition Temperatures of Steels.—Georges Charpy and Louis Grenet.—The transition temperatures of certain carbon steels have lately been determined by studying the variation with temperature of their electric resistance, thermo-electric power, and rate of expansion or contraction. Transition temperatures obtained by the electric resistance method and by dilatometry agree within the limits of experimental error.

Percentage of carbon.	Transition temperature.			
	Electric resistance method.		By contraction.	
	Beginning	End.	Beginning	End.
0.82	730	760	735	745
1.06	730	760	740	750
1.15	739	739	735	740
1.38	750	750	735	755

Results obtained by thermo-electric and dilatation methods do not show much agreement, except in the case of the softest steels.

Substitution Derivatives of Phenyl diazoaminebenzene.—Leo Vignon and M. Simonet.—When certain substituted anilines react upon diphenylamine, substituted derivatives of phenyl diazoaminebenzene are obtained. The method of preparation is as follows:—The amines are diazotised as hydrochlorides, then treated with diphenylamine in alcoholic solution in the presence of carbonate of soda. The temperature is kept between 4° and 5°. The diazoamine formed is precipitated with water and excess of ice, and extracted with ether. The ether is dried over solid K_2CO_3 and evaporated, leaving behind the phenyl diazoaminebenzene derivative. In this way *o*-, *m*-, and *p*-nitro-, $[NO_2C_6H_4 \cdot N \cdot N \cdot C_6H_5]_2$, *o*-, *m*-, and *p*-chloro- and bromo-, *p*-iodo-, and methoxyphenyl diazoaminebenzene have been prepared; di- and trichloro- and bromo-derivatives have also been obtained. All these substances have the general properties of diazo-derivatives.

Bulletin de la Société Chimique de Paris.

Series 3, Vol. xxxi., No. 4.

Action of Carbonic Acid on Aqueous Solutions of Aniline in the presence of Nitrites.—Louis Meunier.—Already noticed.

Bromopivalic Acid and its Derivatives.—E. E. Blaise and L. Marcilly.—The authors have succeeded in preparing bromopivalic acid indirectly by treating oxypivalic acid with pentabromide of phosphorus. To 2 molecules of pentabromide of phosphorus they added, a little at a time, 1 molecule of oxypivalic acid; hydrobromic acid is given off, and the mass gradually becomes liquefied. It was heated on the water-bath to complete the reaction and to drive off a portion of the hydrobromic acid, which was formed according to the equation—

The liquefied mass was poured into water and partially neutralised with carbonate of sodium, still leaving some free hydrobromic acid. Exhaust three times with a large volume of ether; this solution is then dried, filtered, and evaporated. The residue consists of an oil which crystallises in a few days when kept protected from moisture. This product was distilled at 143–145° under 33 m.m., and it crystallised on cooling. It is very soluble in alcohol, ether, and most of the solvents. By etherification this bromopivalic acid gives bromopivalate of ethyl, identical with that obtained direct from the action of pentabromide of phosphorus on oxypivalate of ethyl. Several other derivatives are described, such as phospho di-oxypivalic acid, phospho di-oxypivalate of potassium, &c.

The β-Aldehyde Ethers.—E. E. Blaise and L. Marcilly.—The condensation of formate of ethyl with the ethers of the fatty acids cannot be effected except when the α-carbon atom has 2 atoms of hydrogen; thus the method cannot lead to the formation of β-aldehyde acid with a true aldehydic function. On the other hand, the authors have attempted to obtain these compounds by the careful oxidation of the α-dialcylhydracrylic acids, and their examination is a matter of great interest particularly as regards the possible parallelism of their properties with those of the β-ketonic ethers. The result of their research is to show the very great analogy between the β-aldehydic ethers and the β-ketonic ethers.

Acetones with an Acetylenic Function. New Method for the Synthesis of Pyrazols.—Charles Moreau and Maurice Brachin.—Already noticed.

Bismuthoprotocatechuic Acid.—Paul Thibault.—The author has prepared a well-crystallised bismuthoprotocatechuic acid having the formula $\text{C}_7\text{H}_5\text{O}_5\text{Bi}$, by the direct treatment of protocatechuic acid with pure hydrated oxide of bismuth; he has also obtained a few other derivatives of this acid, its sodium, potassium, and ammonium salts and its anilide. The preparation of these compounds has enabled him to determine the formula which should be given to this compound.

An Isomer of Borneol, Camphenolic Alcohol, and some Camphenolic Derivatives.—A. Béhal.—Camphenolic alcohol was prepared by mixing camphenolate of ethyl in a flask with half its weight of absolute alcohol; a vertical condenser is fitted and the sodium added all at once. The reaction is very lively. If a little sodium remains, add absolute alcohol until it has all disappeared. At this moment add, gradually, 50 grms. of water and heat to boiling for a quarter of an hour. Distil off the bulk of the alcohol on a salt bath, then continue the distillation with a current of steam so long as any oil remains on the surface. Exhaust the distillate with ether and dry over sulphate of sodium. Distil the ether, and rectify the residue at the ordinary pressure. The product is obtained

pure the first time. The cooled alkaline residue, treated with ice and acidulated with dilute hydrochloric acid, gives inactive camphenolic acid in a pure state. The author then describes the preparation and properties of several camphenolic derivatives.

Action of Laccase on Gaiacol.—Gabriel Bertrand.—Already noticed.

Stimulating or Paralysing Influences acting on Manganese regarded as an Oxygen Carrier.—A. Trillat.—Already noticed.

Production and Distribution of some Organic Substances in the Mandarin Orange Tree.—Eug. Charabot and G. Laloue.—From a number of experiments tried and fully described in this paper the authors have drawn the following conclusions:—The volatile acidity in the mandarin orange tree gets less from the leaf to the wood. In the same organ it is greater when this latter is young than when its development is more advanced. But in absolute value the amount of volatile acid is greater in an old leaf than in a young one, which shows that it is formed at a greater rate than it disappears.

MISCELLANEOUS.

Historical Medical Exhibition—Postponement.—Mr. Wellcome writes to say that the response to the announcement of the proposed Historical Medical Exhibition has been beyond his expectations, and this, together with the many valuable suggestions received from leading members of the profession and the trade, at home and abroad, has prompted him to considerably widen its scope. The extent of the work involved renders it impossible to fix a definite date for the exhibition until a later period, announcement of which will be duly made. Although in one sense, he regrets this delay, it will, on the other hand, enable him to make the exhibit more comprehensive and complete, and to include many objects of exceptional interest that have been promised from different quarters of the globe.

Society of Arts.—The Society of Arts will commence its fourth half-century on the 16th, when Sir William Abney, as Chairman of the Society's Council, will open the 151st Session with an address. The subjects on which papers will be read at the meetings before Christmas include British Trade, Canals, the St. Louis Exhibition, Patent Law, Burma, and Street Architecture. There will also be a course of lectures on wind instruments, with musical illustrations.

Royal Institution.—A Christmas Course of Lectures (adapted to a Juvenile Auditory) will be delivered by Mr. Henry Cunynghame, C.B., on "Ancient and Modern Methods of Measuring Time" (Experimentally Illustrated). The dates of the Lectures are December 27, 29, and 31, 1904; January 3, 5, and 7, 1905.

Examination of Liquid Crystals by means of Electrical Cataphoresis.—G. v. Bredig and G. v. Schukowsky.—If the liquids to which Lehmann has given the name liquid crystals are actually suspension or emulsion mixtures, as Tammann and G. Quincke suppose, they would, like these suspensions in nearly all cases, be cleared and separated by cataphoresis, i.e., the migration of the suspended particles in the electric current. The authors have applied this method of examination to five different turbid, double refracting liquids, obtaining their current either (1) from an accumulator battery of 72 volts or (2) from the secondary coil of a large inductor with mercury interrupter, and have found that generally no clearing of the liquid occurs. Thus the result of the electrical examination of liquid crystals does not confirm the view that they are emulsions or suspensions, but shows that probably they are definite chemical individuals possessing specific optical properties.—*Berichte*, xxxvii., No. 13.

Awards at the St. Louis Exhibition.—Messrs. Boake, Roberts, and Co. have received a Grand Prize, Two Gold Medals, and one Silver Medal, for their award at the St. Louis Exhibition. They exhibited Sulphurous Acid, Sulphites of Sodium, Potassium, Calcium, and other bases, in addition to their liquid SO₂ in syphons for college and lecture use. They also exhibited Phosphoric Acid, special Phosphates for pharmaceutical purposes, Hydrofluoric Acid, Metallic Fluorides, and Caramels and Colourings for all purposes.

The London Essence Company have forwarded us a copy of No. 4 of their half yearly reports. This number contains the results of their investigations on the high boiling constituent common to oils of lemon and limes; the research has resulted in the discovery of a new sesquiterpene, probably of the type of the olefinic sesquiterpene, and has also resulted in showing that terpineol is a constituent of lime oil. There are also a number of other interesting notes on essences, oils, &c., that will well repay reading through.

Messrs. F. E. Becker and Co. (W. and J. George, Ltd., successors) have just issued a new Illustrated and Descriptive Catalogue of Physical Apparatus, &c., manufactured by them. This is the largest and best English catalogue of its kind printed, and comprises some 630 pages and over 4000 illustrations; herein will be found all the newest up to date apparatus with all the latest improvements as manufactured at their works, while all obsolete apparatus has been omitted. The whole catalogue is arranged in a very clear manner under a number of principal headings, such as Magnetism, Heat, Sound, Light, Mechanics, Electricity, Pneumatics, Meteorology, X-ray Apparatus, &c., and a good index is provided; in fact, everything possible has been done to make this as perfect a guide as possible to users of apparatus in the subjects touched upon.

Royal Institution.—A General Monthly Meeting of the Members of the Royal Institution was held on the 7th inst. Sir James Crichton-Browne, Treasurer and Vice-President, in the Chair. H.H. The Raj Rana Bhawani Singh Bahadur of Jhalawar, Mr. J. Jennings, and Mr. E. J. Preston were elected Members. It was announced that the Institution had received a bequest of £100 under the will of the late Miss Harriet Jane Moore. The special thanks of the Members were returned to Dr. Ludwig Mond for his donation of £755 for the purpose of erecting a lift from the basement to the second floor of the Institution, and any surplus after the completion of the work to go to the Research Fund. During the recess the entrances and exits of the Lecture Room of the Royal Institution have been materially improved by the erection of two covered-in iron staircases and the widening of the doorways, and the ceiling has been considerably raised.

MEETINGS FOR THE WEEK.

WEDNESDAY, 16th.—Microscopical, 8. "Theories of Microscopic Vision" (a Vindication of the Abb's Theory), by A. E. Conrady.

Society of Arts, 8. (First Ordinary Meeting). Inaugural Address of the 151st Session, by Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., Vice-President and Chairman of the Council.

Chemical, 5.30. "Isomerism of the Amidines of the Naphthalene Series," by R. Meldola and J. H. Lane. "Theory of the Production of Mercurous Nitrite and of its Conversion into various Mercury Nitrates," by P. C. Ray. "Amidechlorides," by G. D. Lander. "New Synthesis of Isocaproaldehyde and some Derivatives," by D. T. Jones and G. Tattersall. "Influence of Substitution in the Nucleus on the Rate of Oxidation of the Side chain—II. Oxidation of the Halogen Derivatives of Toluene," by J. B. Cohen and J. Miller. "The Halogen Derivatives of Naphthacenequinone," by S. S. Pickles and C. Weizmann. "Constitution of Pyrazolidone Derivatives," by B. Prentice.

A Selection from MACMILLAN & CO.'S BOOKS FOR STUDENTS OF CHEMISTRY.

SECOND EDITION NOW READY.

THE PRINCIPLES OF INORGANIC CHEMISTRY. By WILHELM OSTWALD.

Translated with the Author's sanction by ALEX. FINDLAY,
M.A., Ph.D., D.Sc.
With 126 Figures in the Text. 8vo. 18s. net.

THIRD EDITION Entirely re-written and Enlarged. CHEMICAL TECHNOLOGY AND ANALYSIS OF OILS, FATS, AND WAXES.

By Dr. J. LEWKOWITSCCH, M.A., F.I.C., &c.
With 88 Illustrations and numerous Tables. Medium 8vo. 61s. top.
36s. net
NATURE.—"The standard English book of reference on the subject."

SECOND EDITION. TABLES FOR QUALITATIVE CHEMICAL ANALYSIS.

Arranged for the Use of Students.
By A. LIVERSIDGE, M.A., LL.D., F.R.S., Hon. F.R.S.E.;
Associate of the Royal School of Mines, London; Professor of
Chemistry in the University of Sydney.

. These Tables make a new departure in Qualitative Analysis, viz., by applying Quantitative methods to Qualitative Analysis. Special attention is paid to the reactions of the Rare Elements and to many common carbon compounds not usually included in such works.

FRACTIONAL DISTILLATION. By
SYDNEY YOUNG, D.Sc., F.R.S., Professor of Chemistry in University College, Bristol, With 72 Illustrations. Crown 8vo, 8s. 6d.

AN INTRODUCTION to the STUDY of
CHEMISTRY. By Prof. W. H. PERKIN, JR., Ph.D., F.R.S.,

VOL. XC., No. 2347.

THE USE OF SULPHATE OF HYDRAZINE IN GASOMETRIC ANALYSIS.

By J. DE GIRARD and A. DE SAPORTA.

GASOMETRIC analysis has the advantage of enabling us to make a certain number of the usual determinations with the aid of simple and commonly used apparatus with an accuracy quite sufficient for practical purposes. We thought it would be of advantage to extend the number of these determinations by taking advantage of the reducing powers of sulphate of hydrazine, and the regular disengagement of nitrogen which it effects in the cold with certain salts.

M. Purgotti (*Bull. Soc. Chim.*, Series 3, vol. xviii., p. 953) has already used sulphate of hydrazine for the estimation of salts of copper, but we have already pointed out that the following equation that he uses to show the reaction is incorrect, if not incomplete:—

Actually, when we mix a solution of sulphate of hydrazine at 3 per cent, with a solution of sulphate of copper at 3.5 per cent, we obtain a crystalline blue compound, very slightly soluble, which separates out readily. This is a double sulphate of copper and hydrazine, $\text{SO}_4\text{Cu} \cdot \text{SO}_4\text{H}_2\text{N}_2\text{H}_4$. The previous addition of a concentrated solution of chloride of sodium does not prevent the formation of this salt, neither does cold affect its formation, but it is destroyed immediately, with the formation of cuprous oxide and the evolution of nitrogen, on the addition of soda-lye to the solution. Thus the intervention of sea salt is of no use, and, on the other hand, the presence of soda is indispensable for the reaction to take place in the cold; that is to say, under the conditions necessary for carrying out volumetric analyses. The reaction corresponds exactly with the following equation:—

so that 4 molecules of crystallised sulphate of copper weighing 998 set free 1 molecule of nitrogen weighing 28.

The operation succeeds very well with Trubert's calimeter, which can be easily obtained, and which we need not describe here.

The solution containing the salt of copper to be estimated is introduced into the apparatus with the solution of sulphate of hydrazine, and the flask is filled up to the gauge mark with soda-lye at 36° . It is best to react with small portions of soda on the mixture, and to surround the flask with cold water to prevent any increase of temperature. With 2 grms. of sulphate, dissolved in 30 to 50 c.c. of water, treated with 12 to 15 c.c. of a 3 per cent solution of sulphate of hydrazine, and about 20 c.c. of soda-lye, the latter being added drop by drop, we obtain an evolution of about 50 c.c. of gas, variable with the pressure and more especially with the temperature. Under the same conditions of temperature and pressure 0.214 gm. of chloride of ammonium treated with hypobromite ought to give the same volume of nitrogen,—

as is proved by experiment.

We have also observed (Second Supplement of Wurtz, No. 45, p. 250) the reduction of Fehling's solution by sulphate of hydrazine.

We thought we might apply this chemical reaction to the gasometric estimation of glucose, but we found that in this

case sulphate of hydrazine does not give off nitrogen in the cold, even in the presence of a large excess of caustic soda. On the other hand, if we apply heat the reduction becomes more advanced, and it is metallic copper that separates out.

Nevertheless, we are still able to apply the use of sulphate of hydrazine to the gasometric estimation of glucose. For this purpose we commence by reacting under the ordinary conditions of concentration, with a measured volume of the sugar solution on an excess of Pasteur's solution kept for some time at the boiling point. The boiling solution is thrown on to a filter, the cuprous oxide formed is washed with warm water, and re-dissolved in a few drops of a mixture of dilute nitric and sulphuric acids in boiling water. Thus we get back to the previous case (estimation of sulphate of copper). We may here remark that it is advisable to partially saturate the cupric liquor with an alkali, before acting on it in the cold with the sulphate of hydrazine and the soda.

We give the following results as an example; they were obtained at a temperature of about 20° and a pressure of 670 m.m.:—

0.200 gm. of glucose gave	..	40 c.c. nitrogen
0.300 " " "	..	60 " "
0.400 " " "	..	80 " "

Ten c.c. of grape-sugar syrup, treated with acetate of lead and sulphate of sodium, and diluted to 1 litre, giving 5.95 grms. of sugar by direct estimation with Fehling's solution (M. Bonnaux's method), gave 6.10 grms. of sugar by the gasometric method on two successive samples.

Although taking a little longer than Fehling's direct estimation, this method enables us to do away with the uncertainties of the final point of the reaction, and the personal errors which vary with the sensitiveness of the eye of the operator.

We can also employ sulphate of hydrazine for other gasometric estimations. We will only refer here to its direct action on nitrite of sodium. Five c.c. of a solution of hydrazine at 3 per cent, treated with 10 c.c. of a solution of nitrite of sodium at 3 per cent, gives off 29.5 c.c. of nitrogen in the cold, exactly the same volume as 5 c.c. of the same solution of sulphate of hydrazine decomposed by hypobromite of sodium, which corresponds to the equation, $2\text{NO}_2\text{Na} + \text{SO}_4\text{H}_2\text{N}_2\text{H}_4 = \text{N}_2 + \text{SO}_3\text{Na}_2 + 2\text{NOH} + 2\text{H}_2\text{O}$.

Thus hyponitrous acid is formed, which remains in solution and is decomposed when we raise the solution to boiling point, giving off protoxide of nitrogen.

Further, it is easy to prove directly the presence of this acid, for, if inversely, we treat nitrite of sodium with an excess of sulphate of hydrazine, the solution gives a yellowish-white precipitate with nitrate of silver. This precipitate when drained, detonates violently if heated on a strip of platinum-foil; it is therefore composed of hyponitrite of silver.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 15.

Action of Carbonic Acid on Phenylbromide of Magnesium.—G. Schreter.—The reaction of carbonic acid on phenylbromide of magnesium is fairly complex. Starting with 40 grms. of bromobenzene we obtain 1 gm. of diphenyl, only 2 grms. of benzoic acid, 2.5 grms. of benzophenone, 7 grms. of triphenylcarbinol, 1.5 grms. of a compound fusible at 165° , which seems to be a molecular compound of benzophenone and triphenylcarbinol. Further, there is a little phenol formed, through the action of the atmospheric oxygen. These reactions may be represented by the following equations:—

The relative quantities of these products vary with the experimental conditions.—*Berichte*, vol. xxxvi., p. 3005.

THE DETERMINATION OF LIME.

The gravimetric determination of calcium is almost invariably made by precipitating as oxalate and weighing as oxide or sulphate. The general practice is to precipitate from a slightly ammoniacal solution, which contains some ammonium chloride, by means of ammonium oxalate; and when pure solutions only are in question the results obtained are quite accurate, *e.g.* :—

CaO present. Grm.	CaO found. Grm.
0.0066	0.0067
0.0132	0.0131
0.0333	0.0332
0.0667	0.0670
0.1667	0.1669
0.3330	0.3345

If the lime is strongly ignited and weighed quickly the results agree very well with those obtained after moistening with sulphuric acid, re-igniting to low redness, re-weighing, and calculating from CaSO_4 to CaO. The ignited precipitate should be white, but if the ammonium oxalate contains manganese or the added ammonium chloride iron—as in my experience they may—the precipitates are slightly pink (and may even be brown), and to a corresponding extent heavier than they should be.

Lime is precipitated by little more than the theoretical amount of ammonium oxalate, but it is in no way detrimental to add large excesses, *e.g.* :—

Amount of ammonium oxalate (c.c.)	15	50	100
CaO precipitated (grm.)	0.1996	0.1996	0.1995

Lime may also be precipitated as oxalate from solutions containing free oxalic, citric, salicylic, or acetic acid, *e.g.*, when precipitated from a solution containing :—

20 per cent free acetic acid the CaO weighed	0.1992	grm.
8 " " " " " "	0.1985	"
2 " " " " " "	0.1990	"
0 " " " " " "	0.1993	"

In the absence of ammonium salts the precipitated calcium oxalate, even after boiling for some time, filters rather badly. The addition of acetic acid effects an improvement in this respect. In the presence of ammonium salts, however, the precipitates, if heated awhile, become distinctly crystalline, and filter and wash easily. The presence of ammonium salts does not otherwise affect the determination, *e.g.* :—

In the absence of ammonium salts the CaO weighed	Grm.
" presence of 20 grms. chloride	0.1996
" " " " nitrate	0.2000
" " " " acetate	0.2006
" " " " "	0.1990

If lime is being precipitated from solutions which contain other metallic salts it can generally be obtained in a purer form if an excess of free acetic acid is added than if the solution is kept neutral or made slightly alkaline, as many metallic oxides, with which calcium is commonly associated, are precipitated in alkaline solutions. The washing of the precipitate in the former case is then made with water containing about 1 per cent each of ammonium oxalate and acetic acid. The extent to which other metals may be present under these conditions has been studied experimentally. Unless otherwise stated, the following tests were carried out in solutions containing 8 per cent of free (B.P.) acetic acid and 2 decigrams. of lime.

When from 20 to 30 grms. of sodium or potassium chloride was present in the solution the results were from 1 to 3 per cent too high; the correct result can, of course, be obtained by re-precipitating.

Zinc, barium, and lead readily form insoluble compounds with ammonium oxalate; their presence would therefore always interfere with the determination of lime.

Nickel and cobalt are precipitated by ammonium oxalate after standing for some time, and must therefore always

be separated if more than comparatively small amounts are present.

Copper to the extent of a decigram. contaminates the lime only to a very slight extent or not at all, *e.g.*, 0.1987 grm. of CaO instead of 0.2000.

Aluminium (decigram.).—The solution should be neutralised with ammonia until a faint precipitate of aluminium hydrate appears; this should be cleared up entirely with a very slight excess of hydrochloric acid, and then 8 or 10 per cent of free acetic acid should be added. The slight excess of free hydrochloric acid must be destroyed by adding ammonium oxalate until the lime begins to be precipitated, and then in addition as much as will precipitate all the lime present. The CaO obtained under these conditions weighed 0.2000 grm., and was quite free from alumina.

Uranium shows no tendency to be precipitated with the lime, *e.g.*, 0.2002 grm. of CaO was obtained.

Arsenic also shows no tendency to be precipitated with the lime.

Molybdenum shows a slight tendency to be co-precipitated, but when a decigram. of this metal was present the CaO weighed only 0.2020.

Iron in the ferric state is not precipitated along with the lime to any serious extent; for example, 0.2031 grm. of CaO instead of 0.2000 grm. was obtained from a solution containing 0.1430 grm. of ferric oxide. Lime may also be precipitated directly from a solution of basic slag, according to both Immendorf and Reitmar, if the free hydrochloric acid in which it has been dissolved is neutralised with potassium or ammonium oxalate. The precipitated lime will be free from phosphoric acid, and contain traces only of other bases unless much manganese happens to be present.

Calcium phosphate is easily soluble in dilute acetic acid, and therefore the presence of phosphoric acid can interfere only to a very slight extent, *e.g.*, when precipitated from a solution containing 1 grm. of microcosmic salt, the CaO weighed 0.2008 instead of 0.2000 grm., and contained 0.0012 grm. of P_2O_5 .

Manganese, even when present in small amounts, is partly carried down with the lime. The separation of manganese from lime by means of bromine and ammonia is not exact, but it is often resorted to on account of its convenience. The manganese is more accurately separated by precipitating from a hot ammoniacal solution by means of sulphuretted hydrogen. There seems some uncertainty as to whether the separation by means of persulphates is accurate. It is often quite as convenient to neglect the presence of manganese until after the ignition, then to dissolve the impure lime in hydrochloric acid, evaporate the solution with sulphuric acid to fumes, and then determine the amount of the associated manganese by the bismuthate process, *e.g.* :—

0.2210 = weight of impure CaO.

0.0220 = weight of Mn_2O_4 determined by the bismuthate process.

0.1990 grm. CaO instead of 0.2000.

Chromium as a salt of chromic oxide exhibits no tendency to go down with the lime, but it prevents the precipitation of calcium oxalate to a serious extent however long the solution may be boiled. The results are, however, much better if a very large excess of ammonium oxalate is added, and the solution allowed to stand for several days. Chromium as chromic acid, however, exerts no influence on the precipitation except that, as it is reduced by oxalic acid in hot solutions, the entire precipitation must be carried out in the cold. The results are accurate.

Magnesia occurs more frequently than any other base in solutions from which lime has to be precipitated. The accurate precipitation of small amounts of lime from solutions containing comparatively large amounts of magnesia is a question of commercial importance, and makers of magnesia bricks, &c., for metallurgical purposes have often

good reason for complaining of the quantity of lime the analyst reports having found in their products. It is important to bear in mind that calcium oxalate is soluble in magnesium chloride, and that magnesium oxalate is only sparingly soluble in water. It is necessary, therefore, in order to ensure a complete precipitation of the lime, to add at least as much ammonium oxalate in excess as will transform all the magnesia into magnesium oxalate (i.e., about four times the weight of the magnesia present), and then to make the solution so dilute that no magnesium oxalate can crystallise out. The presence of free ammonia and warming of the solution favour the co-precipitation of magnesia; the presence of ammonium chloride retards it. The following method gives quite satisfactory results:—

Neutralise the solution, dilute it so that each 100 c.c. contains not more than 0.15 grm. of magnesia, add at least 10 grms. of ammonium chloride, and then acetic acid equal to 2 or 3 per cent of the volume of the solution, and, lastly, an amount of ammonium oxalate equal to four times the weight of the magnesia present, and as much besides as will precipitate the lime. Larger amounts of ammonium oxalate or ammonium chloride are without influence. The solution should be well stirred, but not heated, and allowed to stand for one hour or more before filtering. The following results were obtained with solutions which in each case contained 0.625 grm. of magnesia.

CaO added.	CaO found.
0.0133	0.0145
0.0133	0.0135
0.0333	0.0325
0.0660	0.0670

The first of these tests was allowed to stand twenty-four hours, the others stood only from one to two hours.

A.W.B.

AN IMPROVED FORM OF CONDENSER.

By HERBERT EDWARD BURGESS.

It will be admitted that a double surface condenser must necessarily be more efficient and economical than the ordinary Liebig or Graham type, but most condensers made on the double surface condensing system have serious disadvantages which militate to a great extent their usefulness and general adoption in laboratories. A few may be mentioned:—

1. Difficulty in cleaning.
2. In getting a uniform flow of water over the whole surface, which leads to considerable chances of breaking where the hot vapour meets the cold part of condenser.
3. When the outer condensing water is enclosed it entails the making of several sealed glass joints which are very liable to fracture, add to the cost of apparatus, and when broken cannot be repaired.

FIG. 1.

- A Cold water inlet to
- B Inner cold tube.
- C Outlet from ditto through
- D Rubber joint to
- E Outer cold-water jacket.
- F Outlet from ditto.

- F Condenser tube.
- G Outlet from ditto.
- H Ground joint.
- I and K Rubber joints.

4. They are all designed to be used in a vertical position, or if used in a horizontal position a small portion of the distillate will remain between the two condensing spaces.

To overcome some of these disadvantages I suggested to Messrs. C. E. Müller, Orme, and Co., Ltd., to make for me the condenser as shown in the illustration, and which I have found on the severest tests to be very efficient; it was primarily intended for distillations with direct steam, but answers equally well for ordinary distillations or under reduced pressure. It can be easily cleansed by removing the inner condensing tube; in case of breakage any part may be easily renewed at very small cost, or, in fact, can be replaced from the stores of any ordinary laboratory, or it may be used in any position with or without vacuum; it takes less than one-third of bench room than an ordinary Liebig type condenser.

FIG. 2.

For distillations under reduced pressure, where fractions have to be separated, the fractionating end as shown in Fig. 2 will be found extremely useful and convenient.

Laboratories, London Essence Co.,
George Street, Camberwell, S.E.

Gummed Reagent Labels.—Messrs. F. E. Becker and Co. (W. and J. George, Ltd., Successors), of 23–27, Hutton Wall, E.C., have just issued a new assortment of gummed reagent labels that is rather out of the ordinary. The design of book has for its object the combination of “maximum usefulness with minimum waste.” The novelty consists in arranging the type and boundary lines of uniform size, so that parts of different labels can be joined together. In this way any possible—or, for that matter, impossible—combination of metal and acid radical can be built up; if the cutting and joining is done neatly it need scarcely be visible. The advantage of such an arrangement is obvious. The type is large and plain, and the book includes small labels for Pure, Commercial, Normal, Decinormal, &c.; also a number of large ones for drawers and shelves. They appear to be well gummed, and will be very useful in technical and college laboratories.

PROCEEDINGS OF SOCIETIES.

THE ROYAL SOCIETY.

THE Council of the Royal Society have made the following awards of Medals for this year :—

The Copley Medal to Sir William Crookes, F.R.S., for his long-continued researches in spectroscopic chemistry, on electrical and mechanical phenomena in highly rarefied gases, on radio-active phenomena, and other subjects.

The Rumford Medal to Professor Ernest Rutherford, F.R.S., for his researches on radio-activity, particularly for his discovery of the existence and properties of the gaseous emanations from radio-active bodies.

A Royal Medal to Professor William Burnside, F.R.S., for his researches in mathematics, particularly in the theory of groups.

A Royal Medal to Colonel David Bruce, R.A.M.C., F.R.S., for his researches in the pathology of Malta fever, nagana, and sleeping sickness, and especially for his discoveries as regards the exact causes of these diseases.

The Davy Medal to Professor William Henry Perkin, jun., F.R.S., for his discoveries in organic chemistry.

The Darwin Medal to Mr. William Bateson, F.R.S., for his contributions to the theory of organic evolution by his researches on variation and heredity.

The Sylvester Medal to Professor Georg Cantor, for his researches in the theories of aggregates and of sets of points of the arithmetic continuum, of transfinite numbers, and Fourier's series.

The Hughes Medal to Sir Joseph Wilson Swan, F.R.S., for his invention of the electric incandescent lamp and various improvements in the practical applications of electricity.

CHEMICAL SOCIETY.

The following are abstracts of papers received during the vacation and published or passed for publication in the *Transactions* :—

137. "The Action of Chromyl Chloride on Stilbene, Styrene, and Phenanthrene." By GEORGE GERALD HENDERSON and THOMAS GRAY.

Each of the hydrocarbons, stilbene, styrene, and phenanthrene, when treated with chromyl chloride in carbon disulphide solution, yields a solid brown additive compound. These solids are decomposed by water, and oxidation products of the hydrocarbons are liberated. Stilbene is oxidised to benzil, and, with partial decomposition, to benzophenone and benzaldehyde. Styrene yields benzaldehyde as the chief product, together with a trace of phenylacetaldehyde and a small amount of a chlorinated compound. The sole product obtained from phenanthrene was phenanthraquinone.

138. "The Stereoisomeric Tetramethyl Methylglucosides and Tetramethyl Glucose." By THOMAS PURDIE and JAMES COLQUHOUN IRVINE.

The pentamethyl glucose (m. p. 42–43°) obtained from tetramethylglucose, either by the silver oxide method of alkylation or by the action of methyl alcohol containing hydrogen chloride (*Trans.*, 1903, lxxxiii., 1035), proves to be tetramethyl- β -methylglucoside; the stereoisomeric liquid α -glucoside is produced simultaneously, but in much smaller proportion. The β -glucoside is characterised by its levorotatory power, its more rapid hydrolysis by hydrochloric acid, and its susceptibility to the hydrolytic action of emulsin.

In aqueous solution, tetramethyl glucose, like glucose itself, exhibits phenomena of mutarotation. The α -form (m. p. 88–89°); $[\alpha]_D^{20} + 100.8^\circ$ is obtained by repeated crystallisation of the crude aldose from petroleum; the β -form (Tanret's γ -form), or at least a mixture containing

a large excess of it ($[\alpha]_D^{20} 73.1^\circ$), is produced by heating the α -form above its melting-point. The modification, which is stable in solution ($[\alpha]_D^{20} 83.3^\circ$), is apparently a mixture of the two dynamic isomerides. In the solid state, the β -isomeride reverts to the α -form.

Mutarotation was also observed in benzene and carbon-tetrachloride, and therefore neither ionisation nor the formation of hydrates or compounds of the acetal class is essential for the occurrence of this phenomenon.

139. "The Alkylation of Galactose." By JAMES COLQUHOUN IRVINE and ADAM CAMERON.

The silver oxide method of alkylation, when applied to α -methylgalactoside, gives rise to tetramethyl α -methylgalactoside, a colourless, refractive liquid (b. p. 136–137°/11 m.m., $[\alpha]_D^{20}$ of the pure liquid is $+105.7^\circ$, and in aqueous solution $[\alpha]_D^{20}$ is $+143.4^\circ$). Hydrolysis with hot dilute hydrochloric acid leads to the production of tetramethyl galactose, a colourless refractive syrup (b. p. 172°/13 m.m.). After distillation, the alkylated sugar displays mutarotation, not only in water, but also in alcohol and benzene, the permanent values for these three solvents being $+109.5^\circ$, 62.6° , 90.0° respectively. In other respects, also, the behaviour of the compound supports the view that it has an oxidic structure.

When the substance is either heated with methyl alcohol and hydrochloric acid or treated with silver oxide and methyl iodide, the stereoisomeric tetramethyl α - and β -methylgalactosides are produced, the latter method giving a large excess of the β -compound, whilst the former yields a greater proportion of the α -isomeride. The crystalline β -form (m. p. 44–45°) is much more readily hydrolysed than its isomeride, either by dilute acids or by emulsin.

140. "A Method for the Rapid Ultimate Analysis of Certain Organic Compounds." By JOHN NORMAN COLLIE.

The method consists in burning the substance in a known volume of oxygen, noticing any change in the volume of the gas, and then, by absorbing the carbon diox. e' produced, data sufficient for the calculation of the per cent amounts of carbon and hydrogen are obtained.

Only those substances can be estimated which are not appreciably volatile in a vacuum, and which contain only carbon and hydrogen or carbon, hydrogen, and oxygen. The time required for an analysis is only about an hour; the amount of substance used can be reduced to nearly one-tenth of that ordinarily employed, and as the measurements depend on volumes of gases the method is very accurate.

141. "The Comparative Nitrifying Power of Soils." By SYDNEY FRANCIS ASHEY.

The method devised for comparing quantitatively the power of cultivated soils to convert their ammonia into nitrites and nitrates has justified itself by :—

1. Yielding samples giving reasonably similar nitrifying power from different parts of the same field.
2. Causing equal seedlings from the same sample to show similar nitrifying power.
3. Minimising loss of nitrogen by volatilisation of ammonia and denitrification during incubation.
4. Limiting the incubation period to about thirty days.
5. Showing a nitrifying power of the soils tested which corresponds with their fertility as gauged from manuring and crop production.

142. "The Action of Organic Bases on Olefinic Ketonic Compounds." By SIEGFRIED RUHEMANN and EDWIN ROY WATSON.

Benzylidenecacetylacetone readily unites with *m*-toluidine, *p*-toluidine, *m*-chloroaniline, *p*-chloroaniline, β -naphthylamine, and piperidine, but it does not combine with *o*-toluidine, α -naphthylamine, or tetrahydroquinoline.

Piperidinobenzylidenecacetylacetone, —

is stable in a dry atmosphere, but in the presence of moisture it gradually decomposes with the formation of enzyldenebisacetylacetone, benzaldehyde, and piperidine.

The production of benzylidenesacetylacetone and similar compounds from benzaldehyde and ketonic compounds is therefore preceded by the formation of additive compounds of piperidine with olefinic ketonic compounds. This view is supported by the fact that benzylidenesacetylacetone, which combines with piperidine, also condenses with acetylacetone in the presence of the base to form benzylidenesacetylacetone, whilst no such reaction takes place if tetrahydroquinoline, which does not form an additive compound with the olefinic ketone, is used instead of piperidine.

With phenylhydrazine, dibenzylidenesacetylacetone forms the phenylhydrazone, $(C_6H_5.CH:CH)_2C:N:NH.C_6H_5$, and not an additive compound; with ammonia, it yields a mixture of substances from which has been isolated the compound having the formula $C_{34}H_{35}N_3$.

Benzylidenesacetylacetone dibromide, when condensed with ammonia, yields aminobenzylidenesacetylacetone, $C_6H_5.C(NH_2):CH.CO.C_6H_5$; it therefore follows that the corresponding compound obtained by Wieland (*Ber.*, 1894, xxvii., 1150) from ammonia and *p*-nitrobenzylidenesacetylacetone dibromide is also unimolecular.

143. "Halides of the Acridines and Naphthacridines." By ALFRED SENIER and PERCY CORLETT AUSTIN.

The halogens combine directly with the acridines, forming a series of well-defined crystalline compounds, which are sparingly soluble in organic media, and are obtained by mixing the reagents either alone or in a suitable solvent. The products, which have characteristic colours, are unstable, especially in presence of water. The fluorescence, when in solution, which is so marked a character of acridines generally, and which depends on the presence of the acridine "fluorophore," is absent, except in three instances.

That these compounds are not substitution derivatives follows from their instability, the small number of halogen atoms which they contain, and the fact that no acridone is formed when they are treated with water or alkalis. They are therefore additive compounds, namely, halides. Moreover, the addition takes place in the acridine ring, for, were it otherwise, monadic atoms would be added only in pairs, which, however, is not the case, and a higher number would combine owing to the disruption of the centric benzene linkings.

Adopting this view, two formulæ are possible for the dihalides. The first, which is of the type of the dihydrides or dihydroacridines (Bernthsen and Bender, *Ber.*, 1883, xviii., 1802), is suggested for the non-fluorescent dihalides, and the second corresponding with the acridinium salts, alkylhalides, and alkylhydroxides, is employed for the dihalides which exhibit fluorescence. In accordance with the foregoing hypothesis, the tetrahalides should have formulæ of the former non-fluorescent type, and acridine tetrabromide, the only tetrahalide described, was found to be non-fluorescent.

Those compounds which contain one halogen atom combined with one and three molecular proportions of base respectively are regarded as being products intermediate between the bases and the dihalides, in the one case, and the dihalides and tetrahalides in the other, and to these products dimolecular formulæ are assigned.

144. "Reactions Involving the Addition of Hydrogen Cyanide to Carbon Compounds. Part II. Cyanohydrins regarded as Complex Acids." By ARTHUR LAPWORTH.

Under certain conditions, an aqueous solution of potassium cyanide readily dissolves benzaldehyde and camphorquinone. From the resulting liquids, crystalline additive products having approximately the compositions $C_7H_6O.KCN.2\frac{1}{2}H_2O$ and $C_{10}H_{14}O_2.KCN.3H_2O$ have been isolated. These substances behave as salts of the corresponding cyanohydrins, which are probably much feeble acids than hydrocyanic acid itself.

145. "Reactions Involving the Addition of Hydrogen Cyanide to Carbon Compounds. Part III. Action of

Potassium Cyanide on Mesityl Oxide." By ARTHUR LAPWORTH.

It was shown that when mesityl oxide is heated with potassium cyanide dissolved in dilute alcohol, hydrogen cyanide is first assumed at the ethylenic carbon linking, and that the potassium hydroxide which is simultaneously produced converts the product into mesitonic acid; more prolonged heating results in the formation of mesitylic acid, which necessitates the addition of a second molecule of hydrogen cyanide in this case to the carbonyl group, and the subsequent hydrolysis of the product.

146. "6-Aminocoumarin." By GILBERT THOMAS MORGAN and FRANCES MARY GORE MICKLETHWAIT.

6-Aminocoumarin, although resembling the naphthylamines in containing two unsaturated rings, nevertheless behaves towards diazonium salts like a para-substituted benzenoid amine, giving rise to stable diazoamino-derivatives.

This base and its mono- and di-alkylated compounds and the corresponding hydrazine and diazocyanide are all coloured substances, whereas the salts of these bases, the acyl derivatives of the primary and secondary amines, the nitrosamines of the monoalkyl derivatives, the diazonium salts of the parent base and its quaternary bromides and iodides are colourless.

147. "Studies in Asymmetric Synthesis. I. Reduction of Menthyl Benzoylformate. II. Action of Magnesium Alkyl Haloids on Menthyl Benzoylformate." By ALEXANDER MCKENZIE.

When *l*-menthyl *dl*-mandelate is hydrolysed by an amount of potassium hydroxide insufficient for complete hydrolysis, an optically active mandelic acid is invariably obtained from the potassium salt thus formed. The mixture of esters remaining after this partial hydrolysis, when completely hydrolysed, yields mandelic acid which is either optically active or inactive, according to the experimental conditions. In the complete hydrolysis, by potassium hydroxide, of a mixture of *l*-menthyl *d*-mandelate and *l*-menthyl *l*-mandelate containing an excess of either of those esters, racemisation phenomena are observed.

On reducing menthyl benzoylformate to menthyl mandelate and hydrolysing the latter, the mandelic acid obtained was inactive. But it does not follow from this result that equal amounts of *l*-menthyl *d*-mandelate and *l*-menthyl *l*-mandelate were present in the product obtained by the reduction of menthyl benzoylformate, since, even if unequal amounts have been present, the mandelic acid obtained might still have been inactive owing to the racemising effect of the hydrolysing alkali.

Further investigation showed that a slight excess of *l*-menthyl *l*-mandelate was present in the reduction product, which, however, on hydrolysis, yielded *r*-mandelic acid.

When menthyl benzoylformate, $PhCO.CO_2.C_{10}H_{19}$, is acted on by magnesium methyl iodide and the magnesium addition compound then decomposed by water and dilute acid, a new asymmetric carbon atom is produced. In this instance, no racemising effects are observed on hydrolysing the product with alkali, since an optically active potassium salt is present in solution after the complete removal of the *l*-menthol, and this salt yields an optically active phenylmethylglycollic acid, $CMePh(OH).CO_2H$. An optically active phenylethylglycollic acid was also obtained in a similar manner.

That the optical activity exhibited by phenylmethylglycollic and phenylethylglycollic acids, prepared by Grignard's reaction, was actually due to their asymmetric synthesis was shown by preparing diphenylglycollic (benzilic) acid from menthyl benzoylformate and magnesium phenyl bromide. In this case, where a new asymmetric carbon atom was not produced, the resulting acid was inactive.

148. "The Relation of Position Isomerism to Optical Activity. II. The Rotation of the Menthyl Esters of the

Isomeric Chlorobromobenzoic Acids." By JULIUS BEREND COHEN and HENRY STANLEY RAPER.

The authors have extended the research of Briggs and Cohen on the relation of position isomerism to the rotations of the menthyl esters of the six dichlorobenzoic acids (*Trans.*, 1903, lxxxiii., 1213) by preparing and examining the menthyl esters of the ten isomeric chlorobromobenzoic acids.

The molecular rotations of these esters agree in a very satisfactory way with those of the dichlorobenzoic esters.

The greatest effect in decreasing the rotation is produced when the halogen enters the ortho-position with respect to the ester group; the least when both halogens are in the meta-position. The mean order of magnitude, beginning with the ester of lowest rotation, is as follows:—

2 : 6 ; 2 : 3 ; 2 : 5 ; 2 : 4 ; 3 : 4 ; 3 : 5 ; phenyl,

which is precisely the order of rotation of the dichlorobenzoic esters.

When the chlorine is nearer to the ester group than the bromine, a greater depression in the rotation is produced than by the reverse arrangement. Moreover, when the chlorine occupies the ortho-position to the ester group, the rotation is lower than that of the corresponding dichlorobenzoic ester. The general effect of bromine is to influence the rotation less than the chlorine—a result which seems to follow from the effect of the monohalogen esters.

The great contrast afforded by the two symmetrical compounds of both series, namely, the 3 : 5- and 2 : 6-esters, is not a little remarkable, and these isomerides may be regarded as the first and last terms of a series in which the 2 : 6-compounds have a high melting-point and low rotation, whilst the 3 : 5-isomerides have a low melting-point, low density, and high rotation.

149. "The Relation of Position Isomerism to Optical Activity. III. The Rotation of the Menthyl Esters of the Isomeric Iodobenzoic Acids." By JULIUS BEREND COHEN and HENRY STANLEY RAPER.

In a former communication (Cohen and Briggs, *Trans.*, 1903, lxxxiii., 1216), the rotations of the menthyl esters of the three monochlorobenzoic acids were given and compared with the constants obtained for the monobromobenzoic esters by Tschugaeff. The authors have now determined the constants for the menthyl esters of the three iodobenzoic acids.

150. "The Chlorination of the Trichlorotoluenes in presence of the Aluminium-mercury Couple. The Constitution of the Tetrachlorotoluenes." (Part V.). By JULIUS BEREND COHEN and HENRY DRYSDALE DAKIN.

In previous papers (Part III., *Trans.*, 1901, lxxix., 1111; Part IV., *Trans.*, 1902, lxxxi., 1325), the authors have traced the progressive chlorination of toluene as far as the formation of the trichlorotoluenes. The products formed on introducing a fourth chlorine atom into each of the six trichlorotoluenes have now been investigated.

On chlorinating 3 : 4 : 5-trichlorotoluene at 0°, the chlorine enters the side-chain instead of the nucleus.

Although there appears to be no general law determining the position of the fourth entrant chlorine atom, yet there exists a remarkable agreement between the positions taken by the entrant chlorine atoms and nitro-groups when the first two chlorine atoms have been introduced into either benzene or toluene. Whatever the ultimate explanation may be, it is clear that after the first two chlorine atoms have been introduced into benzene and toluene the special rules which usually govern substitution are wholly or in part set aside in favour of a more general law which includes both the substituent chlorine atom and also the nitro-group.

151. "The Chemical Dynamics of the Reactions between Sodium Thiosulphate and Organic Halogen Compounds. Part I. Alkyl Haloids." By ARTHUR SLATOR.

The reactions between sodium thiosulphate and methyl, ethyl, and ethylene haloids have been investigated in dilute solution, and shown to be in most cases bimolecular, thus,

$\text{CR}_3\text{I} + \text{S}_2\text{O}_3^{--} = \text{CR}_3\text{S}_2\text{O}_3^{--} + \text{I}^+$. Water was used as a solvent whenever possible, but in a few cases a mixture of this liquid and alcohol had to be employed.

The rate of reaction is approximately trebled for a rise of 10°. The velocity-coefficients may be used to compare the reactivities of these haloids. With two of the compounds ($\text{C}_2\text{H}_5\text{I}$, $\text{C}_2\text{H}_5\text{BrCl}$) the velocity of the reaction with excess of thiosulphate is independent of this excess, and the reaction is therefore unimolecular. To explain this result, it is suggested that the haloids are capable of existing in two tautomeric forms, and that the measurable reaction represents the change of one form into the other.

152. "Note on Methyl Fluoride." By JOHN NORMAN COLLIE.

Methyl fluoride under 2 m.m. pressure, when contained in a vacuum tube having aluminium electrodes and subjected to the spark from an induction coil, gives a bluish green colour. The spectrum, however, rapidly changes, and the characteristic lines of hydrogen make their appearance. When sparked under the ordinary pressure, the gas is almost immediately decomposed in the following manner:— $4\text{CH}_3\text{F} = 4\text{C} + 2\text{H}_2 + 2\text{H}_2\text{F}_2$. In glass tubes, a secondary change occurs; the silicon fluoride formed by the action of the hydrogen fluoride on the glass is reduced by the hydrogen, and silicon is deposited:— $\text{SiF}_4 + 2\text{H}_2 = 2\text{H}_2\text{F}_2 + \text{Si}$.

153. "Acetylenic Ketones." By EDWIN ROY WATSON. The action of various bases on bromobenzylideneacetophenone, $\text{C}_6\text{H}_5\text{CBr}:\text{CH}:\text{CO}:\text{C}_6\text{H}_5$, has been investigated in the hope that a molecule of hydrogen bromide might thereby be eliminated from this compound (compare Ruhemann and Watson, *Trans.*, 1904, lxxxv., 457). The action of solid powdered potash gives rise to phenylacetylene, potassium benzoate, and potassium bromide.

The action of alcoholic ammonia gives rise to aminobenzylideneacetophenone, $\text{C}_6\text{H}_5\text{C}(\text{NH}_2):\text{CH}:\text{CO}:\text{C}_6\text{H}_5$, and by the action of piperidine two compounds—dipiperidinobenzylideneacetophenone and piperidinobenzylideneacetophenone—are produced. Strong bases replace the bromine atom in bromobenzylideneacetophenone by an amino- or substituted amino-group.

Phenylpropyl chloride reacts readily with anisole to produce the expected acetylenic ketone, methoxybenzylphenylacetylene. On substituting benzene for anisole the simple reaction no longer occurs, but several substances are produced, including a hydrocarbon having the empirical formula $\text{C}_{14}\text{H}_{12}$.

Methoxybenzylphenylacetylene and piperidine yield piperidinomethoxybenzylstyrene,—

whilst the action of hydroxylamine gives rise to 1-phenyl-3-methoxyphenylisooxazole.

Benzoylphenylacetylene yields the phenylhydrazone, $\text{C}_6\text{H}_5\text{C}:\text{C}(\text{C}_6\text{H}_5):\text{N}:\text{NH}:\text{C}_6\text{H}_5$, and the anilino benzoylstyrene, $\text{C}_6\text{H}_5\text{C}(\text{NH}:\text{C}_6\text{H}_5):\text{CH}:\text{CO}:\text{C}_6\text{H}_5$, when treated with phenylhydrazine and aniline respectively.

154. "Note on Bergamot Oil and Other Oils of the Citrus Series." By HERBERT EDWARD BURGESS and THEODORE HENRY PAGE.

Acetic acid, octylene, pinene, camphene, and limene have been identified as constituents of a specimen of pure oil of bergamot. The pungency of the first fractions of this oil on distillation is accounted for by the acetic acid, which was also found in smaller quantities in lemon oil, and is probably present in the other oils of this series.

The octylene found in lemon oil was identical with that in bergamot oil, for both gave butyric acid on oxidation with potassium permanganate. It is probably a normal constituent of the citrus oils. A second phenylurethane isolated from the terpineol fraction of distilled oil of limes melts at 132°, is more soluble than that obtained from ordinary terpineol, crystallises in tufts of needles, and gives on hydrolysis an oil with an intense odour of distilled oil of limes.

155. "The Resolution of Externally Compensated Dihydro- α -methylindole." By WILLIAM JACKSON POPE and GEORGE CLARKE, jun.

On crystallising externally compensated dihydro- α -methylindole with *d*-bromocamphorsulphonic acid, *l*-dihydro- α -methylindole *d*-bromocamphorsulphonate, $C_{10}H_{11}N \cdot C_{10}H_{11}Br \cdot SO_3H$, first separates, and on purification crystallises in needles (m. p. $179.5-180.5^\circ$; $[M]_D + 27.8^\circ$ in aqueous solution). With caustic soda it yields *l*-dihydro- α -methylindole, which is obtained as a colourless oil (b. p. $22.8-22.9^\circ$; $[a]_D - 13.61^\circ$ in a 1 dm. tube). The base is dextrorotatory in ethyl alcohol and benzene solutions, but levorotatory in ethereal solution.

A more sparingly soluble dihydro- α -methylindole *d*-bromocamphorsulphonate (m. p. $124-125^\circ$) accompanies the above salt, but, although it has the low molecular rotatory power of $[M]_D + 24.62^\circ$ in aqueous solution, corresponding with the presence of a basic ion of $[M]_D - 30^\circ$, this salt yields inactive base and inactive benzoyl and acetyl derivatives.

On adding caustic soda to the final mother-liquors obtained during the resolution, impure *d*-dihydro- α -methylindole separates, but was not obtained free from the *l*-isomeride; its benzoyl and acetyl derivatives were, however, prepared in a state of purity, and have properties corresponding with those of their optical antipodes.

156. "The Vapour Pressures of Sulphuric Acid Solutions and the Molecular Condition of Sulphuric Acid in Concentrated Solution." By BRYCE CHUDLEIGH BURT.

The vapour pressures of sulphuric acid solutions of various concentrations (from 25 to 95 per cent H_2SO_4) have been determined by an ebullioscopic method. The values so obtained lie on smooth curves when plotted against temperature and concentration. The molecular weight has been calculated from Raoult's corrected formula:—

$$m = M \cdot \frac{g}{G} \cdot \frac{p'}{p - p'}$$

where m = molecular weight of solute; M = molecular weight of solvent in the gaseous state; g = weight of solute; G = weight of solvent; p = vapour pressure of pure solvent; p' = vapour pressure of solution. The values for m obtained vary over very wide limits, increasing with rise of temperature and decreasing with increase in concentration. The different values do not lie on smooth curves when plotted against temperature and concentration.

These abnormalities can only be explained by supposing that combination occurs between the solvent and solute with the formation of complex molecules, the formation of such complexes being favoured by an increase in concentration, but not by a rise in temperature.

157. "Reactions Involving the Addition of Hydrogen Cyanide to Carbon Compounds. Part IV. Addition of Hydrogen Cyanide to Benzylidenacetophenone." By ARCHIE CECIL OSBORN HANN and ARTHUR LAPWORTH.

The addition of hydrogen cyanide to benzylidenacetophenone takes place only in presence of a considerable quantity of potassium cyanide, and the failure of Rupe and Schneide (*Ber.*, 1895, xxviii., 957) to bring about the addition process is thus explained. When the solution is but feebly alkaline, the product is β -benzoyl- α -phenylpropionitrile, $CHPh(CN) \cdot CH_2 \cdot C(=O)Ph$, but in presence of alkali the latter condenses with unaltered benzylidenacetophenone to yield the compound $C_{17}H_{15}ON$, which Rupe and Schneide obtained in small quantities.

The *orime*, $CHPh(CO_2H) \cdot CH_2 \cdot C(=O)Ph \cdot N \cdot OH$, when warmed with sulphuric acid, undergoes the Beckmann change, yielding phenylsuccinic acid and aniline, by which reaction the constitution of the ketonic acid is established.

By means of the quinine salt, β -benzoyl- α -phenylpropionic acid was resolved into its optical isomerides; the *laevo*-acid, melting at $176-178^\circ$ in 6 per cent ethyl acetate solution, had $[a]_D - 157.57^\circ$, whilst the *dextro*-acid had $[a]_D + 157.3^\circ$.

158. "The Bromination of Silver Cyanate." By GEORGE DEAN.

Silver cyanate, when treated with an equivalent weight of bromine in a sealed tube, yielded a yellow product, $AgCNBr$. The substance, which did not darken on exposure to light, gave off bromine when heated above 70° . At $300-400^\circ$, the bromine evolved from the substance was accompanied by a thick sublimate of cyanogen bromide. The substance dissociated under $10-20$ m.m. pressure. Water acts on the compound, yielding silver bromide, cyanuric acid, carbon dioxide, and nitrogen; hydrochloric acid gives rise to a mixture of silver chloride and bromide, whilst cyanogen chloride, bromine, and oxygen are eliminated. The compound oxidises alcohol to acetaldehyde. When the cyanate was brominated at a lower temperature, much more halogen was absorbed; the product, however, was readily decomposed in a current of air, leaving the less brominated compound.

159. "The Decomposition of Chloral Hydrate by Sodium Hydroxide and by certain Salts." By EMIL ALPHONSE WERNER.

It is shown that the quantity of chloral hydrate decomposed by sodium hydroxide is a function of the temperature, for one molecular proportion of this alkali is capable of decomposing from one to four molecular proportions of the hydrate with production of chloroform, sodium formate, and free formic acid. Sodium acetate and similar salts are also capable of decomposing the hydrate with the production of formic acid. Water and dilute acids do not decompose chloral hydrate in this manner.

Two alternative theories are put forward to explain the decomposition. Firstly, it is assumed that a sodium derivative, $CCl_3 \cdot CH(ONa) \cdot OH$, formed on adding the alkali or salt, is immediately decomposed into chloroform and sodium formate. The decomposition of relatively large proportions of the hydrate by sodium hydroxide is easily explained in this way.

Secondly, the production of "nascent" carbon monoxide, $>C:O$, as distinct from C_2O , is suggested, this hypothetical substance then uniting with water to give formic acid.

160. "Contributions to the History of Glyoxylic Acid." By HEINRICH DEBUS.

Two views still prevail with regard to the formula of glyoxylic acid; some chemists represent its composition by the formula $C_2H_2O_3 \cdot H_2O$, whilst others prefer the expression $C_2H_4O_4$. The author, after discussing the arguments in favour of each formula, comes to the conclusion that the formula $C_2H_2O_3 \cdot H_2O$ is more in harmony with the properties of glyoxylic acid than the other.

Some basic salts of glyoxylic acid are described which readily decompose into the corresponding glycolates and oxalates.

161. "The Colouring Matters of the Stilbene Group." (1). By ARTHUR GEORGE GREEN.

The colouring matters of the stilbene class cannot have the simple structure assigned to them either by O. Fischer and Hepp, or by Bender and Schultz. Apart from the general improbability that substances so constituted would have dyeing properties, the following facts indicate that they have a more complex structure:—

1. Colouring matters can be obtained from *p*-nitro-toluenesulphonic acid by condensation with alkalis under suitable conditions, which, although having the general characteristics of Curcume S or Direct Yellow, contain aldehydic groups in addition to the stilbene group.

2. Stilbene dyes of mixed type can be obtained by condensing dinitrostilbenedisulphonic acid with aromatic amines under the influence of alkalis.

3. Curcume or Direct Yellow does not give rise on oxidation to dinitrostilbenedisulphonic acid, but furnishes a yellow dye of greener shade, which is very similar to the first product of the alkaline reduction of dinitrostilbenedisulphonic acid.

The author has endeavoured to elucidate the constitution

of the crimson-red compound, which invariably precedes the formation of the stilbene colouring matter, and is evidently the first phase of the condensation. The fact that this substance, on oxidation with hypochlorite, gives dinitrostilbenedisulphonic acid (Green and Wahl, *Ber.*, 1897, xxx., 3097), and is again regenerated from this acid on reduction, supported by a study of its phenyl ester and the analogous chloro-compound (compare next abstract), leads to the view that the crimson-red intermediate compound is a nitroso-stilbene or stilbene nitrolic acid having a quinonoid structure in alkaline solution.

102. "The Colouring Matters of the Stilbene Group." (II.). By ARTHUR GEORGE GREEN, FRED SCHOLEFIELD, and FRED MARSDEN.

In order to elucidate the constitution of the crimson-red compound obtained on heating *p*-nitrotoluenesulphonic acid with caustic alkalis, and which forms the first phase of the stilbene condensation, the authors have investigated the behaviour of the corresponding phenyl ester, $C_6H_3(CH_3)(SO_3C_6H_5)(NO_2)[1:2:4]$, and chloro-compound, $C_6H_3(CH_3)Cl(NO_2)[1:2:4]$. The first of these compounds, in alcoholic solution, gives, on adding caustic soda, an intense bright blue coloration even in the cold; the second gives a reddish-violet coloration at 20–30°.

It being found impracticable to isolate these coloured substances on account of their extreme instability, their behaviour on oxidation was studied. They are rapidly decolorised both by sodium hypochlorite and by air, and give rise to derivatives of dinitrostilbene. From the phenyl ester, a mixture of the *trans*- and *cis*-phenyl dinitrostilbenedisulphonates was produced. The same two compounds were also obtained from Green and Wahl's dinitrostilbenedisulphonic acid by conversion into the sulphonic chloride, and treatment with sodium phenoxide. This fact serves to confirm the constitution assigned above, and also shows that the dinitrostilbenedisulphonic acid, and probably also the crimson-red intermediate compound and the stilbene colouring matters generally, must consist of mixtures of *trans*- and *cis*-isomerides.

The reddish-violet intermediate compound from *o*-chloro-*p*-nitrotoluene, on oxidation with air or sodium hypochlorite, yielded a mixture of *trans*- and *cis*-dichlorodinitrostilbenes; the yield of the two isomerides being nearly theoretical, the formation of a third substance is excluded, and a simple connection between the coloured intermediate compound and the respective dinitrostilbene derivative is indicated. This is further supported by the fact that these dinitrostilbene derivatives are readily re-converted by alkaline reducing agents, such as phenylhydrazine and caustic soda, into the blue and reddish-violet compounds from which they are obtained. The authors are thus led to assign to the latter the structure of nitrostilbenes or stilbene nitrolic acids.

103. "Researches on Chromorganic Acids; the Behaviour of [Chromic Hydroxide towards Oxalic Acid and certain other Organic Acids." By EMIL ALPHONSE WERNER.

An aqueous solution of oxalic acid, when saturated with chromic hydroxide, yields a deep purplish-red liquid, which, on evaporation, leaves a dark green residue, appearing almost black by reflected light. This compound has the properties of a true chromoxalic acid, $H_7Cr_4(C_2O_4)_6(OH)_{5.4}H_2O$, and yields an ammonium salt, $(NH_4)_3Cr_4(C_2O_4)_6(OH)_{5.2}H_2O$.

Whilst thoroughly washed chromic hydroxide is readily dissolved by oxalic acid in the proportion required by the formula $Cr_2(C_2O_4)_3$, this is not the case with other related organic acids. Under similar conditions, malonic acid dissolves approximately 50 per cent of the calculated amount, whereas, with succinic acid, the interaction is appreciable. A chromomalonic acid, having the formula $H_7Cr_4(C_3H_2O_4)_6(OH)_5.6H_2O$, analogous to the chromoxalic acid, was obtained, and also a chromomalonnate, $K_2Cr_2(C_7H_2O_4)_4.10H_2O$, forming dark purplish-red crystals, the analogue of Croft's red chromoxalate.

The proportion of chromic hydroxide dissolved by malic, tartaric, tricarballic, citric, glycollic, and lactic acids

under the conditions described is relatively small, varying from a minimum of 12 per cent (malic acid) to a maximum of 27 per cent (lactic acid). In all these cases, chromorganic acids are produced, having, in general, properties resembling those of chromoxalic acid. With tartaric acid, a saline chromium tartrate, $Cr_2(C_4H_4O_6)_3$, is also formed. When the red salt, $K_2Cr_2(C_2O_4)_4.10H_2O$, is boiled in aqueous solution with 2 molecules of potassium oxalate, the blue chromoxalate, $K_6Cr_2(C_2O_4)_6.6H_2O$, is produced; a similar result is brought about by other salts, such as potassium acetate, malonate, or succinate, and so far no chromium compound containing two different acid groups has been obtained.

A well-defined potassium boro-oxalate,—

which is readily obtained by boiling solutions of potassium metaborate and oxalic acid or boric acid and potassium-hydrogen oxalate, is described. A similar compound is not formed with malonic or succinic acid.

(To be continued.)

NOTICES OF BOOKS

Imperial Institute. Technical Reports and Scientific Papers. Edited by WYNDHAM R. DUNSTAN, M.A., F.R.S. With a Preface by the late Sir FREDERICK ABEL, Bart., K.C.B., F.R.S. London: Richard Clay and Sons. 1903. Pp. 236.

THE technical reports and scientific papers included in this volume are selected from among the more important of those which have emanated from the Scientific and Technical Department of the Imperial Institute since it was established on a definite footing in 1896. The department has been very widely used by India and the Colonies for the purpose of ascertaining, chiefly through chemical investigation in its laboratories, the composition of raw materials of all kinds.

In many cases the results of these investigations have suggested possible uses for the products, suggestions which in many cases have been put to practical tests by manufacturers.

The technical reports cover a variety of subjects, such as minerals, including coal, iron ores, mica, &c., fibres, essential and edible oils, and oil seeds, rubber and gutta-percha, gums and resins, medicinal plants and tobacco, tanning and dyeing materials, fodder, timber, &c. The scientific papers have been chiefly communicated to the Royal and Chemical Societies, and the principal papers are here reprinted from the *Transactions and Proceedings* of these Societies. The appendix contains a paper on "The Coal Resources of India," which embodies a report originally made by Prof. Dunstan to the Government of India in 1898. The volume is a valuable one, containing as it does a large amount of information of great importance to India and the Colonies.

Tables for Qualitative Chemical Analysis. Arranged for the Use of Students. By A. LIVERSIDGE, M.A., LL.D., F.R.S., Hon. F.R.S.E., Associate of the Royal School of Mines, London, Professor of Chemistry in the University of Sydney. Second Edition. London: Macmillan and Co. 1904.

In these tables the attempt has been made to combine the advantages of quantitative methods with the process of qualitative analysis. The course includes some original and exceedingly valuable methods of working. The student is required to use weighed and very small quantities of materials, to promote accuracy of work and to save time. The advantage of the use of "equivalent solutions" is insisted upon. Much stress is laid upon the value of preliminary dry tests for minerals and common substances. The student who has been well grounded in this branch of

analysis, if provided with a blowpipe, a candle, and a few accessories and reagents, is almost independent of a laboratory.

The book begins with the reactions of metals, then acids, alcohols, and their derivatives, carbohydrates, glucosides, aromatic compounds, and alkaloids. Then follows a very complete set of "Tables for Qualitative Chemical Analysis."

There is also an Appendix with Tables of Solubilities, Reagents in Equivalent Solutions, International Atomic Weights, Weights and Measures, and Formulæ of Reagents.

Altogether the book is a useful thoroughly workable textbook, and one that is likely to find considerable favour with teachers of chemistry.

There is a complete index, and the price is very reasonable.

Percentage Tables for Elementary Analysis. By LEO F. GUTTMANN, Ph.D., A.C.G.I., A.I.C. London and New York: Whittaker and Co. 1904.

The tables are for the rapid calculation of the percentage of carbon and hydrogen in a substance which, on combustion, yields carbon dioxide and water, and are calculated for O=16.00, C=12.00, and H=1.01. The method of interpolation for the fourth place of decimals is accurate. The headings of all the tables are printed in German, French, and English, and there is also included a table for the reduction of volumes of nitrogen to grammes.

CORRESPONDENCE.

RADIUM.

To the Editor of the Chemical News.

SIR,—While there is so much being said in all the chemical and scientific journals of Europe and America regarding radium, it may be interesting to the scientific world to know something of the history and discovery of the ores that have given the world a new theme in mining to talk about. Before going into details, it may be said that the home of radium is in the uranium mines of the La Sal mountains in Utah, and nowhere else in the world is that character of ore being produced in sufficient quantity to supply the demand.

Early in 1888 M. Charles Polias, a French professor residing in Denver, went into the La Sal country in search of uranium deposits, stating that the supply from the uranium mines in Germany was gradually decreasing, and that a new field must be found to supply the demand. Professor Polias located several promising deposits along Rock Creek and Sinbad Valley, and, gathering up a few samples, returned to Paris for the purpose of determining the value of the mineral. It was found to contain values enough to warrant further investigation, and in 1890 a French company began the erection of a uranium plant near the deposits. But when the plant was nearly ready for operation the mill buildings caught fire and were destroyed, thus ending the explorations of Professor Polias and the French company.

In the year 1900, S. F. Lockwood, a New York capitalist, and William Banta, a young metallurgical student, secured an option on the Welsh-Loffitt group of uranium mines near Richardson, also in the La Sal mountains, and began to investigate the ore. They were engaged for a full year in thoroughly analysing this ore for the rare metal, outside of the ordinary mineral values. The ore was found to contain seven different metals, in addition to gold, silver, and copper. It was by pure accident that the radium values were discovered. Now during all this time the French chemists were ignorant of the source of the ore from which

they had discovered their radium, and were relying on the pitchblende products of the Hungarian mines for their small and limited supply.

Messrs. Lockwood and Banta organised a company to develop the property, and are building a reduction plant at Niagara Falls, New York, which will soon be completed, and immediately begin experimental work upon the ore. When it is satisfactorily known that their Niagara plant is a success, and just what kind of machinery and chemicals are required to work the ores, they will build a plant on the Grand River, two miles from the deposits, and thoroughly and systematically work the property. Mr. Lockwood is very sanguine in his belief that they are now prepared to successfully carry out their work, and that within a very short time they will be able to show the scientific world something that is new to the mining industry in general, and America in particular.

When radium, as a commercial metal, was discovered by Professor and Madame Curie in Paris in 1898, its value was quoted at something like £1,000,000 per pound, and only a grm. of the metal was on the market. The present price is about £560,000 per pound, but Mr. Lockwood confidently states that they will be able to reduce the value of this precious metal to about £125,000 per pound. It requires 2000 tons of the ore to be reduced to produce one pound of the radium ore.

The vein in which the ore is found is a true fissure, fully 40 feet wide, in a white sandstone formation. It has been exposed for 3000 feet by cuts and shafts, so the company will experience no lack of ore.

Hoping that the above may be of some interest and value to your readers,—I am, &c.,

H. OTLEY BEYER.

University of Denver,
Denver, Colorado.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxiv., No. 16, October 17, 1904.

The Boiling-point Constants of Mixtures.—C. Marie.—Experiments upon the boiling-points of mixtures of alcohol and water, in which resorcin was dissolved, do not verify the formula theoretically calculated by Nernst,

$$\frac{1}{K_m} \left(\frac{1}{K_1} \frac{q}{100} + \frac{1}{K_2} \frac{100-q}{100} \right);$$
 where K_1 , K_2 represent the molecular elevation of the two solvents, q and $100-q$ their relative proportion by weight, and K_m the boiling-point constant of the mixture. With four different mixtures of alcohol and water—

K_m (observed)	10.36	12.13	15.99	22.05
K_m (calculated)	9.36	7.39	6.80	6.36

The author considers this divergence between observed and calculated results to be due to certain approximations made by Nernst in calculating his formula. Experiments were also made on mixtures of alcohol and water containing a solid soluble in one of the constituents, insoluble in the other, and partially soluble in the mixture. The addition of a solid—soluble in water, insoluble in alcohol—is found to lower the boiling-point of the mixture.

The Action of Magnesium Alkyl Compounds upon the Halogen Derivatives of Phosphorus, Arsenic, and Antimony.—N. Auger and M. Billy. —The object of these researches was to obtain mono- and di-alkyl derivatives of the metalloids of the trivalent group. The chloride of the metal was dissolved in anhydrous ether and cooled to a low temperature by means of solid carbon dioxide and

acetone. Magnesium ethyl (or methyl) bromide was then slowly added from a dropping funnel. Mono- and dialkyl derivatives were isolated from the products of the reaction. This treatment proved most successful in the case of antimony, a mono-ethyl iodide of which ($C_2H_5SbI_2$) was precipitated by means of excess of KI. This substance, when pure, consists of golden scales, which melt at 43° and are decomposed at 200° .

An Organic Persulphate.—R. Fosse and P. Bertrand.

—When dinaphthopyranol, $C_{10}H_6 \begin{smallmatrix} \text{CHOH} \\ \text{O} \end{smallmatrix} C_{10}H_6$, or the oxide of dinaphthopyryl, $(C_{10}H_6 \begin{smallmatrix} \text{CHO} \\ \text{O} \end{smallmatrix} C_{10}H_6)_2O$, is added to dilute sulphuric acid and gently heated, a blood-red solution is produced, which, when filtered and cooled, crystallises into a red mass. The pyranol has reacted with one molecule of acid, according to the equation—

This sulphate has oxidising properties; when treated with KI the red solution is decolourised and pyryl tri-iodide and bis-dinaphthopyryl are formed:—

It transforms alcohol into aldehyde:—

These reactions make it evident that the graphic formula must be that already given, viz.,—

The Constitution of the Rosaniline Salts, and the Mechanism of their Formation.—Jules Schmidlen.—In a previous paper the two phases accompanying the solution of rosaniline carbinol in dilute acetic acid were described. The author ascribes these two phases to the intermediate formation of the colourless tetraoxycyclohexane rosaniline, which is unstable in weak acids. Hence the secondary phase, by which—with the loss of four molecules of water—the hexahydrobenzene nucleus is converted into a quinone nucleus and fuchsin is formed. The cyclohexane derivative is, however, stable in strong acids. Hence, when excess of acid is added to fuchsin, the rosaniline trichloride first formed (being unstable in solution) takes up four molecules of water, and is converted into the colourless stable tri-acid salt of tetracyclohexane rosaniline. When the carbinol is dissolved in excess of acid, the tri-acid cyclohexane derivative is formed at once, no secondary phenomenon being observed.

Tetrahydride and Octohydride of Anthracene.—Marcel Godchot.—The tetrahydride, $C_{14}H_{14}$, forms colourless crystals, which melt at 89° and can be sublimed. It is soluble in boiling benzene, and the solution has a blue fluorescence. It easily loses four atoms of hydrogen. The octohydride, $C_{14}H_{18}$, crystallises in little transparent and colourless tables; it melts at 91° , and sublimes above its melting-point. It dissolves in warm alcohol, acetic acid, benzene and its homologues. Its solutions have a characteristic green fluorescence. It combines with picric acid to form a crystalline picrate. Treated with bromine, a dibromo-octohydride of anthracene ($C_{14}H_{16}Br_2$) and a dibromohexahydride of anthracene ($C_{14}H_{14}Br_2$) are simultaneously formed. When the octohydride is oxidised, two new substances are produced—a tetrahydroanthraquinone and a hexahydroketone of anthracene.

Berichte der Deutschen Chemischen Gesellschaft.

Vol. xxxvii., No. 14, 1904.

Origin of Fusel Oils.—O. Emmerling.—Repeated experiments performed by the author, using different yeasts and carbohydrates, prove that, so long as the material is perfectly pure, fusel oils are either not produced at all, or else in only very minute quantities. Hence the formation of fusel oils is due to the action of bacteria upon the carbohydrates. This has been conclusively proved by many experiments. The author has not succeeded in isolating these bacteria, though he has repeatedly met with the same forms in fermentations. The most suitable materials for the formation of fusel oils appear to be starch and saccharose, especially if they have not been subjected to hydrolysis. As by-products of the reaction hydrogen and carbon dioxide are formed and also butyric acid. Pentoses also appear to be capable of giving rise to fusel oils. The examination on a small scale of the fusel oils obtained showed the presence of propyl, butyl, and amyl alcohol, and traces of ethyl alcohol. The time in which fermentation is completed varies very considerably; usually all the fusel oil is formed in four weeks, sometimes much sooner. In a few cases, for some unexplained reason, no higher alcohols whatever are formed.

Action of Light on Triphenylmethyl.—M. Gomberg and L. H. Cone.—If 3 per cent solutions of the different analogues of triphenylmethyl are kept for some time in absence of air, their colour gradually disappears, and at the same time the dissolved substances lose their unsaturated character. This was supposed to be caused by some unknown agent which had an effect similar to that of small quantities of hydrochloric acid, which convert the triphenylmethyl into hexaphenyl ethane. The authors have now shown that the cause of this phenomenon is the action of light. The analogues are apparently much more sensitive to light than the triphenylmethyl itself, and almost always lose their colour in two months (except in the case of solutions of naphthylidiphenylmethyl), while triphenylmethyl itself can be kept in diffused daylight for more than a year without suffering any appreciable decomposition. A solution of triphenylmethyl in benzene rapidly fades in direct sunlight; three to four hours of bright sunlight being usually sufficient to completely decolourise a 15 per cent solution contained in a closed test-tube of 3 c.m. diameter. The reaction occurs still more quickly in carbon tetrachloride, but more slowly in carbon disulphide, probably because, in the latter case, the actinium rays are hindered by the intense red colour which the solution soon assumes. The weight of the decomposition product formed by the action of light on a benzene solution of triphenylmethyl amounts to about 105 per cent of the triphenylmethyl originally taken. About 65 per cent of the product is triphenylmethane, while the rest consists of products insoluble in ether (about 25 per cent) and a strongly aromatic smelling oil. The part insoluble in ether consists of at least two different substances—one unsaturated and melting at 237° , and the other saturated and melting at 194° . In carbon tetrachloride no triphenylmethane is formed, but about 50 per cent of an oil result besides a crystalline mixture not yet investigated. No hexaphenyl ethane is formed in either case. These facts seem to show that the benzene plays some part in the transposition, possibly that of a reducing agent. It is noteworthy that while Kahlbaum's triphenylmethane, when its solution in benzene is exposed to direct light, gave small quantities of an insoluble substance melting at 256° , a very carefully purified specimen of the same hydrocarbon, even after exposure to direct sunlight for two months, gave no traces whatever of this product.

New Method of converting Organic Acids into Esters.—A. Werner and W. Seybold.—By the action of dimethyl sulphate on aqueous solutions of the alkali salts of organic acids the methyl esters of the acids can be obtained. The yield is often exceptionally good. This method can be used to prepare those esters which cannot

be prepared by the ordinary esterification methods with alcohols, e.g., 2—4—6 tribrom benzoic acid ester. A small excess of normal caustic potash is added to 5 grms. of the carboxylic acid, and then shaken for some time with the amount of dimethyl sulphate calculated to two molecules. The temperature of the mixture rises to 30° or 40°, and the ester separates out. The reaction is completed in half an hour, and then the mixture is heated for half an hour on the water-bath, to decompose the excess of dimethyl sulphate. On cooling, the free acid is removed by excess of alkali, and the ester if solid is filtered off, washed, and dried, and if it is liquid the alkaline liquid is distilled in a current of steam, when the ester passes over.

Compounds of Unsaturated Ketones with Metallic Chlorides.—Arthur Rosenheim and Walter Levy.—In compounds of inorganic haloids with organic oxygenated substances mostly very simple stoichiometric relations occur. Thus pentavalent elements—e.g., antimony—form compounds of formula MeCl_5X ; quadrivalent, MeCl_4X ; trivalent, MeCl_3X . The power of forming such compounds belongs to almost all classes of oxygenated compounds. In investigating the influence of double bonds on the composition of the addition products of substances containing oxygen the authors have succeeded in confirming Bayer and Villiger's hypothesis, that the formation of coloured hydrochloric acid compounds of dibenzalacetone is to be ascribed to the carbonyl oxygen. The first experiments showed that one double bond in the molecule of organic compound alters the intensity of the reaction when addition compounds are formed. Thus cinnamic acid, aldehyde, and ester react much more energetically than saturated compounds. The composition of the molecular compounds in the two cases is quite analogous, but their stability is much greater in the case of unsaturated than saturated compounds. With more than one double bond the reaction proceeds much more slowly, the products are intensely coloured, and the composition does not generally correspond to the above formulae. All observations confirm Straus's results, i.e., that the added molecule in unsaturated ketones does not attach itself at the double carbon bonds, and thus is independent of the number of these double bonds: for all ketones with two, three, or four double bonds form addition products of perfectly analogous composition with the same number of metallic salt or acid molecules. The authors' experiments go to show that the tendency to form addition compounds in unsaturated as in saturated compounds is due to the oxygen they contain, and that this activity on the part of the oxygen is greatly increased by the presence of double bonds in the molecule.

The so-called Magnesium Peroxide.—Otto Ruff and Emil Geisel.—The preparation of magnesium peroxide from sodium peroxide and magnesium hydrate or basic magnesium carbonate gives a very impure product. The authors have now found that by using magnesium sulphate and 30 per cent hydrogen peroxide, to which caustic soda had been added (all liquids being cooled to 0°), they obtain a peroxide which, on analysis without being dried, shows a composition of 1 molecule of magnesium oxide to 0.67 atom peroxide oxygen. On drying the preparation gives up oxygen. At from 25° to 37° and ordinary pressure, after twenty-two days the proportion is 1 molecule MgO to 0.39 peroxide oxygen, and this remains practically constant. The composition of the preparation then corresponds to the formula $\text{MgO}_2 \cdot 3\text{MgO} \cdot \text{aq}$. In presence of the water liberation of oxygen proceeds more quickly.

Electrolytic Reduction of Aromatic Esters.—Carl Mettler.—Aromatic esters, when subjected to electrolysis under suitable conditions, take up hydrogen and pass into compounds which no longer possess the most characteristic property of esters, i.e., power of being saponified by alkalis. Thus, benzoic acid methyl ester exposed to the reducing action of a lead cathode in alcoholic sulphuric acid solution, on application of sufficient current is converted into a non-saponifiable compound of boiling point 165° to 195°. By repeated fractional distillation, or by the help of certain

reagents, this can be separated into two fractions, one boiling at 201° and exhibiting all the properties of benzoyl alcohol, with which compound it is identical, while the other boils at 168°, and is pure benzyl methyl ether. Similarly for benzoic acid ethyl ether. No doubt benzaldehyde alcoholate of formula $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{OR}$ is formed as an intermediate product, but it has not yet been isolated. The halogen benzoic acids are converted chiefly into halogen alkyl ether, some alcohol being also formed. By means of suitable oxidising agents these compounds can readily be oxidised to the corresponding halogen benzaldehydes, many of which are closely related to technically important dyes.

MEETINGS FOR THE WEEK.

WEDNESDAY, 23rd.—Society of Arts, 8. "The Systematic Promotion of British Trade," by Gen. H. Morgan.

HACKNEY INSTITUTE, DALSTON LANE, N.E.

The Governing Body require the services of an ASSISTANT LECTURER in the CHEMISTRY DEPARTMENT on two evenings per week. Fee, 15s. per evening (1 two and a-half hours). Application, with testimonials, to be sent to the SECRETARY, not later than NOVEMBER 30th, 1904.

CENTRAL TECHNICAL SCHOOLS FOR CORNWALL, TRURO.

The Committee requires an ANALYTICAL CHEMIST with a sound knowledge of Agriculture. Capable of teaching; and also to assist the Principal, Professor CLARK. The Appointment is for one year, but may become permanent. Salary £200. Further particulars may be obtained from the Secretary.—Applications, with testimonials, should be sent not later than NOVEMBER 29th.

Princes Street, Truro,
November 15, 1904.

A. BLENKINSOP, Secretary.

Glew's Scintilloscope.

Brilliant Scintillations from PITCHBLÉNDE, Ra, Po, U, Th, or any source of Alpha-Rays.

A Welsbach mantle excites the extremely sensitive transparent screen of the Scintilloscope.

Scintilloscope complete, with 2 in. x 3 in. screen, charged with platinum and pitchblende respectively, in pocket case 7/6 post free.

Pieces of Pitchblende, ground flat, with sensitive screen attached, showing scintillations with any strong pocket magnifier, from 7/6 each, post free.

Radium, &c., for Lectures on fire

THE CHEMICAL NEWS.

VOL. XC., No. 2348.

EMANIUM.

By F. GIESEL.

I HAVE already shown that a Sidot's blende screen is specially suitable for the detection of α -rays (*Berichte*, 1902, xxxv., 3610). By means of such a screen I have discovered a peculiar emanation which is emitted by a substance allied to lanthanum. This emanation characterises my substance; it was further described and its behaviour in the electric field, when the emanation passes over into a radiation, was also established.

From the beginning of my investigations I have repeatedly alluded to the possibility of my substance being identical with Debiere's thorium-actinium, which has as yet not been thoroughly investigated (*Berichte*, 1902, xxxv., 3611; 1903, xxxvi., 344; 1904, xxxvii., 1698; and *CHEMICAL NEWS*, 1904, lxxxix., 267). But as nothing was known of such an emanation of actinium, nor did any notices of it appear during the two years over which the publication of my articles extended, I have finally given the name "Emanium" to my substance, because I was led to assume that its specific properties, which I described, and which could easily be demonstrated, did not belong to actinium. Unfortunately I had no actinium at my disposal for a direct comparison. But in order that there should be no doubt on this point, when I was in Paris recently I asked M. Debiere to compare the two preparations, using a Sidot's blende screen which I had taken with me. It was then seen that the two preparations behaved exactly similarly. Meanwhile Debiere had already spoken of emanium and actinium as identical, without basing his opinion in the least upon the direct comparison suggested by me. Although I share Debiere's opinion in general, and had prepared a manuscript embodying a similar explanation, there are still two facts to which I must allude which might point to a difference between the two substances.

Professors Elster and Geitel have recently kindly determined the constants of decay of the induced activity caused by emanium. As the mean of five experiments which agreed very well together, the following decay curve has been obtained; it follows a simple exponential law:—

Time (minutes)	15	30	45	60	75	90	105	120
Volts	106.0	78.0	58.1	42.9	31.2	22.9	17.2	13.0

Thus the activity of the emanium induction falls to half its value in every 34.4 minutes. As Debiere gives forty minutes for actinium induction, a considerable difference exists. This cannot be directly explained by the somewhat different conditions under which Elster and Geitel worked, especially as they have obtained numbers agreeing perfectly with Curie's in the case of radium and thorium induction.

Secondly, the three lines which indicate the phosphorescence light of my preparations in the spectroscope have not been found in the actinium preparations.

Prof. Hartmann has succeeded in determining photographically the strongest of the three lines accurate to ± 0.1 Angström units, thus obtaining $\lambda 4885.4$. The other two lines, measured less accurately by optical methods, are $\lambda 5300$ and $\lambda 5909$ (*Phys. Zeit.*, 1904, [5], xviii., 570). As these lines could not be identified, they appear to belong to emanium, and it is yet to be discovered whether they occur in actinium also.

Thus, it is yet to be seen whether actinium and emanium are similar in every respect; till this is proved I think it advisable to retain the name emanium.

I have not ascribed any great importance to the chemical

differences between the two substances, which, in Debiere's preparation, are caused by adulteration with thorium, which is itself active, and in my preparation are caused by inactive lanthanum. But I must emphasise the fact that Debiere, for his newer preparations, used, not the thorium from pitchblende, but the cerium earths, as I did, in which he acknowledges the activity is concentrated. When in Paris I saw only these newer preparations of Debiere's, and not his thorium preparations.

I have now arranged some experiments to show how the increase or activity of emanium is to be explained. Since, in the case of emanium, the emanation (or β -radiation) is not driven off—as with radium—by heating or dissolving it, it is possible that a new solid non-volatile substance is formed. The separation of this solid substance from the emanium and rare earths must be effected by means of ammonia, since the freshly precipitated hydroxide of the rare earths loses the β -radiation.

Five to ten grms. of active preparation, which had been kept about a year, in the form of oxide obtained by igniting the oxalate, were dissolved in hydrochloric acid, the rare earths—and with them the emanium—were precipitated with ammonia and the filtrate evaporated.

After the ammonia had been driven off, a very small residue remained, which melted, and consisted principally of strontium chloride, which emitted strong β -radiation and emanation. If the strontium chloride was dissolved in water and the solution filtered until clear, the β -radiation did not disappear; it was only diminished in proportion to the dilution with water. The solution is luminescent. This is the first case to my knowledge in which a solution emits β -radiation strongly and continuously.† If the strontium is precipitated from the solution as carbonate all the activity collects in the precipitate, while the evaporated filtrate is inactive. Yet the strontium salt is not the only active substance. On applying electrolysis an almost invisible yellowish deposit is obtained on the platinum cathode; this emitted intense α - and β -radiation, but no emanation. The platinum anode also, on which nothing is externally visible, was so active that it had a decided effect on the luminescence screen, which, however, was much less than that produced by the cathode. It was noteworthy that the activity of both electrodes had vanished altogether by the next day. As the cathode precipitate pointed to the presence of a heavy metal the same solution of strontium chloride was treated with sulphuretted hydrogen. Only so slight a turbidity resulted that no trace of a precipitate was to be seen on a miniature filter. Nevertheless, its activity was very great. In contrast to the cathode precipitate the activity of the filter was hardly changed after it had been kept for weeks. The remaining strontium chloride solution also possesses considerable activity.

It is noteworthy that the strontium chloride behaves differently from the barium salt artificially rendered strongly active by emanium.‡ The latter loses its β -radiation in solution.

Thus we see that accidental or intentional adulterations of the emanium assume different kinds of active properties. These substances have been partly described already in my earlier article.

In order to make the experiments indisputable if possible, 0.1 gm. of the two purest preparations were subjected to the above treatment with ammonia. The one preparation gave an almost inactive separation, while the second gave strong β -radiation and emanation. In both cases the

† The absence of emanium in the filtrate can be shown physically by the gradual decay of the activity of the residue, which thus differs from emanium.

‡ Water saturated with radium emanation gives some β -radiation. But on heating the solution the emanation is driven off.

§ *Berichte*, 1904, xxxvii., 1698. This quotation may be supplemented by the following note.—The platinum double cyanide of the barium rendered artificially active by emanium reaches its maximum of dark colouration (dichroism) in a few days, while barium containing radium requires weeks or months, which behaviour corresponds exactly to the relative activities as there stated.

residue was so very small that a chemical examination was out of the question. The quantities of substance available were much too small; hence the experiments must be repeated with the 5 or 10 grms. first used, after the maximum radiation has again been reached.

A note may be added on the behaviour of the radium emanation (*Berichte*, 1902, xxxv., 3608).

From about 0.25 grm. of barium bromide containing radium bromide the gas occluded by the crystals and the emanation were driven off by heating in an atmosphere of carbon dioxide, collected over water and washed with carbonic acid. After absorption of the carbonic acid by caustic potash a naturally strongly active gas remained. The volume of the gas increased to at least double its original volume in two weeks. Then no further increase occurred, although it still possessed considerable activity. As I have convinced myself that this increase of volume cannot be caused by diffusion through the column of water I explain this phenomenon to myself provisionally as a decomposition of water caused by the emanation.—*Berichte*, 1904, xxxvii., 3963.

AN ATTEMPT TO EXPLAIN THE IRREGULARITIES OF THE ATOMIC WEIGHTS OF BERYLLIUM, ARGON, AND TELLURIUM.

By E. W. WETHERELL, A.R.C.S.

In the following paper I propose to point out certain relationships between the values assigned to the atomic weights of the elements, and to deduce therefrom a possible explanation of some of the marked irregularities and anomalies.

TABLE I.

Helium 4		Carbon . 12	Oxygen . 16
Neon . . 20	Magnesium 24	Silicon . 28	Sulphur . 32
	Calcium 40	Titanium 48	Chromium 52
—		Germanium 72	
—	Strontium 88		Molybdenum 96
—	Cadmium 112		
Xenon . 128		Cerium . 140	—
—	—	—	—
—	—	—	Tungsten 184
—	Mercury 200		—
—	—	Thorium 232	
—	—	—	—

If we take the number 4 and its multiples up to 4⁴, and arrange those elements of groups 0, 2, 4, and 6, which have multiples of 4 for their atomic weights, in their proper positions, according to the table of Periodic Law, we have Table I.

If in this table we insert the missing multiples of 4 we find that two multiples of 4 occasionally occur in the same space, and, moreover (with the single exception of Be), that the experimental value of these elements always lies within the limits of the two multiples which happen to occur together, e.g., Zn 65.4 lies within the limits of 64 and 68, and Sn 119 lies within the limits of 116 and 120. Ba, again, lies within the limits of 136 and 140 (the two multiples of 4 which happen to be present in the space occupied by barium). This gives us Table II.

If from Table II, we take the first three lines (Table III.) we find that all the elements of the He, Be, C, and O groups are multiples of 4, with the solitary exception of Be. Then since eleven elements agree with the rule of progressive increments of 4 and only one is exceptional, it is important to try to find some reason for the irregularity.

Be is an element which has always given trouble; its sp. heat is abnormal, it is not by any means typical of the group in which it occurs; moreover, it was doubtful for a long time whether its normal oxide was BeO or Be₂O₃, and it has many properties which are more like those of Al than those of Mg. Since the properties of an element are functions of its atomic weight, it is clear that the various unusual properties of Be are dependent on its abnormal atomic weight; in other words, we might expect by inverse reasoning that the atomic weight of Be would be abnormal since its properties are so irregular.

To attempt to elucidate the matter I propose to take an astronomical simile. If observers on another possibly habitable planet had so studied the motions of members of the solar system that they were aware that the attraction of the sun was modified by the attraction of the planets by one another, and yet possessed no telescope by which our moon could be distinguished, they would give too great a mass to the earth itself, as they would be reasoning on the mass of the earth together with that of the moon.

May it not be possible? I proffer the suggestion with all humility, that the atoms of an element may in some cases have a satellite—a minute body inseparable from the atom by any means at our disposal, yet one which may materially affect the properties of an element. Such satellite would in no way upset the law of Avogadro that equal volumes of a gas under equal pressure and temperature contain equal numbers of molecules, as the satellite is an integral part of the molecule; it might even account for the very slight deviation from the law which has been observed.

If this theory be tenable, and if we ever find means of separating the "satellite" from the "planet," we might find that the separated "planet" Be without its moon had an atomic weight of 8, and that its properties were analogous to those of Mg or Ca, whereas at present we are dealing with Be together with its moon, and the increase due to the moon has shifted Be towards aluminium.

To refer again to Table III., there is arithmetical progression from 4 to 52 if argon be taken as 36; we know, however, that argon is not only not 36 but it is so much greater than that value that it is actually higher than K. If, however, the rule holds good that every element in groups 0, 2, 4, and 6 must have a value which is a multiple of 4, or that it lies within the limits of the two multiples of 4 which happen to fall in the particular space allotted to the element; then argon (the planet) should have an atomic weight of 36, and it must then have a moon of the value of 4, which would increase the argon system to 40, thus taking it above the moonless K and up to the normal weight of the next element, calcium.

The inversion of Te and I would be accounted for in the same manner, and the "planet" Te should have an atomic weight of 124 and a satellite of 4, which would bring the

TABLE II.

telluric "system" above that of iodine and up to that of the moonless xenon.

An analogous case to a somewhat lesser extent occurs in the case of Se; this element appears to be too high, and by the multiple of 4 rule its atomic weight should be 76.

If we compare the three sets of values above mentioned we have the results given in Table IV.

When the satellite is very large in comparison with the mass of the planet, as in the case of Be, the properties of the planet are altered (the satellite of Be has a mass equal to one-ninth of the mass of the beryllian system). In the same way argon may also be thrown out, since the satellite of argon is one-tenth of the mass of the argonian system, but in this case we have no proof as argon has no chemical properties. In the other case, the moon of Te is fairly small in comparison, and, consequently, Te is not thrown far out of being a typical member of its group.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY
SAMPLES OF THE WATER SUPPLIED TO LONDON
FOR THE MONTH ENDING OCTOBER 31ST, 1904.

By SIR WILLIAM CROOKES, F.R.S.,

and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, November 10th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board, the results of our analyses of the 211 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from Oct. 1st to Oct. 31st inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 211 samples examined by us during the month, all were clear, bright, and well filtered.

The rainfall at Oxford continues low, the actual amount of rain recorded during the month is only 0.82 inch, the average for October is 2.76 inches; thus we have a deficit of 1.94 inches, which, if subtracted from the previous excess of 0.33 inch, leaves a deficit for the year of 1.61 inches, or 77 per cent on the thirty-five years' average.

Our bacteriological examinations of 382 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 386 others from special wells, standpipes, &c., making 768 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 26 samples) ..	217
New River, filtered (mean of 73 samples) ..	8
Thames, unfiltered (mean of 26 samples) ..	2449
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 203 samples) ..	11
Ditto ditto highest	173
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	271
River Lea, from the East London District clear- water wells (mean of 26 samples) ..	14

Of the 304 daily samples taken from the general filter wells of the Metropolitan Water Board, nineteen samples, or 6.2 per cent, were sterile. Only four samples, or 1.3 per cent, contained more than 100 microbes, and of these only one sample contained more than 150 microbes per c.c. The four excess samples contained an average of 130 microbes per c.c. In September eight excess samples contained an average of 159 microbes per c.c.

The various analyses conducted during the past month show that the general character of the Metropolitan supply was, both from the chemical and bacteriological point of view, remarkably good for the season of the year.

We are, Sir,

Your obedient Servants,

WILLIAM CROOKES.
JAMES DEWAR.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

THE following completes the abstracts of papers received during the vacation and published or passed for publication in the *Transactions*:—

164. "The Effect of Colloidal Platinum on Mixtures of Caro's Persulphuric Acid with Hydrogen Peroxide." By THOMAS SLATER PRICE and JOHN ALBERT NEWTON FRIEND.

Although solutions of hydrogen peroxide and Caro's acid have no appreciable action on each other, the addition of colloidal platinum causes interaction, oxygen being evolved, according to the equation—

or—

The rate of evolution of oxygen gives a measure of the velocity of the reaction; titration methods cannot be used, since there are no accurate methods of estimating hydrogen peroxide and Caro's acid in the presence of each other. It was found that, as long as the platinum was not precipitated out of the solution, the velocity constants, whether of the second or the third order (corresponding with the above equations), continually increased. This increase is considered to be due to two causes:—(1) The gradual increase in the reactivity of the platinum during the reaction; (2) the independent and concurrent decomposition of the hydrogen peroxide and Caro's acid respectively. In some cases, the velocity curve was a straight line.

The effect of varying the concentration of the platinum was also studied, but no definite connection between concentration and velocity could be traced, except that a diminution in velocity was associated with a decrease in concentration of the platinum. In alkaline solutions, the results obtained were indefinite, since interaction takes place in the absence of platinum, and the velocity seems to depend on the rate of stirring.

165. "The Acylation of Amides." By ARTHUR WALSH TITHERLEY.

The conversion of a primary into a secondary amide and a secondary into a tertiary amide cannot, in general, be effected by treatment with acyl chlorides and anhydrides, but by first replacing the hydrogen of the —CO·NH_2 or —CO·NH·CO— group by sodium; the resulting sodium acylamide reacts usually with considerable energy with acyl chlorides, or, preferably, anhydrides, yielding acylated derivatives. Sodium benzamide and benzoic anhydride, for example, yield sodium dibenzamide and benzoate. At the same time, a tertiary amide (tribenzamide) is formed owing to the interaction of a portion of the sodium dibenzamide and benzoic anhydride.

Although the action is normal in the aromatic and aliphatic series respectively, abnormal results are obtained on attempting to apply the method to the synthesis of mixed aliphatic aromatic secondary amides. Thus, neither sodium acetamide and benzoic anhydride nor sodium benzamide and acetic anhydride yield the expected acetylbenzamide in appreciable quantity, the main product of either of these condensations being sodium dibenzamide.

Cyclic anhydrides appear to behave normally. Thus, succinic anhydride and sodium benzamide give rise to benzoylsuccinimide (needles, m. p. 180°) and s-dibenzoylsuccinimide (m. p. 211°).

A further application of sodium acylamides for the purpose of acylation is based on their condensation with esters (*Trans.*, 1902, lxxxi., 1520), but the condensation is abnormal with esters and sodium acylamides which contain the groups $\text{—CH}_2\text{·CO}_2\text{Et}$ and $\text{—CH}_2\text{·CO·NHNa}$ respectively. Methyl oxalate yields the disodium derivative of dibenzoyloxamide, but benzoyloxalimide, which was also anticipated, is not produced.

s-Dibenzoyloxamide (m. p. 227°) is readily soluble in sodium hydroxide, but the solution readily undergoes hydrolysis, forming benzamide and sodium oxalate. Ethyl succinate and sodium benzamide readily react, but do not yield either ethyl benzoyl succinamate, dibenzoylsuccinamide, or benzoylsuccinimide; the chief products are sodium succinimide and ethyl benzoate.

A very convenient process for acylating amides direct consists in treating directly with the acyl chloride the amide dissolved in pyridine (compare Freundler, *Comptes Rendus*, 1902, cxxxvi., 1553; 1903, cxxxvii., 712–714). The method is limited in the same sense as the sodium acylamide anhydride method, since in this case also aromatic acyl radicals tend to displace aliphatic groups; hence it is impossible to prepare acetylbenzamide from benzoyl chloride and a pyridine solution of acetamide. That the method may be applied to the acylation of secondary as well as primary amides is shown by the fact that dibenzamide when subjected to this process yields 50 per cent of tribenzamide.

Benzoylsuccinimide (m. p. $129\text{—}130^\circ$) is readily obtained by the action of benzoyl chloride on a pyridine solution of succinimide.

166. "The Composition of Beryl." By JAMES HOLMS POLLOCK.

The irregular results obtained on the analysis of compounds of glucina, prepared from various samples of the oxide, suggested that there was something in the composition of the beryl that had so far been overlooked.

The glucina employed was extracted from Limoges beryl during a previous research, and was known to give too high an equivalent, although analysis failed to indicate the presence of aluminium or any other base. This glucina was fractionated by crystallisation of the sulphate, by solution in ammonium carbonate, and by precipitation from hydrofluoric acid solution by potassium hydrogen fluoride. The glucina was recovered from the various fractions, converted into anhydrous chloride, and the various specimens of this salt analysed. In certain fractions, a progressive rise in the equivalent of the base was observed, giving figures ranging from 4.77 to 8.17.

Samples of glucinum chloride were then fractionated by distillation, the most volatile and least volatile portions being analysed separately. Three samples of the most volatile portions yielded equivalents of 9.08, 10.81, and 11.29.

Other fractions obtained by collecting the chloride that was first formed, apart from that which distilled over later, gave, on analysis, equivalents of 12.30, 14.80, and 15.74.

Only a small quantity of the chloride with the highest equivalent was obtained; the most careful analysis failed to detect it in the presence of aluminium, iron, or any other element, the sample having the chemical properties of glucinum only.

A spectroscopic examination of the various specimens with high equivalents showed that certain lines, only faintly visible in ordinary samples of glucina, became steadily stronger as the equivalent increased, and the known lines of glucinum became somewhat fainter.

These results indicate that beryl contains a new element having in the main the chemical properties of glucinum, but a much higher equivalent; its chloride is more volatile and more readily formed than that of glucinum, and the oxide is not so readily precipitated from a hydrofluoric acid solution by potassium hydrogen fluoride.

Ordinary Meeting, Thursday, November 3rd, 1904.

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

Messrs. C. R. Beck, J. H. Johnston, R. Lessing, J. Marsh, and H. S. Shelton were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. Walter Henry Bentley, B.A., 18, Oaten Hill, Canterbury; John Wyclif Black, 20, Mardale Crescent, Edinburgh; Thomas Story Busher, B.A., Queen's College, Oxford; Lawrence Caldecott, 47, Woburn Place, Russell Square, W.C.; Robert John Caldwell, B.Sc., A.C.G.I., 49, Merritt Road, Crofton Park, S.E.; Peter Skinner Clark, M.B., Ch.M., Cape Town, Cape Colony, South Africa; Frederick Clarkson-Harold, 10, Fee's Terrace, Longford, Ireland; Robert Cornthwaite, Agricultural Laboratory, Halifax; William Crabb, B.Sc., The Grammar School, Penistone, Yorks; James Edward Cunningham, A.R.C.S., 21, Blenheim Gardens, Willesden Green, N.W.; Harold Deane, B.Sc., 34, Drakefield Road, Upper Tooting, S.W.; Francis Dickinson, 26, O'Connell Avenue, Berkeley Road, Dublin; Edward Evans, 33, Ranelagh Road, Westminster, S.W.; Thomas Wallace Fagan, B.A., Harper Adams Agricultural College, Newport, Salop; John Kerr Forrest, Hawsleigh, Balacava Road, St. Kilda, N.S.W.; Thomas Reginald Hodgson, The Sycamore, Poulton-le-Fylde, Lancs.; George William Thomas Horrod, 294, Brixton Hill, S.W.; John Kenneth Harold Inglis, M.A., B.Sc., University College, W.C.; Thomas Campbell James, B.A., B.Sc., 4, Belmont Terrace, Llanelli; Walter Richmond James, 49, Wednesfield Road, Wolverhampton; John Richard Johnson, Apothecaries' Hall, E.C.; Horace Francis Jones, 3, Kerry Crescent, Calne, Wilts; William App Jones, A.B., A.M., Ph.D., 12E, 18th Street, New York; Alfred Francis Joseph, A.R.C.S., 95, Marylands Road, Maida Vale, W.; James Stanley Lauder, c/o B. Harvey, Qu'Appelle, N.W.T., Assa., Canada; Arthur Garfield Levy, B.Sc., A.I.C., c/o B. Blount, Esq., 76, York Street, S.W.; James Patrick Longstaff, B.Sc., 19, Fettes Row, Edinburgh; Arthur Thomas McDougall, B.A., 3, Albion Road, College Park, S.E.; Harold Joseph Clarke Mathews, Massey's Brewery, Ltd., Burnley, Lancs.; Ernest Westby Millar, A.R.C.S., Windsor, Monkstown, Co. Dublin; Marie Jean Louis Ernest Rouillard, B.Sc., Malvern, Natal; Percy Edwin Spielmann, A.R.C.S., 21, Cadogan Gardens, S.W.; Harry Stanley, B.Sc., The Park, Southend Village, Catford,

S.E.; Thomas Sutcliffe, 19, Rhodes Street, Halifax, Yorks.; Paul John Thibault, Howell, N.S.W.; Douglas Frank Twiss, M.Sc., 89, Wood Lane, Harborne, Birmingham; Herbert Wood Watson, B.Sc., 111, Brudenell Road, Hyde Park, Leeds; William Henry Willcox, M.D., B.Sc., F.I.C., St. Mary's Hospital, W.; Frank John Wyeth, M.A., 14, Preston Drive, Brighton.

The PRESIDENT, in announcing the lamented death of Professor Lobry de Bruyn, which occurred in July, after a short illness, reminded the Society that the deceased was one of the Honorary Foreign Members elected recently. A letter of sympathy and condolence had been immediately sent in the name of the Society to the widow, and it was hoped that an obituary notice would shortly appear in the *Journal*.

Of the following papers, those marked * were read:—

*167. "Studies on the Dynamic Isomerism of α - and β -Crotonic Acids." (Part I.) By ROBERT SELBY MORRELL and EDWARD KENNETH HANSON.

To show the change in the melting-point with variation in the composition of a mixture of α - and β -crotonic acids at temperatures below the melting-point of the less fusible component (α -crotonic acid), weighed quantities of the α -acid were added to a known weight of the β -acid, and the freezing-point of the mixture observed. It was found that the freezing-point of the β -crotonic acid fell from 14.96° to a minimum of -1.1° , and then rose to 43.9° on gradual addition of the α -acid until the mixture contained 30.8 per cent of the β -acid. To complete the melting-point curve, the lowering of the freezing-point of α -crotonic acid by the β -isomerism was observed, and it was found that the curve was a continuous one from 15° through -3° (eutectic-point) to 71.9° . There is no compound of α - and β -crotonic acids between these temperatures.

The investigation on the composition of the two acids at temperatures between 100° and 168° showed that β -crotonic acid changed on heating into the α -modification, and the composition of the mixture was found by cooling the fused mass rapidly and determining its freezing-point. From the observed values of the freezing-points for known mixtures of the two acids, the composition of the mixture was fixed without having recourse to estimation by chemical methods. At 168° , the curve showing the transformation of the β -acid into the α -acid met the similar curve for the α -acid changing into the β -acid; the composition at this point was 76 and 24 per cent of the α - and β -acids respectively. The boiling-point under the ordinary pressure of a mixture of α - and β -crotonic acids is 168 – 174° (compare Michael, *Journ. Prakt. Chem.*, 1892, [2], xlv., 146).

These preliminary experiments furnish no evidence as to the existence of a compound of α - and β -crotonic acids between 100° and 168° .

*168. "The Constitution of Nitrogen Iodide." By OSWALD SILBERRAD.

The empirical formula of nitrogen iodide has been established by Chattaway (*Am. Chem. Journ.*, 1900, xxiii., 363, 369; and 1901, xxiv., 138, 159, 318, 330, 342) as N_2I_3 , but the analytical results obtained by earlier workers showed great variations, chiefly due to unsuitable methods of preparation, insufficient precautions against the decomposing action of light, and faulty methods of analysis. In view of the methods of preparation and properties of the compound, the formula $N_2H_3I_3$ admits of two possible constitutions, $NH_3 \cdot NI_3$ and $NH_2I \cdot NH_2I$. Chattaway's work does not differentiate between these two formulae, and the earlier investigations offer no further proof as to the constitution. On the one hand, the liberation of ammonia by the action of acids supports the former configuration, whilst the formation of di-iodomethylamine by the action of methyl iodide appears to render the latter formula probable.

Non-direct derivatives of nitrogen iodide have so far been prepared in a pure state, the metallic compounds in-

vestigated have been incorrectly formulated owing to impurities in the products, and the only organic derivatives of nitrogen iodide hitherto obtained are those prepared by Stahlschmidt (*Poggendorff's Ann.*, 1863, cxix., 421) by the action of methyl iodide. These substances are so indirectly related to nitrogen iodide that they afford no definite proof as to its constitution.

In order to obtain substitution products closely related to nitrogen iodide, the action of zinc ethyl has been studied, and in this way it has been found possible to obtain direct proofs as to the constitution of the iodide.

Zinc ethyl reacts slowly with nitrogen iodide, producing volatile paraffins together with a white amorphous compound, insoluble in ether, from which ammonia and triethylamine are obtained on treatment with dilute acid and subsequent distillation with aqueous caustic potash. From this it is evident that the constitution of nitrogen iodide is represented by the formula $NH_3 \cdot NI_3$, and that the action of zinc ethyl proceeds according to the equation:—

This formula for the iodide is also supported by many of the observations of earlier investigators.

DISCUSSION.

Dr. CHATTAWAY recalled the fact that in conjunction with Dr. Orton (*Am. Chem. Journ.*, 1901, xxiv., 342) he had shown that the formula $H_3N \cdot NI_3$ alone could explain the actions which take place when nitrogen iodide is slowly decomposed by a stream of water. In such a progressive decomposition, this molecule is broken up and the ammonia washed away, while NI_3 mixed with iodine remains in the solid residue. If the ratio $N:I$ could have been obtained, the formula would have been established beyond question, but, owing to the accumulation of iodine, a possibility of experimental error was introduced, and the ratio $1:18N:I$ was the nearest approach to this on which they felt able to rely confidently; this ratio, however, excludes all formulæ except the one they put forward. Although he regarded this formula as undoubtedly correct, nevertheless, Dr. Silberrad's evidence was not quite conclusive. He drew attention to the small yield of triethylamine, and suggested that under the experimental conditions much of the base would be found in combination with ethyl iodide as tetraethylammonium iodide. It seemed unlikely that nitrogen iodide could be properly dried in quantity by washing with alcohol and afterwards with ether, especially as the compound so very readily interacted with alcohol with the production of ethyl iodide, aldehyde, and ammonia. The triethylamine obtained under these conditions might have been formed by the interaction of ethyl iodide and the liberated ammonia.

He hoped to be able shortly to publish the results obtained by the study of the interaction of nitrogen iodide and the magnesium alkyl compounds, particularly the benzyl derivatives.

Mr. SMART, in replying on behalf of Dr. Silberrad, who was absent, stated that, although ammonia was produced in quantitative yield by the interaction of nitrogen iodide and zinc ethyl, yet the proportion of triethylamine obtained in these experiments was so small that it could not be detected until the experimental conditions had been carefully worked out, and even then large quantities of the iodide had to be treated in order that the base might be isolated and identified. The personal risk involved in treating a kilogram of nitrogen iodide under ether with zinc ethyl was very small in comparison with the danger incurred in dropping the dry iodide into an ethereal solution of zinc ethyl. He believed that a pure metallic derivative of the nitrogen iodide had actually been obtained, and that a paper on this subject would shortly be communicated to the Society.

*169. "The Available Plant Food in Soils." By HERBERT INGLE.

The results of the author's investigation of the available plant food in soils lead to the following conclusions:—

1. That extraction with a 1 per cent solution of citric acid for seven days renders a soil much less fertile, especially at first, but that chemical changes in such soil, during the growth of the plants, gradually render it again capable of supplying plant food.

2. That beans are able to extract a larger portion of the potash and phosphoric acid present in the soil than barley. This was especially so in the case where extracted soil was used.

3. That Dyer's method (*Trans.*, 1894, lxx., 115) of determining "available" plant food in soils is of considerable value in estimating their relative fertility, but that another factor must be considered, namely, the rate at which the "available" plant food is renewed, especially if the soils exist under different climatic conditions.

Whilst this is probably the same or nearly so for soils under similar climatic conditions, it may be, and probably is, very different in tropical or sub-tropical soils to what it is in those of temperate climates.

DISCUSSION.

Dr. DYER said he had seen photographs of Mr. Ingle's pot culture experiments, and these certainly seemed to confirm the view that the phosphoric acid and potash soluble in 1 per cent citric acid solution corresponded with the quantity of those constituents immediately available as plant food. But the most interesting part of Mr. Ingle's work on the subject was that showing the recuperative power of soils even after they had been artificially denuded of immediately available mineral food.

170. "The Basic Properties of Oxygen: Compounds of the Ethers with Nitric Acid." By JULIUS BEREND COHEN and JOHN GATECLIFF.

In view of recently published results on the additive compounds of the ethers, the following observations, which were made early in the year, may be of interest:—In extracting with ordinary ether the products of the nitric acid oxidation of substituted toluenes, it was frequently observed that, after dehydrating and removing the ether on the water-bath, a small quantity of yellow liquid remained which had a characteristic odour, quite unlike that of ether. If this liquid were more strongly heated, or even left for a time, it decomposed with a succession of little explosions and the evolution of nitrous fumes. The liquid is produced by the action of nitric acid on ether and behaves qualitatively like a mixture of these two substances. When added to strong sulphuric acid, nitric oxide is evolved; this result being also obtained by adding strong nitric acid to a mixture of strong sulphuric acid and ether. The liquid behaves like nitric acid to phenol, benzene, and aniline. In order to ascertain whether it had a definite composition the following experiments were made:—Definite volumes of the purified ether and dilute nitric acid (1 HNO₃ : 2 H₂O) were shaken up in a separating funnel, the lower layer was removed, and the ethereal layer dehydrated for twenty-four hours over anhydrous sodium sulphate. The excess of ether was then removed by distillation until the thermometer registered 50°, when the process was stopped, for if the temperature rises above this point decomposition occurs and brown fumes are evolved. Air was now blown into the pale yellow residue contained in a beaker until the odour of ether had almost disappeared. As in this state the liquid decomposes rapidly at the ordinary temperature and slowly even at 0°, quantities of 1 to 2 grms. were rapidly weighed and made up with water to 100 c.c. A measured volume was then titrated with standard caustic soda, using methyl-orange as indicator. The following results were obtained with purified methylated ether, ethyl ether, and propyl ether:—

Ether employed.	Percentage of nitric acid in the product.	Volumes of ether and dilute nitric acid taken.	
		HNO ₃ . C.c.	Ether. C.c.
Methylated ether ..	{ 45·2	50	: 50
	{ 44·4 (a)	50	: 50
	{ 44·4	25	: 50
Ethyl ether	{ 47·3	50	: 50
	{ 47·5	50	: 50
Propyl ether	{ 33·8	50	: 50
	{ 35·9	50	: 50

(a) The ether in this case was not distilled, but evaporated at the ordinary temperature under 20 m.m. pressure.

The calculated amounts of nitric acid corresponding with the formulæ (C₂H₅)₂O, HNO₃ and (C₃H₇)₂O, HNO₃ are 46 and 38·2 per cent respectively. The agreement in the case of ethyl ether is quite satisfactory. The compound with propyl ether is evidently less stable at the ordinary temperature, the affinity for nitric acid appearing to diminish with increasing molecular weight. Amyl ether and dilute nitric acid have no interaction at the ordinary temperature, and this is also the case with dimethylquinol, the only aromatic ether investigated.

171. "The Condensation of Formaldehyde with Acetone." (A Preliminary Note). By EMIL ALPHONSE WERNER.

When acetone is mixed with a 40 per cent solution of formaldehyde, no interaction takes place until a small amount of alkali is added; if the liquids are mixed in the undiluted form, the addition of a small amount of caustic potash causes, after a few moments, a very violent reaction, the liquid boils, and an orange-red resinous condensation product separates.

When the substances are mixed in 10 per cent aqueous solution, the reaction proceeds much more slowly, the liquid gradually assumes a dark yellow colour, showing a green fluorescence; after one hour, the condensation product commences to separate as a bright orange-yellow powder, and at the end of twenty-four hours the reaction is complete. During the change, the alkalinity of the liquid diminishes considerably. The condensation product, when thoroughly washed and dried, forms an orange-yellow amorphous satiny powder with a peculiar odour. It has the empirical formula C₄H₆O; analysis gave C = 68·97 and 69·58, H = 7·46 and 7·54 per cent, whilst the calculated percentages are C 69·56, H = 7·24. The compound is freely soluble in alcohol, acetone, or glacial acetic acid, and is precipitated unchanged by water; it dissolves sparingly in benzene, chloroform, or ether. The same substance is produced whether the acetone or the formaldehyde be used in excess.

It might have been expected that a compound having the compound C₄H₆O, that is, a polymeric of CH₂:CH:CO:CH₃ (C = 68·56, H = 8·56), would have been formed; this, however, does not appear to be the case. With bromine in glacial acetic acid solution, it behaves as a saturated compound, hydrogen bromide is evolved, and a mono-brominated derivative formed, which separates on diluting with water as a dark brown powder.

The addition of hydrochloric acid to the alkaline filtrate from the original experiment produces a yellow precipitate having the same composition as the orange-yellow condensation product.

172. "The Union of Hydrogen and Chlorine. Rate of Decay of the Activity of Gaseous Chlorine." By JOSEPH WILLIAM MELLOR.

The rate at which active chlorine returns to the ordinary condition follows the exponential law $x = x_0 e^{-at}$; where x denotes activity at time t , and a and x_0 are constants (a being 2·2 approximately). This is true when the activity is induced either by the electric discharge or by exposure to light.

(To be continued).

PHYSICAL SOCIETY.

Ordinary Meeting, November 11th, 1904.

Dr. R. T. GLAZEBROOK, F.R.S., President, in the Chair.

A PAPER on the "Investigation of the Variations of Magnetic Hysteresis with Frequency," by Prof. T. R. LYLE, was read by Prof. TROUTON.

The experiments were made on two rings of laminated annealed iron, in one of which the radial breadth of the iron was considerable relative to its mean radius. These rings were magnetised by alternating currents of different strengths and periods; both the magnetising-current wave and the magnetic-flux wave were quantitatively determined by a wave-tracer (described by the author in the *Phil. Mag.*, November, 1903), and the wave-forms so obtained subjected to harmonic analysis. The experiments were divided into series, in which the period and wave-form of the magnetising current were kept as nearly constant as possible throughout any one series, while its strength was varied. The analytic expressions for the associated current and flux waves for a few series are given in tabular form. From the analytic expressions for each pair of associated waves it was found that when the magnetising current was approximately sinusoidal the total iron loss (I) was, within certain limits of the induction, given by a formula, $I = (a + bn) B^{1.57}$; where n is the number of periods per sec., B the "effective induction," and a and b are constants. When from the total iron loss per c.c. per cycle the sum of the static hysteresis and the value that theory assigns to eddy current loss was subtracted, a considerable quantity remained, which increased both when the frequency and the flux-density increased. This quantity, called by Fleming the kinetic hysteresis, has been obtained for each experiment. An interesting case of transformation and what is called reflexion of energy is drawn attention to and discussed. If the E.M.F. impressed on the magnetising circuit on the iron ring be sinusoidal, the flux-wave produced contains third, fifth, &c., harmonics. These higher flux harmonics induce currents in the magnetising circuit which are dissipated as heat in it. Thus we have a transformation of electrical energy due to alternating currents of frequency n to energy of currents whose frequencies are $3n$, $5n$, &c., which is reflected back into the magnetising circuit. This the author believes is a hitherto unnoticed source of transformer loss.

Dr. J. A. FLEMING said the paper appeared to contain many points of interest. The result given by the author, that the total iron losses varied as the 1.57 power of the induction density, agreed with practice. There was, however, no hard and fast law for the calculation of the iron losses, but the number 1.6 was useful as a guide. In many cases the loss varied according to an exponent considerably less than 1.6. He pointed out that this exponent was practically the same for all magnetic metals, and said it would be interesting to know if the law would be true in the case of a Ewing model of a magnet. The paper clearly showed that transformer losses should be determined by measuring the watts. The experimental determination of the static hysteresis was not of practical importance; what was wanted was the real loss, which varied with the frequency. We should be able to calculate the loss at any induction and frequency from the known loss at any particular induction and frequency.

Mr. A. CAMPBELL drew attention to the work of an earlier investigator on the same subject. Max Wien, in a paper on "Magnetisation by Alternating Currents" (*Wied. Ann.*, xiii., August, 1898), gives results of an investigation on the change in flux-density and hysteresis loss due to variation in frequency of the magnetising alternating current. His chief method of measurement was based on Maxwell's method of comparing two self-inductances. One of the inductive coils so compared was the winding of the iron ring under test, the source of voltage being alternating (128 to 520 ~ per sec.), and the indicating

instrument a tuned optical telephone or vibration galvanometer. The bridge measurement (starting with direct current) gave the "effective" resistance and self-inductance of the ring winding, and from these (with the dimensions, &c.) were deduced the values of B and the hysteresis loss due to the fundamental component of the alternating flux, allowance for eddy-currents having been made. A number of conclusions are drawn from the results; amongst others, that increase of frequency decreases B for a given value of H , and increases the hysteresis loss for a given value of B . This appears to indicate that with quickly alternating fields B lags behind H . It is interesting to notice that for one of the rings tested the "kinetic hysteresis" found for $n=128$ is of somewhat the same order of magnitude as that given by the rings of Prof. Lyle at lower frequencies.

The SECRETARY read a letter from Dr. D. K. MORRIS giving particulars of similar experiments carried out at the University of Birmingham.

Mr. T. H. BLAKESLEY said that ten or twelve years ago he read a paper before the Society describing experiments which pointed to the existence of kinetic hysteresis. The present paper substantiated what he had said then.

A paper "On the Practical Determination of the Mean Spherical Candle-power of Incandescent and Arc Lamps," by Mr. G. B. DYKE, was read by the Author.

Mr. Dyke points out the need of an improved method of expressing the efficiency of glow-lamps, and adopts the suggestion of Dr. Fleming of expressing the whole flux of light in lumens per watt. The expression of the efficiency in this manner involves the determination of the mean spherical candle-power (M.S.C.P.), and the paper describes a method of doing this. The objects of the paper are (1) to obtain curves showing the variations of candle-power of glow-lamps in a horizontal plane, (2) to obtain reduction factors by which the mean horizontal candle-power (M.H.C.P.) may be calculated from the maximum horizontal candle-power (C.P.), and (3) to obtain reduction factors for deducing the M.S.C.P. from the M.H.C.P. and from the C.P.

A self-contained motor-driven lamp-holder is described which rotates the lamp about a vertical axis at from 230 to 300 revolutions per minute. The M.H.C.P. was determined by spinning the lamps, and by taking C.P.s. in different azimuths by a step-to-step method. The results agreed within the limits of experimental error, thus showing that the filaments were not sensibly distorted during rotation.

An integrating photometer was used to determine the ratio (M.S.C.P.)/(M.H.C.P.). This instrument is of the type suggested by Mr. C. P. Matthews, and consists of several pairs of mirrors placed around the circumference of a semicircle, and so arranged that light emitted from a source placed at the centre of the system is incident upon the photometer screen, also situate at the centre, at the same angle with the vertical as it made on emission from the source. It is shown how the ratio (M.S.C.P.)/(M.H.C.P.) can be determined by observing one distance after obtaining a photometric balance. The effects of any departure from Lambert's cosine law and of varying reflection coefficients of the mirrors were investigated and allowed for. It was also found impossible to reduce the size of the apparatus by interposing ground-glass screens because of the varying absorption of ground-glass for light of different colours. Nine types of glow-lamp were experimented upon, and the high peaks and depressions on the curves of horizontal intensity were ascribed respectively to a mirror action of the bulb, and to portions of the filaments obstructing the light from other portions. Values of the ratios (M.H.C.P.)/(C.P.), (M.S.C.P.)/(C.P.), and (M.S.C.P.)/(M.H.C.P.), have been obtained, and for lamps of the same type of filament it is found that the ratio (M.S.C.P.)/(M.H.C.P.) is remarkably constant. The author therefore suggests the determination of the M.H.C.P. by means of a rotator, and then, with the aid of a reduction factor, determined once and for all for a particular type of

filament by an integrating photometer, the deduction of the M.S.C.P. Preliminary experiments upon arc-lamps seem to show that a similar method may be adopted for the determination of their M.S.C.P.

Dr. J. A. FLEMING congratulated the author, and referred to the peculiar difficulties under which the research had been conducted at University College. Two features of the integrating photometer used were the possibility of compensating departures from the cosine law by the setting of the mirrors and the determination of the M.S.C.P. from one reading. It was now as easy to obtain a value for the M.S.C.P. as to obtain a useless measure of the horizontal intensity in any particular direction. The variation in the reflecting powers of the mirrors due to dust and dirt could also be eliminated.

Mr. PATTERSON gave an account of similar experiments which were being carried out at the National Physical Laboratory. Referring to the fact that the author had taken for his zero position in determining the ordinary C.P. of a lamp, that in which the mean plane of the filament was at right angles to the axis of the photometric bench, he pointed out that this position was unsatisfactory because of the prevalence of streaks and shadows on the screen. The M.H.C.P., and not the C.P. in any particular direction, was the only unit now in use. The results of the author were in close agreement with those obtained at the National Physical Laboratory.

Mr. W. DUDELL pointed out that if the peaks in the curves of horizontal intensity were due to reflection from the bulb, one would expect that their position would vary with the distance between the lamp and screen. He asked the author if he had noticed any such variation. The integrating photometer described in the paper was very cumbersome, and he would like to know in what respects it was superior to Blondel's lumenmeter.

Dr. C. CHREE remarked that it would be interesting mathematically to express the illumination in a series of spherical harmonics.

The CHAIRMAN expressed his interest in the fact that some of the results of the author had been confirmed by Mr. Patterson at the National Physical Laboratory. He had recently been in America, and found that the integrating photometer was in use for measurements upon arc-lamps, but that incandescent lamps were measured with a rotator, no particular regard being paid to the M.S.C.P. With regard to the observations of Dr. Chree, he said that Mr. Patterson could give him sufficient details to carry out the calculations.

The AUTHOR, in reply to Mr. Duddell, said that although he had not varied the distance between the lamp and the screen, he had taken photographs of the "blaze" of the lamp at different distances, and found that it was always the same.

Exhibition of Apparatus by Mr. R. W. PAUL.

The construction of highly sensitive pivoted electrical instruments has been rendered difficult by the fact that delicate pivots will not admit of transporting without injury. A number of galvanometers were shown in which the design was based upon the use of a moving coil, supported on one pivot in a powerful and uniform magnetic field, and controlled by a spring. The adoption of one, in place of the usual two pivots, renders it feasible to raise the coil when the instrument is out of use, and thus secure the pivot from risk of injury. By taking advantage of this, and the incidental reduction of pivot friction, a practical instrument has been made approaching in sensibility to that of a reflecting galvanometer. Some of the instruments exhibited gave a full scale-reading of 100 divisions for 2 millivolts or for 60 micro-amperes. Combined with shunts and resistances other forms gave direct reading insulation measurements to 2500 megohms, pressures to 500 volts, and currents to 25 milli-amperes in the one apparatus. Demonstrations were given of the suitability of the galvanometers for pyrometer use. The galvanometers are so designed that accurate levelling is unnecessary. A simple

non-reflecting, suspended-coil galvanometer for the student's use, with a sensibility of one division per micro-ampere, was also exhibited.

A new design of lantern, adapted for science lectures, and for use with a powerful arrangement of Nernst filaments arranged closely together, was shown in action. It is capable of being instantly changed from horizontal to vertical projection, can be fitted with a reversing prism, and has a wide adjustment for focussing. Another exhibit was an Ayrton Mather reflecting electrostatic voltmeter with a magnetic damping device. The instrument shown had a sensibility of 500 m.m. at 1 m. for 30 volts, but similar instruments are made to give this deflection with pressures as low as 8 volts.

NOTICES OF BOOKS

Elements of Inorganic Chemistry. ("Éléments de Chimie Inorganique"). By Prof. Dr. W. OSTWALD. Translated into French by L. LAZARD. Part I. *Metalloids*. With 106 Figures in the Text. Paris: Gauthier-Villars. 1904. Pp. 542.

THE object of this work is to bring the student at once in contact with modern conceptions instead of first teaching him old and insufficient theories which have to be eventually replaced by others. For this purpose it has been necessary to modify considerably the plan on which most text-books on chemistry are written.

The author has retained the historic order of chemical science, though it might have been an advantage to elaborate, first of all, a certain number of principles, and only to give the descriptions of chemical substances for the purpose of illustrating or clearing up these general laws.

Such a book as this appeals to two classes of readers, the teachers and the pupils; it has thus a double duty to perform, which has naturally increased the difficulties met with by the author. He has, however, always leaned towards the side of the student; that is to say, he has made his descriptions more explicit than would have been necessary had he been addressing the teachers only.

The book is divided into nineteen chapters, commencing with "General Principles." He then deals with oxygen, hydrogen, water, and peroxide of hydrogen; these subjects bring us to Chapter VIII. Chapters IX. to XI. deal with chlorine, bromine, iodine, and fluorine; while Chapter XII., a long one, is devoted to sulphur and its compounds, and Chapter XIII. to selenium and tellurium. We then have five chapters dealing respectively with nitrogen, phosphorus, carbon, silicon, and boron; while Chapter XIX., the last, is on argon, and the analogous elements, helium, neon, krypton, and xenon.

There is a good table of contents, but unfortunately no alphabetical index.

Elementary Manual for the Chemical Laboratory. By LOUIS WARNER RIGGS, Ph.D. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

THIS manual provides students with a guide for one year's laboratory work, assuming that they are attending a suitable lecture course at the same time. The students who use the book are supposed to have no previous knowledge of chemistry, though they are not to be altogether ignorant of physics, and the demonstrator is warned that he will probably be required to teach the students arithmetical analysis, with which subject, apparently, first year college students in America are generally unfamiliar. The experiments are chosen with a special view to the requirements of large classes of from 30 to 40 students, and are divided into three parts. The first deals with general chemistry, the lecture course following the older method which was

universally adopted in teaching chemistry in England ten years ago. Thus the first lecture is devoted to defining and explaining various chemical and physical terms, which are then illustrated in the laboratory by the examination of the properties of sulphur. Then hydrogen, oxygen, and their compounds would be taken up in lecture, and prepared and examined in the laboratory, followed by a discussion of the laws of chemical action and the atomic theory, which are illustrated by a few practical examples of the preparation of a compound from its constituent elements; these experiments, however, miss their mark, since no attempt is made to perform them quantitatively. And so on through all the elements. The extremely difficult problem of what to explain at length, such as the meaning of "weigh accurately about 2 grms.," and the method of folding filter-papers, and what to leave to a few words from the demonstrator, has not been very satisfactorily solved. The second part deals with the study of volumetric analysis, in which a good course is given, followed by a few pages on the gravimetric analysis of a single compound, magnesium sulphate, the student being directed to read general directions for gravimetric work in some other manual of quantitative analysis. In the last section, the general principles of qualitative analysis are described, using ionic notation throughout; no separation tables are given, the author being of the opinion that they are better omitted in a first year's work. Some peculiarities of nomenclature, e.g., the description of magnesium as a basylous element and the spelling will militate against the use of the book in English laboratories, and there will be found no lack of choice among considerably better books on practical chemistry.

Lectures Scientifiques. ("A French Reader for Science Students"). By W. G. HARTOG, B.A. London: Rivingtons. 1904.

This book is intended specially for the use of candidates at the examinations for the science degrees of the University of London, who are now required to show sufficient acquaintance with French and German to enable them to read scientific papers in these languages. The author has found a difficulty in providing his students with suitable and sufficient material, and has accordingly published this collection of extracts on physics, chemistry, physiology, mathematics, and botany, taken from standard text-books, such as Hoefer's "*Histoire de la Physique*." The extracts are excellently chosen, so that an intelligent student who reads through them can hardly fail to become thoroughly at home among the terms and phraseology of these sciences in French. The papers on botany, in which subject it was no doubt more difficult to obtain suitable extracts, will perhaps be found the least interesting, while those on physics are in many respects the best. The book, which contains a glossary of technical words and of such as are not to be found in an ordinary dictionary, can be highly recommended as excellent for its purpose.

A Text-book of Quantitative Chemical Analysis. By J. C. OLSEN, A.M., Ph.D. New York: D. Van Nostrand Company. 1904.

It may be confidently stated that this book will rank among the best procurable on the subject of quantitative analysis. The student who uses it has placed before him a high standard at which to aim, and if he catches some of the spirit of the book he cannot fail to become an accurate and conscientious worker. In the directions for the performance of all experiments the most minute details and precautions are given as an incentive to great carefulness, and these are prefaced by admirable discussions of all the theoretical aspects of the analyses to be performed, so that before proceeding to the practical work the student should be thoroughly acquainted with the reasons for every step

he is to take. After the gravimetric determinations of metals and acids and the analysis of some few alloys and typical minerals, a short but complete course of electrolytic work is given, which alone marks the book out as specially commendable. It is curious to notice that the student is advised to weigh out exactly certain quantities of substance, since he will most probably find that he will weigh more quickly than perform the necessary calculations—a plan which most workers would hardly be inclined to adopt. In the Analysis of Technical Products it does not appear that the best choice of subjects has been made; for instance, no descriptions are given for the methods of determining sugars, which are, generally speaking, processes requiring practice and skill, and are yet quite within the powers of the average student, while the analysis of fats and oils can necessarily only be treated very cursorily. The chapters on Volumetric Analysis and Gas Analysis are excellently written and are most complete, especially in the case of the former. We have read this book from the point of view of the needs of the student, for whom the author has specially written, and by whom it will probably be most appreciated. As a work of reference for the technical chemist the omission of the determination of the less common metals, and of various plans which may be adopted when there is a likelihood of many similar determinations having to be made, will diminish its usefulness; for instance, in a technical laboratory it is well worth while to sterilise a starch solution, for which process no directions are given, instead of preparing it afresh every time it is required.

A Scheme for the Detection of the more Common Classes of Carbon Compounds. By FRANK E. WESTON, B.Sc., F.C.S. London, New York, and Bombay: Longmans, Green, and Co. 1904.

This small book will be found very useful for many purposes, quite apart from the requirements of students preparing for the Final B.Sc. Examination of London, and the Honours Chemistry Examination of the Board of Education, for whose use it is specially intended. The student of organic chemistry will find his knowledge of his lecture work is more firmly established if he supplements it by working through the experiments described here, and investigators of problems in organic chemistry will possibly discover hints for the simplest method of identifying any organic compounds passing through their hands. The descriptions of some of the experiments require fuller details and more explanation of the reactions which occur, and the form into which the information is thrown gives the book some resemblance to the old type of rule-of-thumb qualitative analysis book. However, its use will certainly help the student to systematise his knowledge of the properties and reactions of many classes of organic compounds, and it should answer its purpose as a useful practical guide in preparing for the examinations mentioned.

Grundriss der Stereochemie. ("Outlines of Stereochemistry"). By Dr. A. HANTZSCH. Second Edition. Leipzig: Johann Ambrosius Barthel. 1904.

The first edition of this book, from which translations into French, English, and Russian were prepared, was issued in 1893, and the growth of our knowledge of stereochemistry since then has rendered advisable the publication of this second revised and enlarged edition, which, while preserving the form of the original, contains some new sections on the geometrically isomeric diazo-compounds and on stereo-isomerism in complex inorganic compounds. Recent developments in such branches as the relations between configuration and biological activity and the mutual transformations of optical antipodes are treated as fully as space allows, and in this form the book is a concise and useful introduction to larger text-books of stereochemistry.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 17, October 24, 1904.

Extraction of Vanadium from Naturally occurring Lead Vanadate, and the Preparation of certain Alloys of this Metal.—H. Herreschmidt.—The mineral, which came from the Santa Maria Mines in Spain, was smelted with coal and carbonate of soda in a reverberatory furnace. Metallic lead was formed, and a slag consisting of vanadate, aluminate, and silicate of sodium. To render this slag soluble in water, it was re-melted and air was blown into the melted mass until the vanadium was completely peroxidised. On treatment with water, 95 per cent of the vanadium present in the mineral went into solution. After precipitating out the silica, the solution was concentrated and the vanadic acid precipitated by means of sulphuric acid. For making ferro-vanadium by the electric furnace, the vanadium was precipitated from the purified solution of sodium vanadate by iron sulphate and sodium carbonate. An alloy of nickel and vanadium was made by reducing a mixture of nickel oxide and vanadic acid, the constituents being taken in the proportion necessary to obtain an alloy containing 25 per cent of vanadium.

A New Anhydride of Dulcitol.—P. Carré.—An anhydride of dulcitol can be obtained by heating this substance with phosphoric acid for some time at a temperature of 135°. The phosphoric ethers formed are saponified by water at 140°. The phosphoric acid is precipitated by baryta, the solution filtered and evaporated to a syrupy consistency. A thick yellowish liquid is obtained, which boils at 108° under a pressure of 18 m.m. Its formula by analysis is $C_6H_{10}O_4$. Various reactions prove that dulcitol contains two secondary alcohol groups, and hence its formula may be written $C_6H_6O_2(CHOH)_2$.

A New Method of Preparing Organic Derivatives of Phosphorus.—V. Auger.—White phosphorus is dissolved at 0° in alcoholic potash. This solution contains phosphorus in a low state of oxidation. On the addition of alkyl iodides, a phosphine, RPH_2 , a sub-oxide of phosphine, $(R.P)_2O$, and soluble phosphinous derivatives are obtained. This reaction seems to be of general application, since alkyl bromides and chlorides and other halogen derivatives, such as the monochloracetate of sodium, act in a similar fashion upon alkaline solutions of phosphorus.

Remarks upon a Recent Series of Calorimetric Determinations.—P. Lemoult.—The author has calculated the heat of combustion of thirty-five organic substances by means of a formula given in previous papers. He gives a table comparing his results with those recently obtained experimentally by Fischer and Wrede.

MISCELLANEOUS

Application of Permanganates to the Determination of the Constitution of the Amines and of other Ammonised Compounds.—A. Ginzberg.—The author proposed to determine, by means of permanganate, the presence of the non-saturated groups in the azotised compounds. As the amines reduce nearly the whole of this reagent after a longer or shorter lapse of time, it is best to commence by converting the substance under examination into benzene-sulphonised derivatives; these latter are only

oxidised in the cold by $KMnO_4$ when the amine contains an ethylenic function. In certain cases (an amine insoluble in water) it is advantageous to operate in a solution of acetate of ethyl, which dissolves to the extent of 1.5 per cent in $KMnO_4$, and which is not oxidised in the cold by this reagent. Experiments have been carried out on the benzene-sulphonised derivatives of the following amines:—Methylamine, fusible at 31°; dimethylamine, fusible at 47–48°; ethylamine, fusible at 57–58°; diethylamine, fusible at 42–43°; di-isobutylamine, fusible at 55–56°; aniline, fusible at 108.5–109°; methylaniline, fusible at 77.5–78°; ethylaniline, liquid; diphenylamine, fusible at 122–123°; piperidine, fusible at 92–93°; tetrahydroquinoline, fusible at 54–55°; and allylamine, fusible at 40.5–41°.—*Berichte*, vol. xxxvi., p. 2703.

Electric Conductivity of Solutions in Bromine.—V. A. Plotnikov.—Solutions in bromine of $AlBr_3$, either pure or treated with AlI_3 , do not act as electrolytes; on the other hand, solutions of the complex salts, $AlBr_3 \cdot CS_2$ and $AlBr_3 \cdot C_2H_5Br \cdot CS_2$, discovered by the author (*Bull. Soc. Chim.*, vol. xxvi., p. 605; and vol. xxx., p. 875), do conduct an electric current. Their conductivity has been examined by the Kohlrausch-Ostwald method between non-platinised electrodes (platinum black dissolves slowly in bromine). With $AlBr_3 \cdot CS_2$ the conductivity is almost nil if the solution contains only 2 or 3 per cent of the dissolved body; it increases, however, with the concentration, but diminishes rapidly on agitation, regaining its previous value when left to stand; finally, with concentrations of about 20 per cent it takes a definite value which is no longer affected by agitation; neither does it change with time; it is of the same order of value as that of aqueous solutions of ordinary salts; for example, the specific conductivity, K , of a 35 per cent solution = 0.0062. A solution of $AlBr_3 \cdot C_2H_5Br \cdot CS_2$ behaves like the preceding salt, but its conductivity is slightly higher. $SbBr_3$ is soluble in bromine, but its solutions are not good conductors; with saturated solutions (48 per cent of $SbBr_3$), $K = 98 \cdot 10^{-6}$. Dilute solutions of PBr_3 in bromine have a conductivity of almost nil, which, however, increases with the concentration; these solutions behave like those of the complex salts of $AlBr_3$; that is to say, their conductivity diminishes on agitation when they contain less than 13 per cent of PBr_3 ; with a saturated solution (36 per cent of PBr_3), $K = 0.0534$.—*Journ. Soc. Phys. Chim. R.*, vol. xxxv., p. 794.

Action of the Halogen Derivatives of the Tri- and Penta-valent Metalloids upon Alkyl Halogen Compounds.—V. Auger.—By the reaction of Crafts and Silva the iodide of triethyl phosphine is easily obtained by acting upon white phosphorus with ethyl iodide. The author has shown that if the constituents are taken in the proportion of P_2I_4 to 3RI, the most abundant product of the reaction is a dialkyl phosphinic derivative, mono- and tri-derivatives being formed at the same time. A larger proportion of the mono-derivative is formed if less alkyl iodide is used. Attempts to prepare similar compounds from the halogen derivatives of antimony, arsenic, and bismuth were unsuccessful.—*Comptes Rendus*, cxxxix., No. 18.

The Density of Nitrogen Monoxide and the Atomic Weight of Nitrogen.—A measured volume of nitrogen monoxide was absorbed in a tube containing carbon. The tube was surrounded by a mixture of solid CO_2 and ether. The increase in weight of the tube gives the weight of gas absorbed. The mean of three experiments gives 1.97788 as the weight of a normal litre of the gas. The molecular weight of the gas, determined by applying the theorem of corresponding conditions, and comparing its density with that of carbon dioxide, was found to be 46.026. This gives 14.013 as the atomic weight of nitrogen. From this and from other experiments, which give 14.011 as the mean value of the atomic weight, it seems that the value ($N = 14.04$) given in the International Table for 1904 is rather too high.—*Comptes Rendus*, cxxxix., No. 18.

Chemical Society Research Fund.—A meeting of the Research Fund Committee will be held in December next. Applications for grants, to be made on forms which can be obtained from the Assistant Secretary, must be received on or before Monday, December 5, 1904.

MEETINGS FOR THE WEEK.

MONDAY, 28th.—Society of Arts, 8. (Cantor Lectures). "Musical Wind Instruments," by David James Blaikley.
WEDNESDAY, 30th.—Society of Arts, 8. "The British Canals Problem," by Arthur Lee, J.P.
THURSDAY, Dec. 1st.—Chemical, 8. "The Nitrates of the Alkali Metals and Metals of the Alkaline Earths, and their Decomposition by Heat," by P. C. Ray.

HACKNEY INSTITUTE, DALSTON LANE, N.E.

The Governing Body require the services of an ASSISTANT LECTURER in the CHEMISTRY DEPARTMENT on two evenings per week. Fee, 15s. per evening of two and a-half hours.
Application, with testimonials, to be sent to the SECRETARY, not later than NOVEMBER 30th, 1904.

CENTRAL TECHNICAL SCHOOLS FOR CORNWALL, TRURO.

The Committee requires an ANALYTICAL CHEMIST with a sound knowledge of Agriculture. Capable of teaching; and also to assist the Principal, Professor CLARK. The Appointment is for one year, but may become permanent. Salary £200. Further particulars may be obtained from the Secretary.—Applications, with testimonials, should be sent not later than NOVEMBER 29th.

Princes Street, Truro,
November 15, 1904.

A. BLENKINSOP, Secretary.

VOL. XC., No. 2349.

AN ATTEMPT TO EXPLAIN THE OCCURRENCE OF ZINC, CADMIUM, AND MERCURY IN THE SAME GROUP WITH THE ALKALINE EARTHS. AND OF TIN AND LEAD IN THE CARBON GROUP, AND OF COPPER, SILVER, AND GOLD IN THE SAME GROUP WITH THE ALKALINE METALS.

By E. W. WETHERELL, A.R.C.S.

In my previous paper (CHEMICAL NEWS, vol. xc., p. 260, November 25, 1905) on the anomalies of beryllium, argon, and tellurium, I suggested that the irregularities might be due to the presence of satellites to the atoms of those elements, and for that purpose I drew up a table which showed that every element of groups 0, 2, 4, and 6 was a direct multiple of 4, or that it lay between the limits of the two multiples of 4 which happened to lie in the same space. I now find that the elements which have almost exact multiples of 4 are more typical of their groups than those which lie between two multiples, and it has therefore appeared to me that it is possible that only one multiple can occur in any one space, and that the deviation of an element is due in other cases to the presence of a satellite. I find by calculations that the lowest multiple of 4 for zinc is 64, for cadmium 108, and for mercury 196 (*vide* table in previous article); these atomic weights would require such relatively large satellites to bring them up to their experimental value that the peculiar properties of these metals (which distinguish them from the alkaline earths) may be due to satellites. If these elements had no satellites their true atomic weights would be 64, 108, and 196 respectively, and these elements, α -zinc, α -cadmium, and α -mercury, would be alkaline earths. In this connection I may mention that the possible satellite of barium is only 1.2, which is so small relatively to the weight of α -barium, that it has little effect on the characters of barium. It seems to me not an impossibility that these satellites have some action in preventing the linking of the atoms of Zn, Cd, and Hg in the free state, for it is well known that these three metals are monatomic.

To turn to the carbon group. It is patent to the most casual observer that tin and lead stray far from the typical elements of the carbon group in many of their characters. I find, on the multiple of 4 theory, that all the other members of the carbon group can have no satellites (or very small ones), but that as tin and lead should have atomic weights of 116 and 204 respectively that they must have comparatively large ones. In this case, again, the satellite has the effect of making the elements more metallic, more easily reducible, and less ready to be acted upon by the atmospheric agents.

In the case of copper, silver, and gold their atomic weights should be 60, 104, and 192 respectively; consequently, large satellites are necessary to bring these values up to the weights determined by experiment; here again the effect of the satellites has been to render these elements less alterable.

If the table of the Periodic Law holds good, there should be analogues of copper, zinc, and tin in the interval between cerium and tantalum; it should be easy to calculate their "planet and satellite" values in the following way:—The difference between "planetary" copper and "planetary" silver is 44, and between "planetary" silver and "planetary" gold is 88; consequently, the analogue will be 44 more

than silver and 44 less than gold; this will give the value for the "planet" of 148. Such an element without a satellite would be an analogue of sodium; but it is much more probable that it will have a satellite of about the value of 4; it will then be a metal not acted upon by atmospheric oxygen, only slightly acted upon by sulphur vapours, occurring native in minute quantities (probably associated with gold and silver), crystallising in the cubic system, and having an atomic weight which experiment will show to be 150—153.

The same rule of intervals of 44 occurs between "planetary" zinc 64 and "planetary" cadmium 108, and the same interval of 88 between "planetary" cadmium and "planetary" mercury; hence the calculation for the analogue is the same. If the element has an atomic weight of 152 it will have the characters of magnesium, but if the "satellite" is present it will be close to cadmium in its properties, but probably even less alterable. It will probably be found to have an atomic weight of 156.

The interval between "planetary" tin and "planetary" lead is again 88, and the missing analogue should have an atomic weight of 160, and if no satellite is present it will resemble silicon. If a satellite of about the value of 3 is present the atomic weight will be 163, and the characters will be analogous to tin and lead.

Government of Mysore, India.

THE ABSORPTION OF HYDROGEN BY RHODIUM. By L. QUENNESSEN.

In the course of researches on metals allied to platinum, I have been led to modify certain properties mentioned by former writers.

Thus, according to Th. Wilm (2), pure rhodium should possess a capacity of absorbing hydrogen much greater than that of platinum, and this assertion is reproduced to-day in different works. Wilm further announced that this absorptive property varied with the method of preparation of the metal; for example, that the rhodium obtained by calcination of the double chlorammonium salt had a higher absorbent power than the metal obtained with the double chloride of sodium or of potassium, and that this absorption was apparently due to a chemical affinity of the metal for hydrogen.

My experiments in no wise confirm these facts.

Some rhodium, mixed with sodium chloride, fused and powdered, was treated with a current of chlorine at 440°; then, in order to remove the impurities which might remain, the product was taken up with water and converted into the double nitrite of rhodium and sodium. The latter salt was divided into two portions; one was re-converted by hydrochloric acid into the double chloride of sodium and rhodium, and the other into the double chloride of rhodium and ammonium, this being obtained perfectly pure by treating the double nitrite of sodium with ammonium chloride in order to make the double ammoniacal nitrite and the latter by hydrochloric acid.

These two compounds were then heated and reduced at a red heat in a current of pure dry hydrogen, in which the rhodium was allowed to cool.

In the case of the double salt of sodium, the precaution was also taken of removing the alkaline chloride by washing with warm water and repeating the hydrogen treatment under the same conditions.

If, after cooling is complete, the tube containing the boat with the rhodium is opened, one detects, with the entrance of air, the simultaneous formation of water vapour, which condenses on the glass, whilst, if the atmosphere of hydrogen is expelled by a current of pure dry carbon dioxide, the phenomenon of formation of water upon contact with the air is not produced.

Further, if the boat with the rhodium is placed in a vacuum and heated to 440° by means of the sulphur bottle, the barometric column attached to the apparatus indicates no variation of pressure, and it is quite impossible to extract from it the least bubble of gas by means of the mercury tube.

These experiments, repeated at different times, always gave the same result; they therefore lead to the conclusion that rhodium is not analogous to palladium as regards chemical affinity for hydrogen, and that it acts as would platinum, condensing oxygen and hydrogen to form water.

Further, it does not appear that the rhodium obtained by decomposition of the chlorammonium salt has properties much more active than that obtained by decomposition of the sodium chloride salt when the latter has been freed by washing from the alkaline chloride which envelopes it.

THE REFRACTIVE INDICES OF THE ELEMENTS.*

By CLIVE CUTHBERTSON.

IN a letter addressed to *Nature* in October, 1902, attention was drawn to the fact that the refractivities of the five inert gases of the atmosphere, He, Ne, A, Kr, and X, as determined by Ramsay and Travers, were, within narrow limits of accuracy, in the proportion of 1, 2, 8, 12, and 20; or, more simply, of $\frac{1}{4}$, $\frac{1}{2}$, 2, 3, and 5.

In a second letter it was shown that the refractivities of the halogens, Cl, Br, and I, stand also in the relation of 2, 3, and 5 to the same degree of accuracy; but it was pointed out that the figures for P, As, and S, as measured by M. Le Roux in 1861, did not show any similar relation; and it was observed that a re-determination of them would be interesting.

With a Jamin's refractometer, adapted for use with high temperatures, results have now been obtained for Hg, P, and S, which differ widely from those of M. Le Roux. The index of mercury, calculated for a molecule containing two atoms, is placed at 1.00857, a number which agrees closely with the value given by the refractive equivalent of Gladstone. The index of P₂ is found to be 1.001197 and that of S₂ is 1.001010.

In all three cases it is estimated that the margin of error does not exceed $\frac{1}{4}$ per cent. Comparing these values for P₂ and S₂ with those of N₂ and O₂, it is shown that the simple relations found in the case of the inert gases and the halogens also hold in the case of nitrogen and phosphorus, oxygen and sulphur; and that an atom of phosphorus retards light four times as much as an atom of nitrogen, an atom of sulphur four times as much as an atom of oxygen.

Efforts have also been made to measure the index of fluorine in the gaseous state, but, owing to the experimental difficulties, success has not yet been attained.

It appears then, that, out of fourteen elements whose index of refraction has been measured in the gaseous state, twelve conform to the rule that in each chemical group the refractivities of the elements are in the ratios of small integers. The other two, Hg and H, have no allied elements with which they can be compared.

It is pointed out that N, O, and Ne are each followed, in their respective families, by an element whose refractivity is four times as great, and that, consequently, there are reasons for believing that the elements composing the series N, O, F, and Ne, and P, S, Cl, and A, are in some sense homologous. Comparing the refractivities of the latter series we see that the power to retard light appears to be closely connected with the valency, increasing as it increases, in spite of the decrease in atomic weight as shown in the following table:—

	Element.			
	P.	S.	Cl.	A.
Atomic weight ..	31	32	35.5	40
Refractivity ..	299×4	275×4	192×4	141×4

The series Ne, O, N, show the same relation, and it is probable that the refractivity of C is even higher than that of N.

The refractivity of B, estimated from BCl₃ and BBr₃, is certainly very great; but whether it exceeds that of C there is not sufficient evidence to determine.

HYDRONITRIC ACID AND THE INORGANIC TRINITRIDES.*

By L. M. DENNIS and A. W. BROWNE.

THE following paper contains:—I. A brief historical review of the work published up to the present time upon hydronitric acid and the inorganic trinitrides. II. An experimental study of (A) the method of W. Wislicenus for preparing hydronitric acid, (B) the composition of certain inorganic trinitrides, (C) a method for the detection of hydronitric acid and inorganic trinitrides, and (D) the reaction between hydronitric acid and potassium permanganate in the presence of sulphuric acid.

I. HISTORICAL.

Under this head will be considered—(1) The methods of preparing hydronitric acid, (2) the inorganic compounds of hydronitric acid and the methods of preparing them, and (3) the properties and reactions of hydronitric acid and the inorganic trinitrides. The organic derivatives will be considered in the present work only in so far as they are of interest in the preparation of the acid.

At the outset it may be well to discuss the question of nomenclature. A variety of names for the acid and its derivatives have been used by English and American investigators and writers. The name *azimide* has perhaps been most frequently used to designate the acid. This has the disadvantage of neither expressing the acid character of the compound nor indicating its close analogy to the halogen hydrazides. Among other names which have been used are *hydrazotic acid* (*Journ. Chem. Soc.*, lxxvii., 705); *triazotic acid*, derivatives called respectively *azides* and *triazates* (H. C. Jones, "Principles of Inorganic Chemistry," p. 208, the Macmillan Company, New York, 1903); *hydronitrous acid* (Mendeleeff's "Principles of Chemistry," 2nd English edition by Kamensky and Lawson, vol. i., p. 265, Longmans, Green, and Co., London, 1897); *hydrogen nitride* (*Journ. Chem. Soc.*, [1], lx., 56, 524); and *nitrogen hydride* (*Journ. Chem. Soc.*, [1], lx., 394).

In the publications from the Cornell University Laboratory the term hydronitric acid has been employed for the following reasons:—

In English usage the prefix "hydro" connotes the absence of oxygen, and acids bearing this prefix have also the termination "ic." The name employed is derived from nitrogen instead of azote, for the reason that while both are of Greek origin, nitrogen is distinctly a word of English usage, while azote is still to be regarded as a foreign word that has not yet received adoption into our language. Following the analogy between the term hydronitric acid and the names of the halogen acids, such as hydrochloric acid, the salts of hydronitric acid would normally be termed nitrides, but a distinct group of nitrides—of which potassium nitride, K₃N, may be cited as an example—has long been known. Consequently, the term "trinitride" was adopted to distinguish the salts of hydronitric acid from this other group of nitrides, and the termination "ide" is employed to show that the compounds contain no oxygen. In further recognition of the analogy between

* Abstract of a Paper read before the Royal Society, November 24, 1904.

* From the *Journal of the American Chemical Society*, xxvi., No. 5.

the trinitrides and halides, it is suggested that the ring of three nitrogen atoms be called the nitrine group, and that the hypothetical compound, $(N_3)_2$, analogous to the chlorine, bromine, or iodine molecule, be called nitrine.

1. Methods for Preparing Hydronitric Acid.

The methods employed by various investigators in the preparation of hydronitric acid may be classified under five heads:—

a. Methods involving the action of a compound containing a chain of two nitrogen atoms united to positive atoms or radicals upon a compound containing a single nitrogen atom united to negative atoms or radicals.

b. Methods involving the action of a compound containing a chain of two nitrogen atoms united to negative atoms or radicals upon a compound containing a single nitrogen atom united to positive atoms or radicals.

c. Methods involving the simultaneous oxidation of two compounds, one of which contains a chain of two nitrogen atoms, the other a single nitrogen atom, and both of which are united to positive atoms.

d. Methods involving the decomposition of a compound containing a chain of three or more nitrogen atoms.

e. Methods involving the hydrolysis of aromatic derivatives of hydronitric acid.

A possible new class of methods, which has received as yet no experimental attention, is the converse of c. This class will include methods involving simultaneous reduction of two compounds, one of which contains a chain of two nitrogen atoms, the other a single nitrogen atom, and both of which are united to negative atoms.

a. The reactions involved in the methods under this head may, in their simplest form, be expressed by the typical equation $NH_2.NH_2 + NO_2H = HN_3 + 2H_2O$.

The now classical experiments which led Curtius (*Ber.*, xxiii., 3023), in 1890, to the discovery of hydronitric acid, consisted in the preparation of benzoyltrinitride by the action of nitrous acid upon benzoylhydrazine.

By saponifying the benzoyltrinitride with sodium hydroxide he obtained sodium trinitride, from which he was able to prepare free hydronitric acid by distillation with sulphuric acid.

Subsequently he used, instead of sodium hydroxide, sodium ethylate (*Ber.*, xxiv., 3341) and alcoholic ammonia (*Ber.*, xxix., 759).

In 1893 Curtius (*Ber.*, xxvi., 1263) found that a dilute aqueous solution of hydronitric acid could be obtained by leading the red gases evolved from a mixture of nitric acid and arsenic trioxide into a dilute ice-cold solution of hydrazine hydrate, or by adding the blue solution obtained by condensing the red gases upon ice. This method he considered particularly adapted for lecture-room purposes.

At about the same time, Angeli (*Attd. Reale Accad.*, [5], ii., 1, 569; *Centrbl.*, 1893, ii., 559) prepared silver trinitride by adding a solution of hydrazine sulphate to a cold saturated solution of silver nitrate.

Dennstedt and Göhlich (*Chem. Zeit.*, xxi., 876), in 1897, described the preparation of hydronitric acid by the interaction of hydrazine sulphate and potassium nitrite.

In 1899 Sabanejeff and Dengin (*Zeit. Anorg. Chem.*, xx., 21) found that by gently heating in a test-tube a mixture of 1.5 grms. of hydrazine sulphate and 4 c.c. of nitric acid (density 1.3), they could obtain hydronitric acid as one of the reaction products. The yield amounted to from 10 to 12 per cent of the hydrazine sulphate used. The method is recommended by its author as an especially available one for lecture-room work.

In the same year, Tanatar (*Ber.*, xxxii., 1399) devised a method for preparing hydronitric acid by the action of nitrogen trichloride upon hydrazine.

b. The reaction typical of this class of methods may be expressed by the equation $NH_3 + N_2O = NH_3 + H_2O$.

W. Wislicenus (*Ber.*, xxv., 2084) stated in 1892 that he was unable to prepare the acid by direct union of the two substances, but that its sodium salt could be obtained by

passing dry nitrous oxide over sodium amide heated to a temperature of between 150° and 250°.

A detailed experimental study of the method of Wislicenus will be found below.

c. The typical reaction for this class of methods is expressed by the equation—

In 1902 Tanatar found that when a molecular mixture of hydrazine and hydroxylamine salts was oxidised in acid solution by bromine water, permanganic acid, lead dioxide or red lead, a small quantity of hydronitric acid was invariably formed. With hydrogen peroxide a yield of 24.3 per cent, and with chromic acid a yield of 29.27 per cent was obtained (*Ber.*, xxxv., 1810).

d. In 1892 Thiele (*Lieb's Ann. Chem.*, cclxx., 1) obtained hydronitric acid by decomposing the salts of diazoguandine.

Freund and Schander (*Ber.*, xxix., 2500) obtained hydronitric acid by the action of an alkali upon aminotriazasulphol,—

It will be seen that both methods thus far considered under this head may be looked upon as involving the decomposition of compounds that are derivatives of the hypothetical compound of hydrogen and nitrogen, $NH_2.H:NH$.

In the opinion of Hantzsch and Vogt (*Lieb's Ann. Chem.*, cccxiv., 339), however, the so-called diazoguandine is not to be regarded as a real diazo-compound, but as a trinitride with this structure:—

The method of Angeli, given above, might be regarded as a member of this class of methods if the possible formation of the intermediate product is considered of any importance.

In 1893 Curtius (*Ber.*, xxvi., 1263) found that, by the action of certain diazo-compounds upon hydrazine or certain of its primary substitution products, he in all probability obtained derivatives of the hypothetical compound of hydrogen and nitrogen, $NH_2.NH.N:NH$, which he called butylene.

e. Methods of obtaining hydronitric acid by the hydrolysis of aromatic trinitrides are perhaps not of the same theoretical interest as those described above, as the former start from compounds already containing the nitrine group, and prepared by some other method. Work done upon the subject has, however, brought out still further the interesting analogy between the trinitrides and the chlorides, by showing that the replaceability of the nitrine group, as well as of the chlorine atom, is increased by the introduction of certain groups into the benzene ring.

As illustrative of methods of this class, the work of Nöling and Grandmougin (*Ber.*, xxiv., 2546), and of Nöling, Grandmougin, and Michel may be cited (*Ber.*, xxv., 3328).

Later, Michel (*Moniteur Scientifique*, [4], vii., II., 749) extended the experiments of the above mentioned investigators, and confirmed the conclusion already indicated by them, that aromatic trinitrides containing negative radicals in the ortho- or para-position may be hydrolysed by the action of alcoholic potassium hydroxide, while the meta-substitution products do not so react.

In so far as any attempt has been made by different authors to compare the above methods for preparing hydronitric acid on the basis of practical utility, the almost unanimous verdict seems to be that the method of Wislicenus is on the whole the most satisfactory. One

reviewer speaks of the nitrogen trichloride method of Tanatar as the one next to be preferred (Harden, *Journ. Chem. Soc.*, lxxvi., II., 479).

2. Inorganic Compounds of Hydronitric Acid.

In 1890, Curtius (*Ber.*, xxiii., 3023) briefly described the trinitrides of silver AgN_3 , mercury Hg_2N_6 , and barium BaN_6 . He also mentioned the existence of the ferrous, cuprous, sodium, and ammonium trinitrides. In 1891 (*Ber.*, xxiv., 3341), he further described some of the same compounds, and also the trinitrides of lead and diammonium, $\text{N}_2\text{H}_5\text{N}_3$.

In 1896, Dennis and Doan (*Journ. Am. Chem. Soc.*, xviii., 970) prepared thallous trinitride, TlN_3 , and thallous-thallic trinitride, $\text{TlN}_3\cdot\text{TlN}_3$.

In 1898 Dennis and Benedict (*Journ. Am. Chem. Soc.*, xx., 225; *Zeit. Anorg. Chem.*, xvii., 18), in the course of a general investigation upon the trinitrides of the alkali and alkaline earth metals, prepared the trinitrides of lithium $\text{LiN}_3\cdot\text{H}_2\text{O}$, sodium, potassium KN_3 , rubidium RbN_3 , and caesium CsN_3 , and the trinitrides of calcium CaN_6 , strontium SrN_6 , and barium $\text{BaN}_6\cdot\text{H}_2\text{O}$.

In the same year Curtius and Rissom (*Journ. Prakt. Chem.*, [2], lviii., 261) prepared the following compounds:—Ammonium, lithium LiN_3 , sodium, potassium, rubidium, caesium, thallium, calcium, strontium, barium, diammonium, cadmium CdN_6 , pyridine cadmium $(\text{C}_5\text{H}_5\text{N})_2\text{N}_6\text{Cd}$, and cupric CuN_6 trinitrides; also basic trinitrides of zinc $\text{ZnN}_3\cdot\text{OH}$ (?), manganese $\text{MnN}_3\cdot\text{OH}$, nickel $\text{NiN}_3\cdot\text{OH}$ (?), cobalt $\text{CoN}_3\cdot\text{OH}$, and chromium (ratio $3\text{Cr} : 2\text{N}_3$); and double trinitrides of cobalt and potassium $\text{CoN}_6\cdot\text{KN}_3$, cobalt and ammonium $\text{CoN}_6\cdot\text{N}_4\text{H}_4$, and of nickel and potassium $\text{NiN}_6\cdot\text{KN}_3$ (?). He did not succeed in isolating the trinitrides of magnesium, beryllium, iron, aluminum, platinum, and gold.

In 1900, Curtius and Darapsky (*Journ. Prakt. Chem.*, [2], lxi., 408), in continuation of the work just described, made a further study of the behaviour of aluminum, iron, and chromium toward hydronitric acid. They found that solutions of alums of these elements reacted with sodium trinitride in a manner similar to that described for thorium by Dennis and Kortright (*Zeit. Anorg. Chem.*, vi., 35; *Am. Chem. Journ.*, xvi., 79), and by Dennis (*Journ. Am. Chem. Soc.*, xviii., 947), who found that thorium is quantitatively precipitated from solution by the addition of potassium trinitride on boiling. These three elements, as well as the thorium, separate under this treatment in the form of hydroxides. A new basic trinitride of chromium (ratio, $\text{Cr} : \text{N}_3$) was prepared. Zirconium was found to be precipitated quantitatively as hydroxide, even in the cold, by the addition of sodium trinitride to a solution of zirconium sulphate. With yttrium, lanthanum, cerium, and didymium they obtained basic salts in which two nitride groups were joined to each atom of the element in question. By boiling a solution of uranyl nitrate after treatment with sodium trinitride they effected a quantitative separation of uranyl hydroxide. Using the method of precipitation with alcohol and ether, they confirmed the results of Curtius and Rissom by preparing the basic trinitride of manganese, and also prepared the neutral trinitride of nickel, $\text{NiN}_6\cdot\text{aq}$. Attempts were made to isolate the trinitrides of arsenic and antimony, but without success.

In 1900, Hantzsch (*Ber.*, xxxiii., 522) prepared a trinitride of iodine, IN_3 , by the action of a solution of iodine in benzene or ether upon silver trinitride.

A crystallographic study of several of the inorganic trinitrides was made by Gill (*Journ. Am. Chem. Soc.*, xx., 225; xviii., 970; *Zeit. Anorg. Chem.*, xvii., 18) and by Rosenbusch (*Journ. Prakt. Chem.*, lviii., 261; *Z. Krystall.*, xxxiii., 99).

Curtius and his students have prepared a large number of the compounds of hydronitric acid with organic acids, the compound carbonyl trinitride (carbazine), $\text{CO(N}_3)_2$, is of especial interest to the inorganic chemist because of its analogy to carbonyl chloride. Curtius (*Ber.*, xxvii., 2684) prepared this compound by the action of sodium nitrite

upon the hydrochloric acid salt of carbonyl hydrazide, $\text{CO(NH.NH}_2\cdot\text{HCl)}_2$. Pommerehne (*Arch. Pharm.*, cxxxvi., 479) has prepared several compounds of hydronitric acid with organic bases. For information with respect to these compounds, and for further details concerning the inorganic compounds mentioned above, the reader is referred to the original papers, or to the recent work of Dr. Leopold Spiegel, "Der Stickstoff und Seine Wichtigsten Verbindungen."

(To be continued.)

SILICA DETERMINATIONS.

By HARRISON EVERETT ASHLEY,
Chemist Homer Loughlin China Co.

THE recent discussion of the need of two evaporations to dryness in order to separate silica completely from solution has had reference to two classes of solutions:—

Class I.—The acidified extract of an alkaline fusion (the most general case).

Class II.—The acid solution of a completely soluble silicate mixture (cements).

In iron-ore analysis, as frequently practised, two further cases occur.

Class III.—The hydrochloric acid extract of the ore leaves a portion of the silica as an insoluble residue.

Class IV.—The hydrochloric acid extract of the ore leaves all of the silica as an insoluble residue.

The extract of Class III. must be evaporated to dryness and filtered, once or twice according to the amount of soluble silica and the skill of the analyst. The additional silica so obtained is put with the original insoluble residue, ignited, and weighed, then corrected by evaporation with hydrofluoric and sulphuric acids, ignition and weighing. If desirable, the non-volatile residue may be fused with a very small amount of sodium carbonate, and added to the main extract.

The silicious residue in the Class IV. may be at once ignited and weighed, and the gross weight corrected by treatment with hydrofluoric and sulphuric acids. Thus, an ore that is found to fall in this class requires no evaporation to dryness for the silica determination.

The procedures in these two last cases save much time, and keep down the amount of sodium salts in solution.

I have treated high grade limestones similarly. After dissolving in hydrochloric acid, evaporating to dryness, taking up with hydrochloric acid, and filtering, and repeating this procedure, about one-half the insoluble residue is silica. Mr. S. V. Peppel, formerly of the Ohio Geological Survey, informs me that some time ago, in seeking a rapid commercial method, he attempted to apply the process to lower grade limestones, but found the loss of weight with the hydrofluoric and sulphuric acid treatment greater than the amount of silica present.—*The Chemical Engineer*, No. 1, November, 1904.

Preparation of Aurous Iodide by the Action of Iodine on Gold.—Fernand Meyer.—At ordinary temperatures pure and dry iodine has no action upon gold, and aurous iodide does not decompose in a vacuum. Between 50° and its melting-point pure and dry iodine does combine with gold with the production of amorphous iodide. At the melting-point of iodine, and above, crystallised aurous iodide is obtained. The direct action is always limited by decomposition of the iodide obtained; but the latter can be obtained pure by using excess of iodine and separating the iodine from the iodide by heating to 30° . In the presence of water, in a closed vessel, iodine and gold form aurous iodide; but if the iodine can escape, aurous iodide is completely decomposed by water or damp air.—*Comptes Rendus*, cxxxix., No. 19.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Ordinary Meeting, Thursday, November 3rd, 1904.

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

(Concluded from p. 265).

173. "Note on the Influence of certain Salts and Organic Substances on the Oxidation of Guaiacum." By Miss EDITH GERTRUDE WILLCOCK.

The author has investigated the influence of various salts on the oxidation of guaiacum with hydrogen peroxide by determining the time necessary to produce a standard blue tint when the conditions were so adjusted that the concentration of guaiacum, peroxide, and salt, and the temperature were the same throughout the series.

It was found that the oxidation was accelerated by the chlorides of ammonium, lithium, potassium, barium, iron, and aluminium, the bromides of sodium and potassium, potassium iodide, sodium fluoride, and potassium nitrite; whereas the nitrates of ammonium, potassium, and barium, and the sulphates of sodium, potassium, and magnesium had no appreciable influence.

These results show (1) that the influence of the salt is determined by the nature of the anion, and (2) that the halogen salts as a group accelerate the oxidation.

Of the salts examined, those of the halogens alone showed a true accelerating action, for although potassium nitrite certainly accelerates the oxidation of guaiacum by hydrogen peroxide, yet as it will itself oxidise this resin in the absence of the peroxide its influence is not comparable with that of the salts which have no independent oxidising action; this remark also applies to ferric chloride.

A comparison of the salts of the halogens among themselves showed that the iodides have the greatest accelerating action, the effect of the others diminishing in the following order, namely, bromides, chlorides, and fluorides. The position of the iodides in the list may be connected with the oxidising action of hydrogen peroxide on these salts.

Salts, such as aluminium chloride and sodium fluoride, which form acid solutions, have a relatively feeble accelerating power.

Ordinary "pure" aluminium chloride readily oxidises guaiacum even in the absence of peroxide, but a specially purified sample of the salt had no independent oxidising action whatever, and it increased the rate of oxidation by hydrogen peroxide only very slightly. The activity of commercial aluminium chloride is probably due to the presence of ferric chloride.

The acids of the acetic series have no accelerating action, but the metallic salts of the lower members of the series have a slight influence, due probably to the fact that they are hydrolysed by water into free acid and base. Carbohydrates and proteids have no action.

Formaldehyde is commonly described as oxidising guaiacum, but this effect is probably due to impurities. The commercial product is an active oxidiser, turning guaiacum blue even in the absence of hydrogen peroxide, but pure formaldehyde, freshly prepared by the distillation of paraformaldehyde, has no action whatever.

Commercial glycerol readily oxidises guaiacum, turning the resin blue immediately, but in this case also the action seems to be due to impurities, for when freshly distilled under diminished pressure in the dark it has no effect by itself, although, like methyl and ethyl alcohols and ethylene glycol, it assists the accelerating action of the metallic haloids at the ordinary temperature (15–25°). These substances, however, at 50–70° all exert a retarding influence, and this may be due to some absorption of the available oxygen by the alcohol.

The carbohydrates dextrose, lævulose, sucrose, maltose, dextrin, starch, glycogen, and mastic decrease the

accelerating action of the salts, and the proteid globulin has the same action.

The action of carbohydrates and proteids (globulins) in diminishing the accelerating power of salts is probably due to the fact that the organic substance, being itself oxidisable, absorbs a part of the oxygen which is liberated, and also to its influence on the degree of dissociation of the salt (compare Walker and Hamby, *Trans.*, 1897, lxxi., 61).

The effect of sucrose on the electrical conductivity of sodium chloride has been measured by Mr. Hardy, who found that the presence of 16 per cent of this sugar in a normal solution of the salt diminished the electrical conductivity by 23 per cent (compare *Journ. Physiol.*, 1903, xxix., 26).

The accelerating action of the alcohols is adequately explained by their influence on the solubility of the guaiacum. When an alcoholic solution of the resin is added to water, precipitation occurs, but on the addition of more of the alcohol the precipitate re-dissolves. This was found to be the case with all the alcohols examined except mannitol, and this substance alone failed to accelerate the oxidation of the guaiacum.

174. "Note on the Influence of Potassium Persulphate on the Estimation of Hydrogen Peroxide." By JOHN ALBERT NEWTON FRIEND.

It was shown in a recent communication (*Trans.*, 1904, lxxxv., 597) that in ordinary circumstances a correct estimate of hydrogen peroxide is not obtained by titration with potassium permanganate. The author now shows that for every molecule of peroxide not accounted for a molecule of persulphate disappears. This observation suggests that the reaction $H_2O_2 + K_2S_2O_8 \rightarrow K_2SO_4 + H_2SO_4 + O_2$ probably takes place, this change being catalytically accelerated by some oxide of manganese formed during titration.

175. "The Influence of Sunlight on the Dissolution of Gold in Aqueous Potassium Cyanide." By WILLIAM ARTHUR CALDECOTT.

The fact that the formation of potassium thiocyanate in aqueous solution, under the conditions indicated by the equation $PbS + KCy + O \rightarrow PbO + KCNS$, is accelerated by bright sunlight, was noted some years ago by Bettel and Feldtmann (*Proc. Chem. Metallurg. Soc. S. Africa*, 1896, i., 267). In a paper published last year (*Journ. Chem. Metallurg. Soc. S. Africa*, 1903, iv., 51) by E. H. Johnson and the author, the analogy between potassium aurocyanide and potassium thiocyanate with regard to their formation and reduction was discussed.

The following experiments were carried out with the view of ascertaining whether sunlight accelerated the formation of potassium aurocyanide, as well as that of potassium thiocyanate.

A strip of gold foil weighing 832.5 milligrams, and having a total superficial area of 852 sq. m.m. was immersed in a 0.5 per cent potassium cyanide solution, contained in a clear glass litre bottle at about 19°. In another similar glass vessel, coated with three layers of black varnish, was placed a corresponding amount of the potassium cyanide solution and a strip of gold foil weighing 900 milligrams, but with a superficial area equal to that of the other strip. The two bottles were then exposed to direct sunlight for about five and a-half hours daily during five days, the loss of weight of the gold foil strips was noted, the maximum temperatures of the solutions being recorded daily. The results were as follows:—

	The clear bottle.		The blackened bottle.	
	Gold dissolved in milligrams.	Temp.	Gold dissolved in milligrams.	Temp.
1st day ..	25.5	30	20.0	40
2nd day ..	21.0	34	17.0	38
3rd day ..	28.0	34	20.0	38
4th day ..	27.0	37	17.0	40
5th day ..	32.0	30	19.0	43
Daily average ..	26.7	36	18.6	39.8

This table shows that the rate of dissolution of the gold in the clear glass bottle was 43 per cent greater than that in the blackened vessel, although the temperature of the solution was on an average 3.8° lower than in the former case.

The lately published researches of Berthelot (*Comptes Rendus*, 1904, cxxix., 169) indicate that the absorption of oxygen by aqueous potassium cyanide is accelerated by sunlight. The greater rapidity with which gold dissolves in potassium cyanide solution in bright sunlight may hence be considered as being due to the liberation of more nascent cyanogen, in proportion to the additional oxygen absorbed, with the consequent increased formation of aurous cyanide.

176. "The Fractional Hydrolysis of Amygdalinic Acid, *iso*-Amygdalin." By HENRY DRYSDALE DAKIN.

As amygdalinic acid, prepared by the action of hot baryta solution on amygdalin, gives racemic mandelic acid on complete hydrolysis with acids, it is therefore probably a partially racemic substance, and may be considered as being the maltoside of inactive mandelic acid. On fractional hydrolysis, it was found that the mandelic acid set free in the earlier stages of the reaction was strongly dextrorotatory, whilst that liberated at a later stage was levorotatory. By repeated crystallisation of the magnesium salts and of the free acids derived from the products of hydrolysis, it was found possible to isolate both optically active varieties of mandelic acid in a pure state.

Starting from amygdalin, which on hydrolysis gives *l*-mandelic acid almost exclusively, it is thus possible to prepare both *d*- and *l*-mandelic acids without employing any additional optically active substance.

The production of an isomeric partially racemic amygdalin, as the result of the limited action of baryta solution on amygdalin, was suggested by J. W. Walker (*Trans.*, 1903, lxxxiii., 472), but efforts to isolate the substance were unsuccessful.

The substance has now been obtained in crystalline form, and its main properties have been investigated; it is very much more soluble in water and alcohol, has a much lower melting point, and a higher specific rotation than ordinary amygdalin. The close relationship between the two substances is shown by the fact that both are similarly attacked by the enzymes, emulsin and maltase.

The new substance gives amygdalinic acid and ammonia on treatment with alkali, whilst with concentrated acids it yields mandelic acid, glucose, and ammonia. The mandelic acid set free on complete hydrolysis with hydrochloric acid is distinctly dextrorotatory, whereas that derived from ordinary amygdalin is levorotatory. The suggested cause of this surprising result is that the two forms of which *iso*-amygdalin, as a partially racemic substance, may be assumed to be composed are hydrolysed at unequal rates, and that the form which is least readily hydrolysed undergoes progressive racemisation.

177. "The Effect of Anhydrides on Organo-magnesium Bromides. Part I. The Action of Phthalic Anhydride on Magnesium α -Naphthyl Bromide." By SAMUEL SHROWDER PICKLES and CHARLES WILZMANN.

Although Grignard's reaction has been extensively used for the production of hydrocarbons, alcohols, and acids from ketones and esters, the effect of this reaction on anhydrides does not seem to have been studied. With the object of discovering another method for the preparation of certain quinones and their derivatives, the magnesium reaction was tried with magnesium α -naphthyl bromide and phthalic anhydride. The course of the reaction may be expressed as follows:—

1. Formation of additive compound:—

2. Action of water and dilute acid:—

3. Further action of water:—

the product of the reaction being a keto-acid, in this case, α -naphthyl-*o*-benzoic acid.

Such acids, on treatment with strong sulphuric acid, pass almost at once into quinones, the foregoing acid, for example, yielding naphthanthraquinone.

Subsequent experiments have shown that the above reaction is capable of general application. Thus, using phthalic anhydride and bromobenzene, the authors have obtained benzoyl-*o*-benzoic acid and anthraquinone, and with phthalic anhydride and β -bromonaphthalene they have obtained β -naphthyl-*o*-benzoic acid and naphthacene-quinone.

Experiments are now being carried out in the aliphatic series with succinic anhydride and various fatty bromides.

178. "The Combustion of Ethylene." By WILLIAM ARTHUR BONE and RICHARD VERNON WHEELER.

The combustion of ethylene appears to be essentially a process of hydroxylation, that is, oxygen initially enters the hydrocarbon and is distributed between the carbon and hydrogen, giving rise to hydroxylated molecules, which sooner or later, according to the rapidity of the process, undergo thermal decompositions into simpler products. The stages in the combustion are represented by the following scheme:—

The more salient features of the experiments may be summarised as follows:—

1. There is no preferential combustion of either carbon or hydrogen when ethylene interacts with a quantity of oxygen insufficient to burn it completely to steam and oxides of carbon. The separation of carbon or hydrogen, when it does occur, is to be entirely ascribed to secondary thermal decompositions.

2. Formaldehyde is the most prominent intermediate oxidation product, and at low temperatures its formation is probably preceded by that of a less oxygenated product.

3. The formation of aldehydes precedes that of steam and oxides of carbon.

4. The stage in the combustion process at which secondary decompositions set in is determined entirely by the temperature conditions. Below the ignition point, such changes do not come into play to any appreciable extent until the stage corresponding with the formation of formic acid is reached. The greater part of this substance then decomposes into carbon monoxide and steam, whilst the remainder is further oxidised to carbonic acid, which in turn breaks down into carbon dioxide and steam. Above the ignition point, the formaldehyde produced rapidly decomposes into carbon monoxide and hydrogen.

5. There is no separation of carbon or liberation of acetylene, even in the explosive combustion of ethylene, except when the oxygen present is insufficient to burn the hydrocarbon to formaldehyde. In such circumstances the excess of ethylene is thermally decomposed, yielding carbon, hydrogen, methane, and traces of

acetylene. Some evidence was obtained under suitable conditions of the transformation of the initial product, $\text{CH}_2\text{CH}:\text{OH}$, into the isomeric acetaldehyde, which is then independently oxidised to carbon monoxide, water, and formaldehyde, as proved in a previous paper.

The authors have not yet decided whether at low temperatures the oxygen is conveyed to the hydrocarbon directly or indirectly, but at high temperatures, as, for example, in the explosion wave, it is believed that there is a direct passage from

as the result of collisions between single molecules of ethylene and oxygen.

179. "The Decomposition of Methylcarbamide." By CHARLES EDWARD FAWCETT.

This investigation has been conducted on similar lines to that on carbamide (*Zeit. Physical. Chem.*, 1902, xli., 601), and it is found that the mechanism of the decomposition is precisely similar in the two cases, so that the theory put forward to explain the decomposition of carbamide is also applicable in the present instance.

The decomposition of methylcarbamide by acids is due to a transformation of the methylcarbamide into methylamine cyanate, which is subsequently decomposed by the acid. The initial transformation is a reaction of the first order, and the velocity coefficient at 99° is almost exactly one-half that of carbamide. In these experiments it is only the free methylcarbamide which represents the active concentration of substance decomposing at any instant. A direct hydrolysis is brought about only very slightly even by very concentrated alkali, and the reaction with pure water is very much slower than is the case with carbamide.

180. "Position Isomerism and Optical Activity: the Methyl and Ethyl Esters of Di-*o*-, *m*-, and *p*-Nitrobenzoyl-tartaric Acids." By PERCY FARADAY FRANKLAND and JOHN HARGRE.

The authors describe the preparation and properties of the six esters in question, which were obtained by the action of the three isomeric nitrobenzoyl chlorides on methyl and ethyl tartarates respectively. The rotation of each was determined in the fused state, and over a wide range of temperature, in some cases from 15° to 180° . All these compounds, like the corresponding dibenzoyl- and ditoluyll-tartrates, are strongly levorotatory. The *p*- and *m*-nitrobenzoyl groups were found to exercise a very great rotatory effect, the molecular rotations of the diethyldi-*p*- and di-*m*-nitrobenzoyltartrates and of the dimethyl di-*p*-nitrobenzoyltartrate being considerably in excess of those exhibited by the corresponding dibenzoyl- and ditoluyll-tartrates. The dimethyl di-*m*-nitrobenzoyltartrate, on the other hand, exhibited a molecular rotation, which, although considerably greater than that of dimethyl dibenzoyltartrate, was almost identical with that of dimethyl di-*m*-toluylltartrate.

The *o*-nitrobenzoyl group behaved in an altogether exceptional manner, its relative rotatory influence being entirely dependent on the temperature. Thus it has been previously shown by one of the authors (P. Frankland and Wharton, *Trans.*, 1896, lxi., 1591) that the rotatory effect of the *o*-toluyll group is inferior to that of the benzoyl group, and it would have been anticipated, therefore, that the *o*-nitrobenzoyl radicle should exert a still smaller effect; this was actually found to be the case above 130° , but with fall of temperature its rotatory effect so rapidly increases that at 15° the latter proved to be even greater than that of the *p*-nitrobenzoyl group. This abnormal behaviour of the *o*-nitrobenzoyl group, which was only fully studied in the case of the ethyl compound, was thus limited to the superheated state, the melting-point of diethyl di-*o*-nitrobenzoyltartrate being 143° . This melting-point, again, is exceptional in being considerably higher than

that of the meta- (95.8°) and that of the para- (124.5°) compounds respectively.

The rotation of all these compounds is very sensitive to temperature, diminishing in every case as the latter rises, much the largest temperature-coefficient being possessed by the ortho-compound.

181. "The Action of Nitrogen Sulphide on Organic Substances." (Part II.) By FRANCIS ERNEST FRANCIS and OLIVER CHARLES MINTY DAVIS.

The action of nitrogen sulphide on anisaldehyde gives rise to tri-*p*-methoxycyanidine and anisamidine sulphate, which are isolated by taking advantage of their solubilities in benzene and water respectively. An insoluble derivative of anisamidine, containing sulphur, is also produced which is very stable towards alkalis, but yields anisoylanisamidine on treatment with strong acids.

182. "Reduction Products of α, β -Dimethylanthracetonebenzil, and Condensation Products of Benzaldehydes with Ketones." By FRANCIS ROBERT JAPP and WILLIAM MAITLAND.

When α, β -dimethylanthracetonebenzil is boiled for a few minutes with fuming hydriodic acid, it is reduced to a cyclopentenone derivative (m. p. 122°):—

This compound is identical with that which Vorländer and Wilcke (*Ber.*, 1898, xxxi., 1877) obtained by the action of hydrogen chloride on dimethyldiphenyltetrahydro- γ -pyrone, but which they erroneously regard as dibenzylidenediethylketone. By further reduction with hydriodic acid, it yields the corresponding cyclopentanone derivative.

The authors have prepared various alkyl derivatives of tetrahydro- γ -pyrone by the usual method of condensing benzaldehyde with aliphatic ketones, and have studied their reactions, especially with the view of obtaining cyclopentenone derivatives.

183. "Interaction of Sodium Phenylglycidate with Phenylhydrazine." By FRANCIS ROBERT JAPP and WILLIAM MAITLAND.

When sodium phenylglycidate is heated with phenylhydrazine in alcoholic solution at 100° , 4-hydroxy-1:5-diphenyl-3-pyrazolidone (m. p. 173.5°) is obtained in the form of its sodium salt:—

By the action of heat or of dehydrating agents hydroxydiphenylpyrazolidone is converted into 1:5-diphenyl-3-pyrazolone,—

(m. p. 252°), previously obtained by Knorr (*Ber.*, 1887, xx., 1107) by distilling cinnamoylphenylhydrazine.

184. " α -Benzoyl-3-trimethacetylstyrene." By FRANCIS ROBERT JAPP and WILLIAM MAITLAND.

The authors have obtained α -benzoyl-3-trimethacetylstyrene,—

(m. p. 115°), by the action of potassium hydroxide on a mixture of benzil and methyl *tert*-butyl ketone. In its reactions, it closely resembles α, β -dibenzoylstyrene (Japp and

Klingemann, *Trans.*, 1890, lvii., 662, except that, on heating, it is converted into a mixture of two isomeric crotonolactones.—

(m. p. 150°) and—

185. "Olefinic Ketonic Compounds." By SIEGFRIED RUHEMANN.

Rabe (*Ber.*, 1902, xxxv., 3947) stated that the additive compound of aniline and ethyl benzylideneacetoacetate melted at 78° instead of at 105° (erroneously printed as 103°) as found by Ruhemann and Watson (*Trans.*, 1904, lxxxv., 1170). On re-examination, it was found that the melting-point could be raised to 106 – 107° , which closely agreed with that given by Francis (*Ber.*, 1903, xxxvi., 937) for the substance he obtained by combining benzylideneaniline with ethyl acetoacetate.

The author also examined the action of potassium cyanide on benzylideneacetylacetone and ethyl benzylideneacetoacetate respectively, and found that in the first case cyanobenzylacetylacetone, $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{CN}) \cdot \text{CH}(\text{CO} \cdot \text{CH}_3)_2$ (m. p. 127 – 128°), and, in the other, ethyl cyanobenzylacetoacetate, $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{CN}) \cdot \text{CH}(\text{CO} \cdot \text{CH}_3) \cdot \text{CO}_2 \cdot \text{C}_2\text{H}_5$, are produced. On hydrolysis with caustic potash, the former nitrile furnishes phenylacetylpropionic acid $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CH}_3$, whilst ethyl cyanobenzylacetoacetate yields a mixture of phenylacetylpropionic and phenylsuccinic acids. Under the influence of concentrated sulphuric acid, cyanobenzylacetylacetone is transformed into phenylacetylpropionic acid, $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}(\text{CO} \cdot \text{CH}_3)_2$ (m. p. 149 – 150°); ethyl cyanobenzylacetoacetate, on the other hand, furnishes the dihydropyrene derivative,—

The mode of formation and the properties of cinnamylideneacetylacetone, $\text{C}_6\text{H}_5 \cdot \text{CH} \cdot \text{CH} \cdot \text{CH} \cdot \text{C}(\text{CO} \cdot \text{CH}_3)_2$ (m. p. 103 – 104°), are also described. This di-olefinic ketone, on exposure to light, undergoes a change similar to that occurring in the case of cinnamylidenemalonate (Liebermann, *Ber.*, 1895, xxviii., 1440; Riiber, *Ber.*, 1902, xxxv., 2411), and yields a colourless substance (m. p. 158 – 159°) which has double the molecular weight of cinnamylideneacetylacetone. These two compounds are still under examination.

186. "Δ^o Oleic Acid." By HENRY RONDEL LE SUEUR.

In a former communication (*Trans.*, 1904, lxxxv., 827), the author stated that he was engaged in the preparation of an isomeride of oleic acid containing the double linking between the α- and β-carbon atoms, and, although the work is not complete, the appearance of a paper by G. Ponzio (*Gazzetta*, 1904, xxiv., [2], 77; *Chem. Centr.*, 1904, ii., 691) on the same subject necessitates the publication of the results so far obtained.

Δ^o-Oleic acid, $\text{C}_{15}\text{H}_{31} \cdot \text{CH} \cdot \text{CH} \cdot \text{CO}_2\text{H}$, obtained by the action of alcoholic potash on α-bromostearic acid, crystallises from light petroleum in long flat needles melting at 58 – 59° ; its ethyl ester melts at 25 – 26° . The acid, on oxidation with potassium permanganate, yields αβ-dihydroxystearic acid melting at 126° , which on further oxidation yields palmitic acid, thereby proving the position of the double linking.

187. "Action of Magnesium Alkyl Halides on Derivatives of Camphor." By MARTIN ONSLOW FORSTER.

The action of magnesium alkyl halides on derivatives of

camphor has been always normal, and several interesting changes have been observed.

The compound, $\text{C}_{12}\text{H}_{22}\text{O}_2$, from camphorquinone and magnesium methiodide is a volatile colourless compound, dissolving readily in organic media and very sparingly in water, from which it crystallises in minute transparent prisms and needles melting at 132° . A 2 per cent solution in absolute alcohol is optically inactive.

The compound, $\text{C}_{11}\text{H}_{19}\text{O}_2\text{N}$, from isonitrosocamphor and magnesium methiodide is soluble in acids and alkalis, forming colourless solutions; it separates from boiling water as a crystalline powder, and melts at 180° .

The compound, $\text{C}_{11}\text{H}_{19}\text{O}_3\text{N}$, from nitrocarnphor and magnesium methiodide is insoluble in sodium carbonate solution, but dissolves in aqueous sodium hydroxide; it crystallises from petroleum in lustrous leaflets melting at 83° .

The compound from hydroxymethylenecamphor and magnesium methiodide is a colourless fragrant oil which boils at $234^\circ/765$ m.m., has sp. gr. 0.9639, and $[\alpha]_D^{20}$ 170 – 8° . It is insoluble in aqueous sodium hydroxide, and gives no colouration with ethereal ferric chloride.

188. "Sulphonchloroalkylamines." By FREDERICK DANIEL CHATTAWAY.

In the course of an investigation of nitrogen halogen derivatives of the sulphonamides, a number of compounds yielded by various methyl, ethyl, and benzyl derivatives of the sulphonamides have been obtained. All the sulphonalkylamides are readily converted by a solution of hypochlorous acid into the corresponding chloroamides, $\text{RSO}_2 \cdot \text{NHR}' + \text{HOCl} = \text{RSO}_2 \cdot \text{NClR}' + \text{H}_2\text{O}$. Those containing methyl and ethyl groups are comparatively stable, whereas those in which benzyl occurs undergo spontaneous decomposition after a few hours; even when kept in dry air, chlorine and hydrogen chloride are liberated, while a pungent odour, resembling that of benzaldehyde, becomes apparent. When rapidly heated, they all decompose with evolution of gas, but without explosion. Like the sulphonchloroamides, they are very reactive, and promise to be of considerable value in the synthesis of secondary amines containing different alkyl groups.

The following compounds are typical examples of a long series of these substances which have been prepared:—Benzenesulphonchloromethylamide, $\text{C}_6\text{H}_5 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_3$, colourless, short rhombs, m. p. 81° ; benzenesulphonchloroethylamide, $\text{C}_6\text{H}_5 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{C}_2\text{H}_5$, colourless plates, m. p. 52° ; benzenesulphonchlorobenzylamide, $\text{C}_6\text{H}_5 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5$, colourless, slender prisms, m. p. 109° ; *p*-toluenesulphonchloromethylamide, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_3$, colourless prisms, m. p. 82° ; *m*-nitrobenzenesulphonchloromethylamide, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_3$, pale yellow four-sided plates, m. p. 136° ; α-naphthalenesulphonchloromethylamide, $\text{C}_{10}\text{H}_7 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_3$, colourless six-sided prisms, m. p. 78° ; α-naphthalenesulphonchlorobenzylamide, $\text{C}_{10}\text{H}_7 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5$, very pale yellow prisms, m. p. 94° ; β-naphthalenesulphonchloromethylamide, colourless prisms, m. p. 91° ; β-naphthalenesulphonchloropropylamide, $\text{C}_{10}\text{H}_7 \cdot \text{SO}_2 \cdot \text{NCl} \cdot \text{C}_3\text{H}_7$, colourless plates, m. p. 86° .

PHYSICAL SOCIETY.

Ordinary Meeting, November 25th, 1904.

Dr. R. T. GLAZEBROOK, F.R.S., President, in the Chair.

A PAPER ON "The Measurement of Small Differences of Phase" was read by Dr. W. E. SUMPNER.

Hitherto, in order to measure the differences of phase between alternating-current quantities, it has been necessary to use some method involving the simultaneous reading of three deflectional instruments, such as the wattmeter method, or the three-voltmeter method either in its original or in some modified form. These methods

cannot be successfully applied when the phase-differences to be determined are small. The author describes new voltmeter methods which may be used for the purpose, and gives the results of a number of measurements on alternating-current plant. Difficulties arising in the measurement of very small alternating-current voltages are overcome by rectifying the voltages so as to utilise sensitive direct-current instruments. The paper gives the results of some tests on two transformers of 3 kilowatt capacity intended to work between voltages of 100 and 2000, and with currents of 100 cycles per second. One transformer was used to step up the volts from V_1 to V_2 , the other to step down from V_2 to V_3 . It was found that the phase-difference between V_1 and V_3 for a non-inductive load increases regularly with the current. For an inductive load there is a sharply defined minimum at low power factor. The author suggested that points on one side of the minimum corresponded to a lag, and points on the other side to a lead of the current on the voltage in the primary circuit.

Dr. A. HAY congratulated the author, and said that the determination of power factors was a matter of importance. He had found that alternators tested with water resistances gave better results than when tested with lamps. The phase-differences between the volts and the amperes in the water resistances were generally greater than those indicated by Dr. Sumpner. He asked the author what current-density he used, and pointed out that the result would depend upon the current-density at the electrodes. A minimum phase-difference could be obtained by loading up the secondary of an ordinary transformer, and was due to an increase in the power factor up to a certain point and then a decrease. We were dealing with lag in both cases.

Mr. A. CAMPBELL said that some years ago (*Journ. Inst. Elec. Engineers*, April, 1901) he published a description of the method of measuring a phase-difference, close to 180° , between two independent voltages by the first method mentioned by Dr. Sumpner, viz., by shunting the larger by a high resistance, picking off from it a part as nearly as possible equal to the other, and measuring the difference resultant. A test on a small transformer gave a phase-difference of about $(180-0.15^\circ)$. Dr. Sumpner, however, has considerably improved the method; he ensures the sufficient equality of the components by adjusting until the resultant is a minimum—a simple and beautiful device. In his discussion of the three-voltmeter method, Dr. Sumpner assumes that three instruments are necessary. Mr. Campbell has found that in many cases a single instrument with a quick change-over switch is quite sufficient provided a number of readings are taken in rotation and averages obtained. With respect to Dr. Sumpner's method of measuring small alternating voltages by rectifying them, although it might give good results when the wave-form was known, he thought that in the very cases where such measurements were wanted the wave-form was not known. Small differences of "power" phase may be as much due to small differences in wave-form as to small displacements of similar waves: thus the "difference" resultant is probably nearly always of very uncertain wave-form.

Mr. T. H. BLAKESLEY expressed his interest in the paper, and said that many years ago he had made use of commutation in order to work with direct-current instruments. He had used a high-resistance galvanometer, and found that not only the self-induction but also the capacity of the coils had to be eliminated.

Mr. W. DUDELL supported Mr. Campbell in his contention that small differences of "power" phase might be due to small differences in wave-form. He had used water resistances in testing large alternators, but had never found any phase-difference between the voltage and the current. He had usually worked with high voltages, so that condenser effects due to polarisation (of the order of one volt) would have little effect.

Dr. C. V. DRYSDALE said he had given a good deal of attention to the measurement of small phase-differences,

and had found it advantageous to measure the sine of the phase-difference instead of the cosine. This could be accomplished by putting a condenser in series with the pressure circuit of a wattmeter so as to produce a phase displacement of nearly 90° . In these circumstances he had previously shown that with ordinary conditions the watts were equal to the wattmeter reading plus a constant multiplied by the sine of the angle of phase-difference. When, as was usually the case, $\sin \theta$ was nearly equal to unity it was only necessary to add a constant to the wattmeter reading.

Dr. W. E. SUMPNER, in reply to Prof. Hay, said he had worked with low current-densities and was unable to say what would happen if the current-density was increased. With regard to rectification he was aware of the effect of the shape of the wave. He had made experiments with currents of very different wave-forms, and in his opinion only about 20 per cent of the observed results could be due to any alteration in the form of the wave. His methods were suggested as a means of getting an approximate value of very small phase-differences, which could not be determined in other ways. The difficulties referred to by Mr. Blakesley were not encountered, as he had worked with a moving coil galvanometer of small capacity and self-induction. He was afraid that the observations of Dr. Drysdale raised questions which it would take too long to discuss at the present meeting.

A paper "On the Curvature-method of Teaching Geometrical Optics," by Dr. C. V. DRYSDALE, was postponed, at the author's request, in order that advance proofs might be in the hands of Fellows before the reading of the paper.

Dr. C. V. DRYSDALE then exhibited and described apparatus for the direct determination of the curvatures of small lenses, such as the objectives of microscopes. Parallel light from a distant source falls upon a plane unsilvered mirror inclined at an angle of 45° . Some of the light is reflected and brought to a focus by an ordinary convex lens. The surface to be tested is placed at this point, and the reflected rays proceed as if they had come from a point on the surface. They pass through the plate glass into a telescope focussed for parallel rays, and an observer sees an image of the distant source. If the surface is convex and is brought nearer to the lens, then, when it reaches such a position that its centre of curvature is at the focus of the rays emerging from the lens, the light will again retrace its former path and a distinct image of the source will be seen in the telescope. In order to obtain the two images the surface has therefore been moved through a distance equal to its radius of curvature. If the surface is concave it must be moved away from the lens. Dr. Drysdale showed how the method could be carried out by means of an auxiliary piece fitted to an ordinary microscope. He also described a method of testing the spherical and chromatic aberration of microscopic objectives. Light from a distant point is partially reflected by means of a piece of plate-glass down the axis of the microscope. In passing out of the objective it is brought to a focus upon a mirror and retraces its path along the axis of the instrument until it reaches the plate-glass. This it passes through, and by means of a telescope an observer can view the distant source. The light having passed twice through the lens to be investigated, the effects of chromatic and spherical aberration are doubled and at the same time the effect of coma is eliminated.

Prof. S. P. THOMPSON then gave an Exhibition of Specimens of Crystals showing the phenomenon of Luminous Rings.

He said it was well known that when a source of light was viewed through certain samples of calc-spar the field of vision contained two luminous rings each of which passed through the image of the luminous point. The subject had been investigated by Dr. Johnstone Stoney, who had attributed the phenomenon to a minute tubular structure in the crystal. There were, however, certain crystals which when cut in the ordinary way across the

axis and used to view a distant source of light, exhibited a single luminous ring passing through the image of the source. Looking down the axis of the crystals no ring is visible, but on tilting it a ring can be seen in the direction of the tilt which grows in diameter as the tilt is increased. So far as he knew no explanation of these phenomena had been offered. At the meeting, a piece of calc-spar showing the two rings and pieces of beryl and tourmaline showing the single ring were exhibited.

A paper "On a Rapid Method of Approximate Harmonic Analysis," by Prof. S. P. THOMPSON, was postponed.

Several of the Laboratories of the College were open to the inspection of Fellows, and apparatus was exhibited by Prof. Dalby, Mr. Darling, Dr. Drysdale, and Prof. Thompson.

ROYAL SOCIETY OF NEW SOUTH WALES.

Wednesday, October 5th, 1904.

C. O. BURGE, M.Inst.C.E., President, in the Chair.

THE following papers were read:—

"Preliminary Observations on Radio-activity and the Occurrence of Radium in Australian Minerals," by D. MAWSON, B.E., Junior Demonstrator, and T. H. LABY, Acting-Demonstrator of Chemistry in the University of Sydney. (Communicated by Prof. T. W. E. DAVID, B.A., F.R.S.)

A brief summary of observations on the radio-activity of minerals and occurrence of radium is given, showing that comparatively intense activity is only found associated in minerals with thorium and uranium. Bottwood and Strutt have independently shown that usually radium and uranium content are proportional. In these experiments the ionisation produced in an air gap was determined by measuring the saturation current across it, first with the mineral and then with black uranium oxide. Thus the activity compared to black uranium oxide was obtained. The presence of radium was looked for by Strutt's application of Rutherford and Soddy's discovery that radium gives off a radio-active gas, the emanation, which decays in activity to half its initial value in four days. A torbernite and euxenite were found highly active, but the specimens were too small to examine for radium. A Western Australian gadolinite, found by Professor Norman Collie to contain one bubble of helium in 10 grms., was expected to contain radium, but none could be detected. Twelve monazites were found radio-active; one, with double the average activity of the others, from Pilbarra, Western Australia, gave on heating the radium emanation; five monazite and zircon sands were also active. No relation between thorium contents and activity was found, which points to the presence of uranium.

Remarks were made by Prof. David, Prof. Pollock, Mr. G. H. Knibbs, Mr. F. B. Guthrie, Mr. W. M. Hamlet, the authors, and the President.

"The Flood Deposits of the Hunter and Hawkesbury Rivers," by Acting-Professor F. B. GUTHRIE, F.I.C., F.C.S., and Professor T. W. EDGEWORTH DAVID, B.A., F.R.S., F.G.S.

During the floods last July in the Hunter and Hawkesbury rivers, samples of the flood water as well as of the flood silt were collected, at the instance of the authors, by Mr. A. J. Prentice, B.A., of West Maitland, and Mr. W. W. H. Potts, the Principal of the Hawkesbury Agricultural College. Determinations made at the laboratory of the Department of Agriculture show the following to be the chemical composition of the silts:—

Silt from Hunter River Flood Water, West Maitland.

Insoluble in hydrochloric acid	Per cent.
Soluble in hydrochloric acid—	= 79.25
Oxide of iron and alumina (Fe_2O_3 and Al_2O_3)	= 10.02
Lime (CaO)	= 1.55
Potash (K_2O)	= 0.09
Phosphoric acid (P_2O_5)	= 0.18
Volatile matter	= 9.61
Nitrogen	= 0.084

Weight per acre, one foot in depth = 3,403,125 pounds.

Silt from Hawkesbury River Flood Water.

Insoluble in hydrochloric acid	= 89.96
Soluble in hydrochloric acid—	
Oxide of iron and alumina (Fe_2O_3 and Al_2O_3)	= 4.77
Lime (CaO)	= 0.49
Potash (K_2O)	= 0.12
Phosphoric acid (P_2O_5)	= 0.08
Volatile matter	= 4.68
Nitrogen	= 0.105

Weight per acre, one foot in depth = 3,307,332 pounds.

Mr. Prentice estimates the average depth of the last flood deposit of the Hunter to be about two inches. This would supply the land with a top dressing of fertilising constituents to the following amount per acre:—

	Pounds.
Lime	8791
Potash	510
Phosphoric acid	1020
Nitrogen	476

The data for estimating the thickness of silt deposited by the Hawkesbury river are less complete than those for the Hunter. On the assumption that the thickness was only one-twentieth of that deposited by the Hunter river, the silt of the Hawkesbury flood would weigh 27,561 pounds per acre, and would supply per acre:—

	Pounds.
Lime	135
Potash	33
Phosphoric acid	22
Nitrogen	29

A discussion was commenced by Mr. J. H. Maiden, Dr. R. Greig Smith, and Prof. F. B. Guthrie, but on the motion of Mr. C. A. Süssmilch it was postponed to the next meeting.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 18, October 31, 1904.

The Atomic Weight of Aluminium.—M. KOHN-ABREST.—Two methods were used for finding the atomic weight:—(1) The metal was treated with hydrochloric acid, and the hydrogen produced was led over red-hot copper oxide and weighed as water. The mean of several experiments gave 27.05 ($\text{H}=1$, $\text{O}=15.88$) as the atomic weight. (2) Aluminium was converted into alumina; the atomic weight by this method was 27.09. The specimens of aluminium used for the above experiments were carefully analysed.

Action of the Halogen Derivatives of the Tri- and Penta-valent Metalloids upon Alkyl Halogen Compounds.—V. AUGER.—Already noticed.

Tetrahydride and Decahydride of Naphthalene.—Henri Leroux.—An account is given of the properties of the 8-tetrahydride and of the substances produced by acting upon it with chlorine and bromine. The decahydride was obtained by hydrogenising the tetrahydride. It is a colourless liquid with an agreeable smell; it boils at at 187—188°, and is decomposed when heated with lime to a red heat, naphthalene being produced. It acts energetically with chlorine, and monochloro- ($C_{10}H_{17}Cl$) and dichloro- ($C_{10}H_{16}Cl_2$) derivatives are obtained.

The Oxidation of Methyl and Ethyl Alcohols at the Boiling-points of these Substances.—René Duchemin and Jacques Dourlen.—The object of these researches was to find why the burners of alcohol lamps deteriorate so rapidly. The authors have proved—(1) That certain alcohols, sold as neutral, and which do not redden litmus-paper, contain acid in sufficient quantity to be estimated by soda, using phenolphthalein as indicator. (2) Both methyl and ethyl alcohols, under certain conditions, at their boiling-points give rise to acid, the amount of which increases with the duration of the distillation.

The Action of the Chlorides of Phosphorus upon Aromatic Organo-magnesium Derivatives.—R. Sauvage.—The author has studied the action of the oxychloride of phosphorus upon phenyl-magnesium bromide, benzyl-magnesium chloride, and α -naphthyl-magnesium bromide. Compounds having the formulae $R_3\equiv P=O$ and $R_2=P\equiv O$ seem to be produced. The latter, when decomposed by water, yields $R_2=P\equiv O$.

The Tetraoxycyclohexane Rosanilines.—Jules Schmidlen.—A colourless oxalate of malachite green has been recently described by Lambrecht and Weil. This salt, when heated to 70°, loses four molecules of water and is transformed into the coloured oxalate of malachite green. The composition and properties of the colourless oxalate show that it is a tetraoxycyclohexane rosaniline. Its behaviour on heating is therefore a new confirmation of the theory that a benzene nucleus of carbinol passes through a hexahydrobenzene stage before being finally transformed into a quinone nucleus.

The Density of Nitrogen Monoxide and the Atomic Weight of Nitrogen.—Already noticed.

MISCELLANEOUS.

Gunning Victoria Jubilee Prize.—The Council of the Royal Society of Edinburgh at its recent meeting decided to award Professor Sir James Dewar, F.R.S., the Gunning Victoria Jubilee Prize for 1900—1904, for his researches on the liquefaction of gases, extending over the last quarter of a century, and on the chemical and physical properties of substances at low temperatures.

Institute of Chemistry.—*Examination in Biological Chemistry.*—The following Candidates passed:—*Fellow:* Robert Macfarlane Clark, B.Sc. (Glasgow). *Associates:* Francis William Frederick Arnaud, Henry Wulff Kinnersley, Louis John Ezekiel Riley. *Candidates for the Associateship:* Walter Augustus Handcock, Francis Richard Henley, M.A. (Oxon.).

The Formation of Formic Aldehyde in the Combustion of Tobacco.—M. A. Trillat.—Experiments show that aldehydes (chiefly formic) are produced by the combustion of tobacco; they do not exist in the free state, but immediately they are formed they combine with the nitrogen bases present.—*Comptes Rendus*, cxxxix., No. 19.

MEETINGS FOR THE WEEK.

- MONDAY, 5th.—Society of Arts, 8. (Cantor Lectures). "Musica Wind Instruments," by David James Bleikley.
Society of Chemical Industry, 8. "Raschig's Theory of the Lead Chamber Process," and "Theory of the Action of Metals on Nitric Acid," by Dr. E. Divers.
"A Rapid and Accurate Method for the Estimation of Phosphorus in Iron Ores," by Llewellyn J. Davies.
"Fluoroscope for Comparing Substances under the Influence of Radium Rays," by C. S. Stanford Webster.
Royal Institution, 5. General Monthly Meeting.
WEDNESDAY, 7th.—Society of Arts, 8. "The International Exhibition at St. Louis, U.S.A.," by Walter F. Reid, F.I.C. &c.
THURSDAY, 8th.—Society of Arts, 4.30. "Burma," by Sir Frederic W. R. Fryer, K.C.S.I., late Lieut.-Governor of Burma.
FRIDAY, 9th.—Physicist, 8. "Rapid Method of Approximate Harmonic Analysis," by Prof. S. P. Thompson. "High-frequency Alternator," by W. Duddell. Exhibition of Experiments to show the retardation of the signalling current on 3500 miles of the Pacific Cable between Vancouver and Fanning Island. Exhibit of Ayrton-Mather Galvanometers, Universal Shunts and Electrostatic Instruments, a New Type of Wattmeter, a New Form of Inductionless Resistance, and of other Instruments.

GOVERNMENT GRANT to defray the expenses of Scientific Investigations. Applications for the year 1905 must be received at the Offices of the Royal Society not later than JANUARY 31 next, and must be made upon printed forms to be obtained from the Clerk to the Government Grant Committee, Royal Society, Burlington House, London, W.

READ HOLLIDAY & SONS, Ltd.,

VOL. XC., No. 2350.

THE ABSTRACTING OF CURRENT CHEMICAL LITERATURE.

By HUGH MARSHALL, D.Sc., F.R.S.

JUST as the rapid growth of the science of chemistry long since made it impossible for individual workers to take particular note of the literature of more than their own special departments, and rendered advisable the publication of short abstracts of original papers so as to enable workers to take a rapid review of the general literature, so now the continued expansion is beginning to make the provision of even highly condensed reports, in a thorough and efficient manner, a matter of considerable difficulty, or, at least, of considerable expense. The Berlin Chemical Society, which now publishes the well-known *Central-Blatt*, devoted entirely to abstracts of current chemical literature, has just issued a notice to the subscribers calling attention to the great increase of matter in the last few years, and intimating an increase of the price from twenty-eight to thirty-eight Marks per annum.

In view of the circumstances, it appears desirable that in the immediate future this whole question should be most carefully considered by the various bodies responsible for the publication of abstracts, and an endeavour made to arrive at some improved plan of dealing with it which would be efficient and economical. The following suggestions are made in the hope that they may lead to something being done in this direction.

The fact that the *indexing* of scientific literature generally is now being carried out on an international basis, immediately suggests the possibility of a somewhat similar method of international co-operation for abstracting chemical literature. At present, owing to the entire absence of co-operation, there is, even in one and the same language, a great amount of overlapping, and the same work is done repeatedly by different abstractors, and presumably has to be paid for in each case. For example, we have, in English, abstracts appearing in the *Journal of the Chemical Society*, the *Journal of the Society of Chemical Industry*, the *Journal of the American Chemical Society*, the *CHEMICAL NEWS*, and a number of others, some of them more or less specialised in character. An original paper may be, and often is, separately abstracted for every one, or nearly every one, of these periodicals; the same is the case with publications in other languages. There is, however, no special reason why a paper should be abstracted by more than one abstractor, provided the latter is expert at the work. Evidently, therefore (if we look at the matter in a sufficiently comprehensive way), there is room for a considerable saving of labour, and consequently of expense, and this might be effected in some such way as the following:—

For the sake of argument we may assume that the publication of abstracts in three languages (English, French, German) is desirable and sufficient; the actual number is immaterial. Let the leading chemical societies represented in these languages appoint an International Commission whose duty it would be to prepare a complete *résumé* of the current chemical literature of all countries, and either to publish the same themselves in the three languages, or, preferably, to arrange for its publication by separate national organisations. The Commission would appoint a large number of abstractors, each of whom would deal only with papers appearing in his own language, and relating to some department in which he was sufficiently versed, and it would also maintain a staff of skilled translators. Possibly the work of abstraction might be simplified

by authors themselves supplying abstracts of their papers, it being understood that, as regards length, such abstracts should not exceed a given percentage of the original paper. As soon as the abstracts were ready they would be forwarded to the central office of the Commission, where they would be classified and provided with reference data (year of publication of abstract, class, and running number in that class). The abstracts would then be translated as literally as might be into the three languages (or two of them if originally in one of the three), and thereafter the appropriate copies would be transmitted to the respective publishers in England, France, and Germany.

The expenses of the International Commission (*i.e.*, the cost of *preparing* the abstracts) would be shared by the various organisations responsible for its appointment, but each of the national publication committees would be itself responsible for the publication of its own edition, just as the Berlin Chemical Society is at present responsible for its own *Central-Blatt*. The abstracts would be issued separately, like the *Central-Blatt*, not conjointly with the publication of original papers, like the Abstracts of the Chemical Society.

In addition to issuing a complete edition of the "Chemical Abstracts," each nationality might also have partial editions, confined to the various classes, or to groups of classes—Physical, Inorganic, Organic, Analytical, Technological, Patents, &c., for the convenience of readers whose interests in the science are limited to certain branches only. This could be quite easily arranged by allotting the space devoted to any one section, in the general edition, always in multiples of sixteen pages, and paging each section separately; in some of the issues certain of the smaller sections would not be represented at all. At the end of the year, subscribers to the complete edition would have it properly collated in sections for binding. One general index would suffice and would be supplied with the partial editions as well as with the complete one. The issuing of partial editions would render it superfluous for the more specialised journals, &c., to continue the publication of separate extracts; they could either arrange for their subscription to include the appropriate partial edition issued as above, or leave the matter entirely in the hands of their subscribers themselves.

In addition to the all-round economy, and increased efficiency, which ought to result from concerted action on some such basis as that sketched above, there would be very considerable advantages of another kind. For example, anyone who desired to supply himself directly with a considerable proportion of the current literature would not find a large part of his library stored, as at present, with repeated abstracts of the same papers. Another great advantage would be the simplification of "References," which would result. Thus, suppose an author, of a date subsequent to the introduction of the system, wished to mention the work of some other author; he would require to give only one reference, not to the paper itself (unless he specially desired to give this as well), but to the international abstract, in some such way as the following:—C. A. 1910, IV., 123. This would mean: Chemical Abstracts, Volume published in 1910, Class IV. (say, General Organic Chemistry), Abstract No. 123 (not page 123). Any English, French, or German reader could then refer to his own edition and turn up the appropriate abstract without the least difficulty. There, in addition to the abstract itself, he would get any particulars as to the place, date, &c., of the original paper not given in the first reference.

As already indicated, these suggestions are put forward tentatively, and are not to be looked upon as embodying a complete scheme. Should the proposal meet with sufficient approval to lead to its being put into practice, very many points will require careful consideration and elaboration in order to ensure success.

A step in the direction of an international scheme has already been taken, but only for physico-chemical papers, and not on the general lines here recommended. The

actual initiation of that scheme shows, however, that the difficulties in the way of the other ought not to be insuperable.

Chemistry Department,
University of Edinburgh

SOME PHYSICAL CHARACTERS OF THE SODIUM BORATES, WITH A NEW AND RAPID METHOD FOR THE DETERMINATION OF MELTING-POINTS.*

By CHARLES HUTCHENS BURGESS AND ALFRED HOLLIMAN

SOME time ago we published a note containing some new observations on the solubility of metallic oxides in fused boric anhydride (*Journ. Chem. Soc. Proc.*, 1903, p. 221). Since its publication we have been further studying some of the points therein mentioned, but have been in part anticipated by W. Guertel (*Zeit. Anorg. Chem.*, vol. xl., [2], pp. 225 and 268; vol. xl., [3], p. 337), who has examined many of the phenomena we remarked, in a more complete manner. As, however, our experiments do not cover exactly the same ground as his, we have arranged in the following paper the results relating to the sodium borates, which we believe are completely new, and, at the same time, present many interesting features towards the study of these complex bodies.

When a quantity of ordinary pure borax glass is heated for some hours at a temperature which gives it about the consistency of a thick syrup, it gradually changes to a mass of colourless crystals. The crystallisation begins at two or three points on the surface of the mass, generally around a particle of dirt, or minute fragment of imperfectly fused borax, and spreads in more or less spherulitic growths throughout the glassy portion. As the crystals grow, there appears to be a contraction of volume, since the glass around them appears as raised hummocks, and a subsequent investigation of the specific gravities of the crystals and glass showed that this was really the case.

The crystals do not seem to grow at a uniform rate. They start rapidly, but as development continues, they take longer and longer to form, so that many hours are occupied in changing from pure glass to a holocrystalline aggregate.

We have not been able to isolate any individual crystals, and so study their characters, but the whole crystalline mass appears to be composed of dense matted clusters of very minute needles, which are doubly refracting, and have a pearly lustre. They are about as soluble in water as ordinary borax glass, are not hygroscopic, and melt at a higher temperature than the glass, into which they are reconverted on melting, and then cooling quickly.

We find, however, that it is not borax glass alone which exhibits this phenomenon of crystallisation on re-heating, but that the glasses obtained by fusing mixtures of boric anhydride and sodium carbonate, in which the ratio of the boric anhydride to the sodium carbonate is not 2 : 1, also exhibit it in varying degree.

Thus all mixtures in which the ratio varies from 6 : 1 to 8 : 5, give a glass when fused, and are all capable of being changed completely into crystals on re-heating, exactly like borax. Mixtures in which the boric anhydride is present in greater proportion than 6 : 1, only change with difficulty on prolonged heating, and when they do, the crystals are always found to be mixed with more or less truly glassy material, till, when the ratio 40 : 1 is reached, it seems impossible to obtain crystals at all. So far as we can ascertain, a mixture of this composition is always a true glass in any circumstances.

Mixtures, on the other hand, in which the ratio of boric anhydride is less than 8 : 5 when fused, and allowed to cool, yield nearly opaque, white substances, which seem to be

micro-crystalline. Nevertheless, these mixtures, if heated to a high temperature, and then suddenly chilled by being poured into mercury, also yield glasses.

The glasses obtained by this sudden chilling seem to be very unstable, as on gently heating by means of a Bunsen flame, they change completely, and almost instantaneously, into crystals.

There seems then to be a gradual alteration in the rapidity and completeness with which this change occurs, and as it seemed probable that the crystallisation of some borate rich in sodium was the cause of it, we proceeded to determine what was the composition of the borate richest in sodium which could be obtained by fusing boric anhydride with sodium carbonate.

When boric anhydride is fused with sodium carbonate, carbon dioxide is evolved, and the product may be regarded as boric anhydride combined with sodium oxide (Na_2O). Thus, by heating boric anhydride with a large excess of sodium carbonate, and determining the amount of carbonate decomposed, the greatest proportion in which boric anhydride combines with sodium oxide can be ascertained, and ought to give the composition of the richest sodium borate obtainable by fusion.

We have performed this experiment several times, and have obtained the following results:—

- i. One part of B_2O_3 combines with 1.29 parts Na_2O .
- ii. One " " " 1.34 "
- iii. One " " " 1.32 "

These results are probably a little too low, as the sodium carbonate loses some carbon dioxide merely on heating alone, but this amount is negligible, and does not in any way affect the conclusion that the product obtained in this way is not sodium metaborate (NaBO_2), in which the ratio of boric anhydride to sodium oxide is 1 : 1, and that sodium orthoborate ($\text{Na}_2\text{B}_2\text{O}_7$), in which the ratio is 1 : 3, cannot in any case be formed by fusion of boric anhydride and sodium carbonate.

The object of the research became thus threefold:—

a. To determine what compounds are present in crystals obtained with various mixtures of boric anhydride and sodium carbonate.

b. What is the nature of the glass.

c. What is the nature of the change from glass to crystals.

The most obvious method seemed to be to determine the melting points of crystals and glasses of varying composition, to see if compounds existed, and to compare and correlate the melting point curves obtained. To do this it was necessary to employ some new melting-point method, as none is known by which the melting-point of glasses can be determined at all accurately.

We devised an apparatus which is somewhat similar to the "meldometer" described by Joly (*Roy. Irish Acad.*, 1889), and we found it to be both rapid and peculiarly suitable in the case of plastic substances, which have hitherto been supposed to possess no definite melting-point.* Our apparatus is represented in Fig. 1.

A uniform piece of platinum-wire, A A, about 4 cm. long, was welded to two stouter pieces of the same metal, B B. These were sealed into two thin glass tubes, and were welded to two thick copper wires, C C, which conveyed the current. The whole was fixed by two rubber stoppers in a glass tube, with an opening at D.

A small bead of the material whose melting-point was desired, was made on one end of a very thin platinum-wire, to which a weight of about a gramme was attached.

A current of 4–6 amperes was passed through the wire A A so as to raise its temperature considerably above that at which the bead melted. The bead was then inserted through the opening D, when on touching the wire it became fused. The current was switched off, and the bead, on solidifying, remained attached to the edge of the wire A A. Air currents were prevented by closing the opening D with a test-tube.

* We use the words "melting-point" to denote the sudden decrease in viscosity which occurs at a very well defined temperature in glasses.

FIG. 1.

FIG. 2.

A slowly increasing current was then passed through the wire till the portion of the bead in contact with it melted, when the weight and bead fell into the test-tube. The moment this occurred, the voltage between the ends of the wire and the ampères passing through it were carefully noted. From the values obtained the resistance was calculated, and thence the temperature.

The weight hanging from the bead had no decided effect on the melting-point. We found that with weights varying from 0.2-5 grms., the bead dropped off at practically identical temperatures. This temperature at which beads of various compounds drop off the wire is extremely well defined, even in the case of substances which become plastic on heating, like glass, so that provided no chemical change occurs during the heating, the method proved rapid and elegant. A certain amount of heat is conducted away by the ends of the thick platinum-wires BB to which they the thinner one AA is welded, and also by the bead itself. It therefore became necessary to calibrate the wire by means of pure salts of known melting-points.

We found this was a matter of some difficulty, as very many of the most ordinary salts were found to decompose to some extent on heating. Sodium chloride, sodium carbonate, potassium iodide, calcium chloride, and strontium chloride all underwent change. Of these salts sodium chloride was very little attacked, but after only a few minutes' fusion we found it had absorbed quite an appreciable amount of oxygen, being converted into the peroxide. Potassium iodide changed in part to iodate, sodium carbonate to the peroxide, and calcium and strontium chlorides to the oxides.

These changes completely prevented any accurate melting-point determinations, so after repeated trials we adopted potassium nitrate, lithium chloride, and potassium chloride as standards. It is true that potassium nitrate decomposes on heating, but as the nitrite (to which it changes) has almost the same melting-point, the small amount of change was found to be immaterial. The chlorides we employed seemed to be, on the whole, very stable.

The melting-points given in Carnelley's tables for these

three standard substances were assumed as correct; they were used in fixing three points on the temperature-resistance curve.

Thus, any temperature between the melting-points of potassium nitrate and potassium chloride could be obtained by interpolation from the measured resistance, and those above the melting-point of potassium chloride by extrapolation. The results did not seem to contain an error larger than 1 per cent, so that we considered the method was satisfactory enough. The melting-point curves for the glasses and crystals are represented on Fig. 2. The curve for the glasses presents some features which are difficult to explain, since, so far as we are aware, no such curve has before been described.

The addition of sodium oxide to boric anhydride raises the melting-point continuously till a mixture of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ is reached. There seems to be no depression of the melting-point at all, thereby differing from the case of ordinary solution, and indicating the probability that there is no solid phase.

The curve then remains fairly level till a composition $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$ is reached, when it falls irregularly to $\frac{1}{3}\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.

The last point we could obtain on this curve was with composition $\text{Na}_2\text{O} \cdot \text{B}_2\text{O}_3$, where the melting-point practically coincided with the temperature of change from the glassy to the crystalline state of this mixture. Indeed, it is a little above it, but it was possible by fairly rapid heating to melt the bead before the change had occurred.

At present we are unable to state exactly what the meaning of this melting-point curve for the glasses may be. Glasses have hitherto been supposed to possess no sharp melting-point, but this did not seem to be the case, as our results for each different temperature were remarkably close and well defined.

The melting-point curve for the crystals is more easily explainable than that of the glass.

We were unable to obtain any point on it between pure boric anhydride and a mixture of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$. This was because the crystallisation of the small mass of substance in the beads we employed for the melting-point determinations took an extremely long time, and also because the devitrification was never complete except in the neighbourhood of the mixture $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.

From a mixture of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ the melting-point falls nearly uniformly till $5\text{Na}_2\text{O} \cdot 8\text{B}_2\text{O}_3$ is reached, at which point it begins to rise rapidly. The mixture $5\text{NaO} \cdot 8\text{B}_2\text{O}_3$ would then appear to be a marked eutectic-point.

The summit of the curve is reached with composition $5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, when it falls again to a mixture which may be considered to have the composition $5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 4\text{Na}_2\text{CO}_3$, and which represents the eutectic-point between $5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ and Na_2CO_3 .

The further addition of sodium carbonate causes a gentle, almost uniform rise in the melting-points.

As the summit occurs with composition $5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, and as this very nearly agrees with the analysis of the borate richest in sodium, which can be obtained on fusion of boric anhydride and sodium carbonate, this would seem to indicate a compound.

The results of these melting-point determinations of the crystalline mixtures indicates that borax ($\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$) is not a definite compound in this state, but is almost a eutectic mixture of the borate with composition $5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ and one of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, for the existence of which we have other evidence.

This melting-point curve for the crystalline forms of these various mixtures cannot be regarded as truly representing either the *solidus* or *liquidus*. It seems probable that in this case they are situated close to each other, and that our melting-points really represent temperatures close to the liquidus. The fact that a mass of crystals would apparently melt almost completely at an almost constant temperature certainly indicates that there cannot be any

very great difference between the liquidus and solidus, and, as in the cases studied by Heycock and Neville, that the actually determined melting-points lie probably very near to the liquidus.

The following table gives the melting-points for the various glasses and crystals:—

Composition of mixture.	Melting-point	
	Glass.	Crystals.
B_2O_3	468°	—
$\text{Na}_2\text{O} \cdot 40\text{B}_2\text{O}_3$	470	—
$\text{Na}_2\text{O} \cdot 16\text{B}_2\text{O}_3$	528	—
$\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$	628	858°
$\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$	628	791
$9\text{Na}_2\text{O} \cdot 16\text{B}_2\text{O}_3$	613	—
$5\text{Na}_2\text{O} \cdot 8\text{B}_2\text{O}_3$	620	777
$3\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$	610	815
$\text{Na}_2\text{O} \cdot \text{B}_2\text{O}_3$	613	930
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$	—	960
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + \text{Na}_2\text{CO}_3$	—	917
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 3\text{Na}_2\text{CO}_3$	—	783
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 4\text{Na}_2\text{CO}_3$	—	654
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 5\text{Na}_2\text{CO}_3$	—	664
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 6\text{Na}_2\text{CO}_3$	—	692
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 7\text{Na}_2\text{CO}_3$	—	685
$5\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3 + 27\text{Na}_2\text{CO}_3$	—	722

A CHEAP KIPP'S APPARATUS.

By F. SOUTHERDEN, B.Sc., F.I.C.

IN many elementary experiments where a controllable stream of gas is required some inexpensive form of Kipp's apparatus becomes necessary. The writer has found the

contrivance here figured to be satisfactory. It may be fitted up in a few minutes, and is convenient to handle. Only a brief explanation need be given. An ordinary

"lime-tower" is the main feature, and down the centre of this passes a piece of wide-bore tubing, which fits loosely the constriction in the tower. This very effectually prevents solid entering the lower bulb, the zinc, marble, or iron sulphide being filled in after the tube is in position, whilst its open end is plugged with a stick or glass rod. The neck of the funnel is drawn out slightly, and a piece of glass tube attached so as to reach the bottom of the tower. To replenish the acid when exhausted it is blown up into the funnel, and emptied out. The piece of glass rod shown with the rubber cap serves as a stopper to the funnel when required, and to the outer tube when putting in fresh zinc; at other times it rests in the funnel.

Of course a tap-funnel and glass stopcock to the exit-tube makes a more elegant but needlessly expensive form of the apparatus. If used for sulphuretted hydrogen a clock-glass may be placed over the mouth of the funnel.

AN YTTRIC EARTH NEAR TO GADOLINIUM.

By G. URBAIN

IN 1895, M. Lecoq de Boisbaudran (*Comptes Rendus*, cxxi.) observed in certain dysprosiferous terbias a feeble absorption band, $\lambda = 488$, which he considered to be characteristic of an unknown element. He denoted this unknown substance by Z δ . Demarcay made similar observations (*Comptes Rendus*, cxxxi.; *CHEMICAL NEWS*, lxxvii., 97).

For several years I have been working upon the yttric earths, attempting to separate the different terms of the series, and to reduce the intermediate fractions to a minimum. The first portions of the fractionation consist of pale rose europium oxide and white gadolinium oxide; these are followed by coloured earths, the fractions gradually darkening in colour. The darkest earths show the absorption spectrum of dysprosium to a marked degree. In the intermediate fractions, between gadolinium and dysprosium, I have obtained by three different methods coloured earths whose absorption spectra consist of the single band of Z δ ($\lambda = 488$).

METHOD I. Fractionation of Double Nitrates of the Earths and Nickel.—The object of this fractionation was to reduce to a minimum the intermediate fractions between gadolinium and the following earths. I will describe it in detail in a future paper. The heads gave white gadolinium oxide; the tails gave very dark oxides, whose olive coloured solutions gave a strongly marked spectrum of dysprosium (consisting of three bands in the blue and violet which resemble those of praseodymium in their breadth and general appearance) a feeble spectrum of holmium, and a diffuse and almost imperceptible band of Z δ .

The intermediate fractions consist of less highly coloured oxides, whose almost colourless solutions give the single absorption band of Z δ ($\lambda = 488$).

METHOD II. Fractionation of the Simple Nitrates in the presence of Bismuth Nitrate.—Of the simple nitrates of the rare earths containing 5 molecules of water, the nitrate of gadolinium is the least soluble (Demarcay, *Comptes Rendus*, cxxx.). I have found that the solubility of the isomorphous nitrate of bismuth is intermediate between those of the nitrates of gadolinium and samarium. On fractionation, therefore, bismuth nitrate should collect at two points of the series on either side of gadolinium, granted the minimum of solubility in case of the nitrate of the latter. I thus hoped to effect a new separation in the series, the method being similar to that already employed by M. Lacombe and myself in the separation of samarium and europium (*Comptes Rendus*, cxxvii. and cxxviii.).

400 series of crystallisations of twenty fractions, or about 8000 crystallisations, were necessary before a positive result was obtained.

The fractions between gadolinium and dysprosium, which I expected to be of pure bismuth nitrate, contained a small quantity of a dark earth. The absorption spectrum of this earth consists only of the band of Z δ . Therefore the nitrate of Z δ has the same solubility as the nitrate of bismuth.

METHOD III. Fractionation of the Ethyl Sulphates.—M. Lacombe and myself have gone much further in the fractionation of the ethyl sulphates of the earths of this group than we were able to do in 1898 (*Ann. de Chim. et de Phys.*, 1900, xix.), and in every case the absorption spectrum of the earths isolated from the fractions between gadolinium and dysprosium consisted only of the band of Z δ .

By these different methods I have been able to obtain nearly 100 grms. of these earths, which I have put together, and am fractionating at the present time.

In no case have I been able to obtain the results announced by R. Marc (*Ber.*, 1902, xxxv.). The band $\lambda = 464$ which he observed could not belong to the earths of this group, since their solutions when they contain dysprosium have a greenish and not a pink tint.

M. Lecoq de Boisbaudran only observed the band $\lambda = 488$ (Z δ) in earths having other absorption spectra at the same time; the existence of an element characterised by this feeble band could only be hypothetical. My results, however, show clearly the presence of a new element, which is quite distinct from dysprosium.

I have prepared a fair quantity of this new earth, and hope to determine whether it consists of one or more than one element.

It is indeed possible that the earths which I have obtained contain, besides the element characterised by the band $\lambda = 488$, another element without an absorption spectrum. The oxides are all brown, and are mixed with peroxides; but so far it is impossible to decide whether these properties belong to elements with absorption spectrum Z δ , and to dysprosium, or to a substance without an absorption spectrum which occurs with them, and to which should be given the name of terbium.

I have kept, provisionally, the notation Z δ for this element which possesses one single absorption band $\lambda = 488$.—*Comptes Rendus*, cxxxix., No. 19.

HYDRONITRIC ACID AND THE INORGANIC TRINITRIDES.*

By I. M. DENNIS and A. W. BROWNIE

Continued from p. 1741.

I. HISTORICAL (continued).

3. Properties and Reactions of Hydronitric Acid and the Inorganic Trinitrides.

THE properties of anhydrous hydronitric acid have been described by Curtius and Radenhausen (*Journ. Prakt. Chem.*, [2], xliii., 207). They have also described the action of a 7 per cent aqueous solution of the acid upon different metals (*Ber.*, xxxiii., 3023). It acts upon metallic iron, zinc, copper, aluminium, and magnesium with vigorous evolution of hydrogen, while a more concentrated solution appears to attack even gold and silver. Curtius and Risson found that in aqueous solution the acid is very slowly decomposed by boiling with moderately dilute mineral acids, but remains unchanged on boiling with pure water (*Journ. Prakt. Chem.*, [2], lviii., 261). During distillation practically all of the acid comes over with the first quarter of the liquid, leaving behind a very dilute solution, which distils unchanged. Aqueous solutions of the acid, even when very dilute, may be kept in stoppered glass bottles indefinitely without decomposition. In concentrated

* From the *Journal of the American Chemical Society*, xxi., No. 6.

aqueous solution it is, however, dangerously explosive (Curtius, *Ber.*, xxiii., 3023).

Ostwald determined by measuring the electrical conductivity of hydronitric acid that it was slightly stronger than acetic acid. His experimental data seem to be inaccessible. Two other investigators almost simultaneously repeated his work. Hantzsch found that the conductivity increased with the temperature (*Ber.*, xxxii., 3066), West measured the conductivity of the acid and of its sodium salt (*Journ. Chem. Soc.*, lxxvii., 705). He finds the strength of the acid at 25° to be slightly greater than that of acetic acid, and about one-seventieth that of hydrochloric acid.

In 1895, Peratoner and Oddo examined the gaseous products obtained by the decomposition of certain compounds of hydronitric acid in the hope of finding argon in case this should be polymeric nitrogen (*Gazz. Chim. Ital.*, xxv., II., 13; *Chem. Centrbl.*, xc., 2, 864). Only traces of argon were found, coming probably from the air dissolved in the solutions.

This subject was further studied by Szarvasy (*Journ. Chem.*, Soc., lxxvii., 603).

See also Peratoner and Oddo (*Gazz. Chim. Ital.*, xxx., II., 95; *Chem. Centrbl.*, 1900, II., 660).

With regard to the structure of hydronitric acid, three lines of evidence tend to support the current belief that the compound contains a closed ring composed of three nitrogen atoms, and has the structural formula—

1. Fischer (*Liebig's Ann. Chem.*, xc., 67) showed that phenyltrinitride (diazobenzenimide) has the structure—

which had already been suggested by Kekulé (*Lehrbuch*, iii., 230). And from this, by the saponification with alcoholic potassium hydroxide of an appropriate substitution product (see reference to Nöling's work above), potassium trinitride is obtained. 2. Dennis and Doan (*Journ. Am. Chem. Soc.*, xviii., 970) found that the decomposition of thalous trinitride in a current of hydrogen yielded both ammonia and nitrogen, which may be expressed—

3. Erdmann suggests that the formation of hydronitric acid by the method of Wislicenus is proof of its structure (*Lehrbuch d. Anorg.*, 2te Auf., p. 190).

In opposition to the foregoing is the belief of Armstrong (*CHEMICAL NEWS*, lxxvii., 153), based upon a study of the optical properties of the acid, that it may be an unsaturated compound with the formula—

Mendeleeff ("Principles of Chemistry," 2nd Eng. ed., vol. i., p. 267) regards hydronitric acid as being theoretically derived from secondary ammonium orthonitrate, by the abstraction of 4 molecules of water, as follows:—

From the corresponding primary salt, nitrous oxide is considered to be derived, and ammonium trinitride from the tertiary salt by a similar theoretical process. It may not be out of place to mention here that orthonitric acid, predicted years ago by Mendeleeff, has recently been made by Erdmann (*Zeit. Anorg. Chem.*, xxxii., 431).

Berthelot and Matignon (*Comptes Rendus*, cxiii., 672),

and Bach (*Zeit. Phys. Chem.*, ix., 241) have almost simultaneously determined the thermochemical data for hydronitric acid.

Details concerning the explosive character of the salts of hydronitric acid will be found in the articles of Curtius, Dennis and Benedict, Dennis and Doan, and Berthelot and Vieille (*Ann. Chem. Phys.*, [7], ii., 339).

Hydronitric acid and its salts have a pronounced toxic effect upon living organisms. When the fumes of the acid are inhaled, even in very small amounts, they produce a characteristic headache and dizziness. The effect upon certain mammals of the subcutaneous injection of small doses of the sodium salt, is the production of spasms, and symptoms of heart and lung paralysis (Loew, *Ber.*, xxiv., 2947). In the case of bacterial life, growth is prevented (Schattenfroth, *Arch. für Hyg.*, xxvii., 231).

(To be continued.)

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Ordinary Meeting, Wednesday, November 16th, 1901

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

PROFESSOR P. C. RAY was formally admitted a Fellow of the Society.

Certificates were read for the first time in favour of Messrs. William Frederick Arnaud, A.I.C., 17, Maddox Street, W.; George Douglas Clarkson, Ash House, Mirfield, Yorks.; Samuel George Eade, 10, Eagle Street, Port Talbot, S. Wales; Carl Richard Hennings, Ph.D., 19, St. Dunstan's Hill, E.C.; Tudor Foulkes Jones, B.Sc., Bro Dawel, Bangor, North Wales; William Sloan Mills, M.A., Queen's College, Galway; Harold Schreder, Lithgow, New South Wales; Ernest Wheeler, 335, Park Road, Oldham, Lancs.; John Henry Becher Wiggington, Kennington Cross, S.E.

A certificate in favour of the following was authorised by the Council for presentation for ballot under By-law 1:—Gustav Komppa, Ph.D., Polytechnic, Helsingfors.

Of the following papers, those marked * were read:—

*189. "The Isomerism of the Amidines of the Naphthalene Series." (Fifth communication on Anhydro-bases). By RAPHAEL MELDOLA and JOSEPH HENRY LANE.

When 2:4-dinitro-aceto- α -naphthalide is reduced by tin and hydrochloric acid, the aminoamidine (M. and S. ethenylidiaminonaphthalene) has the α -NH constitution (No. I.), and the isomeric base (Markfeldt's), produced when iron and hydrochloric acid are used for reduction, has the β -NH constitution (No. II.). The constitution of the corresponding ethenylidiaminonaphthalenes follows from this result:—

This conclusion has been reached by a comparison of the N-alkylamidines obtained by the direct alkylation of the

ethenylammonaphthalenes with the N-alkylamides prepared synthetically and of known constitution. Thus the N-ethylamide, prepared by the direct ethylation of Prager's base, is identical with the base prepared by reducing the compound No. III., and the isomeric N-ethylamide, obtained by the ethylation of the *meta*-ethenylammonaphthalene (cf. *Ann.* 1903, lxxxiii, 1403), is identical with the base prepared by reducing compound No. IV. and the *ortho*-bromonaphthalene product.

It has thus been shown that the isomerism of the ethenyltriaminonaphthalenes is a case of structural isomerism brought about by a novel and, up to the present time, unique method, namely, the action of different reducing agents on the same dinitro compound. In explanation of this isomerisation, the hypothesis is advanced that one of the reducing agents, probably the iron, effects a fractional reduction of the nitro-groups, while the other reducing agent attacks both nitro-groups simultaneously. The formation of the amidine ring would thus take place in one case under the orienting influence of the NO_2 -group, and in the other case under the orienting influence of the NH_2 -group, and the resulting anhydroses might under these conditions be expected to be isomeric, the intermediate phases being the compounds:—

The investigation is being extended to the benzene series, so as to obtain evidence, if possible, of the intermediate phases.

The transformation of the α -NH-aminoamidine into the β -NH-aminoamidine (*Trans.*, 1903, lxxxiii, 1200) is explained by the temporary saturation of the amidine ring by hydrogen and the subsequent removal of the element in accordance with the scheme—

DISCUSSION.

Dr. LANDER asked whether Professor Meldola had observed tautomeric relationships between the isomeric amidines. The work might be regarded as settling the nature of the so-called "virtual" tautomerism of the open-chain mixed amidines discovered by von Pechmann.

Dr. KOHN inquired whether the author had tried to reduce the dinitro-compound electrolytically. If not, this method might throw some light on the suggested hypothesis of the formation of the two amidines, since the stages observed in the electrolytic reduction of nitro-compounds

were somewhat different from those which obtained with the use of metals and acid.

Dr. DIVERS asked whether the production of one or other aminoamidine, according to the metal employed, might not rather be due to the reducing action of stannous or ferrous chloride than to that of the metal itself. But even although due to the action of the metal, there may be difference in the effect, because the reduction is not caused actually by hydrogen, but by the combined simultaneous action of the metal and the 2:4-dinitroaceto- α -naphthalide on the hydrochloric acid.

Dr. MORGAN remarked that the hypothesis that iron and hydrochloric acid reduced the nitro-groups of 2:4-dinitroaceto- α -naphthalide successively was supported by the known behaviour of this reducing agent towards *m*-dinitro-compounds in the benzene series. The production of *m*-nitraniline from *m*-dinitrobenzene by the action of limited amounts of iron and acid had formerly been patented (D.R.P. 67018). He had likewise found that, in the case of dinitrostyrene, the use of iron and water, with a small amount of acetic or hydrochloric acid as catalyst, led to the production of nitrosesidine, whereas complete reduction to diaminesidine was effected by employing tin and hydrochloric acid.

Quite recently, Meister, Lucius, and Brünig (D.R.P. 151768, *Abstr.*, 1904, i, 943) had obtained 1-acetylaminodiaminonaphthalene from 2:4-dinitroaceto- α -naphthalide by using iron and acetic acid. As the authors assumed that this acetyltriamine was an intermediate product in the formation of one of the two isomeric aminoamidines, it would be of interest to ascertain whether the acetylated base would yield by direct dehydration the isomeride predicted by their theory.

Professor MELDOLA, in reply, stated that both ferrous and stannous chlorides had been tried as reducing agents. The latter gave rise to the M. and S. base, the former was apparently without action under ordinary conditions. Several metals other than tin and iron had been used as reducing agents, and the results were described in the present and in former papers. Thus far, the action of iron in giving rise directly to Markfeldt's base appeared to be unique.

The practical difficulty that presented itself in all the experiments was the great insolubility of 2:4-dinitroaceto- α -naphthalide. This compound was practically insoluble in cold alcohol and acetic acid. With concentrated sulphuric acid as a solvent, there was a danger of the acetyl group being split off. For this reason, electrolytic reduction had not hitherto been attempted. He agreed with Dr. Lander's view that the results arrived at might be regarded as settling the question of the "virtual" tautomerism of the amidines raised by von Pechmann. There seemed to be no tautomeric relations between the isomeric amidines or aminoamidines. The patented process for preparing acetyltriaminonaphthalene referred to by Dr. Morgan had not yet been tried.

*190. "Theory of the Production of Mercurous Nitrite and of its Conversion into various Mercury Nitrates." By PRAFULLA CHANDRA RAY.

Mercurous nitrite is the sole product, other than water, of the immediate action of mercury on dilute nitric acid containing any nitrous acid. In the absence of the latter acid, the former is quite inactive. The formation of the salt may be expressed by the equation $2\text{Hg} + \text{NO} + \text{HNO}_2 \rightarrow \text{Hg}_2(\text{NO}_2)_2 + \text{H}_2\text{O}$, but it is in part converted by nitric acid into nitrate and nitrous acid. At suitable temperatures and in presence of the right proportions of water and nitric acid, a stage is soon reached in which the quantity of nitrite produced by nitrous acid is just balanced by that decomposed by nitric acid. There then ensues for some time a steady accumulation of mercurous nitrite, during which the production of permanent nitrite is due wholly to the nitric acid, as expressed by the equation $2\text{Hg} + 4\text{HNO}_3 \rightarrow \text{Hg}_2(\text{NO}_3)_2 + 2\text{H}_2\text{O}$. So long as this equation is valid, there is present in the

solution an unvarying quantity of nitrous acid, acting, as it were, catalytically. Analyses of portions of the solution drawn off close to the surface of the mercury give support to the foregoing theoretical considerations. When working at 35°, the mercurous nitrite and mercurous nitrate are present in molecular proportion.

The basic constitution of Marignac's mercurous nitrates is traced to the behaviour of mercuric nitrite, which is itself derived from mercurous nitrite (*Trans.*, 1904, lxxxv., 523). The production of hemi-hydroxy-mercurous nitrate is explained by the following equation:—

Two oxy-mercurous nitrates, one orange-yellow and the other lemon yellow, the latter best known through Gerhardt's work, the former a salt obtained by the author, are both traced to their origin from mercurous nitrite through the agency of mercuric nitrite. Direct oxidising action, whether by nitric acid or by air, is demonstrated to be at least unnecessary for the production of the mercuric and mercurous nitrates which result from the prolonged changes occurring in a nitric acid solution of mercury.

*191. "Amidechloroiodides." By GEORGE DRUCE LANDER and HARRY EDWIN LAWS.

When pure dry hydrogen iodide is passed into a solution of benzanilide imidechloride in light petroleum, an amidechloroiodide, probably having the constitution $\text{Ph} \cdot \text{CCl} \cdot \text{NHPh}$, is precipitated as a microcrystalline yellow powder (m. p. 106° with decomposition). A similar result is obtained with the imide chloride of benzo- β -toluide.

With arylamines and sodium alkylloxides, amidines and iminoethers respectively are formed, the chloroiodides first losing hydriodic acid and the imidechlorides then reacting in the usual way. As the iodine atom is not capable of giving reactions of substitution, no direct evidence in support of the given constitution can be adduced, but the compounds are analogous in physical properties and chemical behaviour to Biltz's amideiodides, $\text{RCI}_2 \cdot \text{NH}_2$.

Benzamidedi-iodide, $\text{PhCl}_2 \cdot \text{NH}_2$, can be easily prepared by means of dry hydrogen iodide instead of the concentrated aqueous solution used by Biltz. Benzonitrile is formed from it by the action of alcoholic sodium ethoxide.

192. "A New Synthesis of isoCaprolactone and certain Derivatives." By DAVID TREVOR JONES and GEORGE TATTERSALL.

isoCaprolactone may be easily obtained by the action of magnesium methyl iodide on ethyl laevulate in ethereal solution, the yield being 30 per cent.

On treating isocaprolactone with phosphorus pentabromide in the cold and pouring the product into alcohol, ethyl γ -bromoisocaproate, $(\text{CH}_2)_3 \cdot \text{CBr} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$, is formed, which decomposes on distillation.

Ethyl γ -methylallylacate, $\text{CH}_2 \cdot \text{CMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$, obtained by treating ethyl γ -bromoisocaproate with diethyl aniline at 140° for ten minutes, is a fragrant mobile liquid boiling at 85° under 20 m.m. pressure.

γ -Methylallylacetic (γ -methyl- Δ^1 -pentenoic) acid, $\text{CH}_2 \cdot \text{CMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$, produced when the preceding ester is hydrolysed with aqueous caustic soda, is a liquid with a pungent odour; it is volatile in steam and polymerises on distillation.

193. "The Influence of Substitution in the Nucleus on the Rate of Oxidation of the Side-Chain." Part II. Oxidation of the Halogen Derivatives of Toluene." By JULIUS BEREND COHEN and JAMES MILLER.

The authors have studied the behaviour of the isomeric chlorobromo- and dibromo-toluenes, and the following

table contains a synopsis of the results obtained with these substances, and also with the dichlorotoluenes (compare *Trans.*, 1904, lxxxv., 174), the compounds on the left being least, those on the right most, rapidly oxidised. The bracket indicates an approximately equal rate of oxidation.

Cl·Cl ..	3·5	2·5	2·6	2·3	2·4	3·4
Cl·Br ..	3·5	2·5	2·6	2·3	2·4	3·4
Br·Cl ..		2·5		2·3	2·4	3·4
Br·Br ..	3·5	2·3	2·5	2·6	2·4	3·4

The order of oxidation is the same in all three series with the exception of the 2:3-dibromotoluene, which follows the 3:5- instead of the 2:5- and 2:6-compounds, as in the other two series.

A comparison of the pairs of chlorobromo-compounds with reversed positions of the halogens indicates that the compound in which bromine occupies the meta-position is the less rapidly oxidised of the two.

The dibromotoluenes are in all cases less rapidly oxidised than the dichlorotoluenes, and where bromine is in the meta-position the retarding action is much more pronounced than in the other cases.

The position occupied by the chlorobromotoluenes as regards the rate of oxidation is not always midway between the other two series (the dichloro- and dibromo-toluenes), but appears at first sight to be quite irregular; it may be accounted for by the fact that the three monobromotoluenes are much more rapidly oxidised than the three monochlorotoluenes, and if, as appears probable, two different halogens interfere less with each other's individual influence than two similar halogens, the apparent irregularities vanish. The problem is, however, thereby rendered more complex.

The authors propose to introduce the word "isotopic" (*isos*, equal; *τόπος*, place) to indicate similar compounds substituted in the same positions. Thus the 2:3-dichloro-, 2:3-chlorobromo-, 3:2-chlorobromo-, and 2:3-dibromo-toluenes would be "isotopic" substances.

194. "The Halogen Derivatives of Naphthacenequinone." By SAMUEL SHROWDER PICKLES and CHARLES WEIZMANN.

In the systematic investigation of the halogen derivatives of naphthacenequinone, $\text{C}_{18}\text{H}_{10}\text{O}_2$, the preparation of these compounds by direct bromination or chlorination is not advisable, inasmuch as the separation and identification of the products would be a matter of considerable difficulty. The authors have succeeded in obtaining a monochloro-derivative, in which the position of the chlorine atom is defined by first treating hydroxynaphthoyl-*o*-benzoic acid with phosphorus pentachloride, thus obtaining a chloronaphthoyl-*o*-benzoic acid. On treating this acid with concentrated sulphuric acid, water is eliminated and chloronaphthacenequinone is produced.

195. "The Constitution of Pyrazolidone Derivatives: β -Phenylazoisovaleric Acid and β -Phenylhydrazidobutyric Acid." By BERTRAM PRENTICE.

When 1-phenyl-3:3-dimethyl-5-pyrazolidone (m. p. 74–75°) is hydrolysed with barium hydroxide, β -phenylazois-

valeric acid (m. p. 57—58°) is produced (Ber., 1896, cxcvii., 272). When treated with reducing agents in acid solution, β -phenylazo-valeric acid yields 1-phenyl-3,3-dimethyl-5-pyrazolidone, which is formed by the condensation of the intermediate β -phenylhydrazido-valeric acid.

1-Phenyl-3-methyl-5-pyrazolidone, prepared according to Knorr and Duden's method (Ber., 1893, xxvi., 103) was also hydrolysed, and yielded 5-8-phenylhydrazidobutyric acid, $C_6H_5 \cdot NH \cdot NH \cdot CH(CH_3) \cdot CH_2 \cdot CO_2H$ (m. p. 96—97°), an unstable substance with strong reducing properties, which on fusion loses 1 molecule of water, and becomes converted into 1-phenyl-3-methyl-5-pyrazolidone (m. p. 81—85°).

196. "Preliminary Notice of some Condensations of Phenanthraquinone with Ketonic Compounds." By FRANCIS ROBERT JAPP and JAMES WOOD.

Very few condensations of this class have hitherto been studied, and in these only alkaline condensing agents have been employed; but in many cases such agents give no result. The authors find, however, that acetic anhydride containing a little sulphuric acid frequently brings about the desired reaction.

Thus a mixture of phenanthraquinone and acetophenone yields, with this reagent—slowly at the ordinary temperature, more rapidly at 40°—3-acetoxy-2-phenyl-4:5-diphenyl-1,4-dioxane.

which crystallises from benzene in slender needles (m. p. 232°).

When phenanthraquinone and ethyl benzoylacetate, on the other hand, ethyl diphenylenedibenzoylmalonate (ethyl β , β' -diphenylene- α , α' -dibenzoylbutadiene- α , α' -dicarboxylate),—

is obtained, the acetic anhydride in this case furnishing no part of the resultant molecule. This substance crystallises from benzene in rectangular plates with bevelled edges. It softens and almost melts between 170° and 174°, but immediately re-solidifies, finally melting sharply at 223°. This phenomenon is due to the transformation of the condensation compound into an isomeride, which crystallises from acetic acid in slender needles melting at 223.5°.

Under the foregoing conditions, phenanthraquinone also yields condensation products with ethyl acetacetate, ethyl malonate, and analogous compounds.

The authors wish to reserve the study of these various condensations.

197. "The Decomposition of Ethylene Iodide under the Influence of the Iodide Ion." By ARTHUR SLATOR.

The following is a summary of the results obtained:—

1. Ethylene iodide in aqueous-alcoholic solution decomposes quantitatively in the presence of potassium iodide, yielding ethylene and iodine.

2. The velocity of reaction is proportional to the concentration of ethylene iodide, and also to that of the iodide ion, showing that the potassium iodide takes some direct (or catalytic) part in the reaction. The temperature quotient for 10° is 2.5.

3. This reaction is distinct from that between ethylene iodide and sodium thiosulphate, for the two reactions may be superimposed without any great mutual interference.

4. The rate of liberation of iodine from solutions of methyl iodide, isopropyl iodide, and ethyl iodoacetate is accelerated by the addition of potassium iodide.

5. Ethylene bromide in presence of potassium iodide liberates iodine according to the equation, $C_2H_4IBr + KI = C_2H_4I_2 + KBr$.

6. The reaction velocity is proportional to the concentration of the bromide and also to that of the potassium iodide, and the temperature quotient for 10° is 2.45.

Ethylene iodide is probably not an intermediate product in the reaction. The iodide decomposes about three times as fast as the bromide.

198. "The Spectrum Green's Attributed to Chlorophyll, and its Relation to the Spectrum of Living Green Tissues." By WALTER NOEL HARTLEY.

The author formerly showed (Trans., 1891, lix., 106) that the alcoholic extract of fresh green leaves and also the alcoholic extract of dried leaves do not give the same absorption spectrum as the material in the living leaf when examined under normal conditions. This difference was believed to be due either to the formation or the occurrence of acid in the extract and in the dried leaves, this acid effecting chemical changes in the colouring matter. The same changes in the spectrum could be brought about in the living leaf in an oxidising atmosphere under the action of intense sunlight, and these are conditions which would lead to the formation of an acid.

Marchlewski and Schunck (Trans., 1900, lxxvii., 1080) cast doubt on the accuracy of the author's observations, and more particularly on the efficiency of the process described for extracting the bluish-green colouring matter. Sorby's "blue chlorophyll," in an unchanged condition from an alcoholic extract of green leaves. The author therefore found it desirable to have the process re-examined by an independent observer, and subsequently he repeated the experiments himself. Further measurements of spectra are recorded which confirm the accuracy of the original observations.

199. "Studies on Comparative Cryoscopy. Part II. The Aromatic Acids in Phenol Solution." By PHILIP WILFRED ROBERTSON.

As in the case of the fatty acids, an intimate relationship is shown between the association and the velocity of esterification; those acids which are most difficult to esterify associate the least.

Substitution in the ortho-position with respect to the carboxyl group reduces the "rate" of association. The substituent groups or atoms may be arranged in the following order:—OH, CH₃, Cl, Br, NO₂. The lighter groups exert only a slight influence, but there is a marked diminution in the case of the heavier groups.

In the case of acids containing two ortho-substituents, however, there is practically no association, whether the substituent is heavy or light. Compounds of this nature are characterised by the fact that they yield esters only with the greatest difficulty, whereas the velocity of esterification of the ortho-substituted benzoic acids is dependent on the weight of the substituting group or atom.

Substitution of the nitro-group in the meta-position still causes a reduction in the "rate" of association, but a lighter group, like methyl, has no influence in this position.

The hydroxylic and dibasic acids are characterised by their sparing solubility in phenol.

200. Isomeric Change of Diacylanilides into Acylaminoketones. Transformation of Dibenzoylaminobenzophenone into 1-Benzoylaminobenzophenone. By FREDERICK DANIEL CHATTAWAY and WILLIAM HENRY LEWIS.

It has recently been shown (Trans., 1904, lxxxv., 386, 499) that diacyl derivatives of aromatic amines can undergo an intramolecular re-arrangement whereby an acyl group leaves the nitrogen and enters the nucleus in an ortho- or a para-position with respect to this element. The transformation of such diacylaminobenzophenone derivatives can progress beyond the first stage, so that two groups may enter the ring in positions probably ortho- and para- to the nitrogen. The isolation of 1-amino-2:4-dibenzoylbenzene from the

product obtained by heating aniline (1 mol.) with benzoyl chloride (3 mols.) were described.

Erratum.—P. 275, col. 2, line 30 from top, after "permanganate" insert "in the presence of potassium persulphate."

THE FARADAY SOCIETY.

Wednesday, November 23rd, 1904.

Mr. W. R. COOPER, in the Chair.

THE Ninth Ordinary Meeting was held at the Institution of Electrical Engineers.

The minutes of the previous meeting were duly confirmed.

THE CHAIRMAN moved that the hearty congratulations of the Society be tendered to the President, Sir Joseph Wilson Swan, on the occasion of the recent dignity which had been conferred upon him by the King. The motion was carried unanimously amid applause.

Professor L. KAHLBERG, Ph.D., presented a paper on "*Recent Investigations bearing on the Theory of Electrolytic Dissociation*," which, in the absence of the author, was read in abstract by the Secretary.

In creating the theory of electrolytic dissociation the phenomena of actual electrolysis have played a minor part. It has rather been based on the observation that for many aqueous solutions the molecular conductivity increases with the dilution, and that the osmotic pressure, lowering of freezing-point, and similar physical constants are abnormally great. The hypothesis is thus virtually connected with van 't Hoff's theory of dilute solutions which it generalises in the form $PV = iRT$, where i , the so-called degree of dissociation, is unity for non-electrolytes, and greater than one for electrolytes. The author is of opinion that the theory is supported by isolated facts only.

Comparisons of the molecular conductivities with the freezing-points at 0° and boiling-points at 95° were made by the author in 1901, with typical solutions of electrolytes and non-electrolytes, and no such connection between those quantities as demanded by the theory was found.

According to the theory, molecular conductivities should increase with the volume, but in practice that is often not the case.

According to the Nernst-Thomson rule, dissociation is caused by the high specific inductive capacity of the solvent, but cases are cited, such as liquid hydrocyanic acid, where a higher dielectric constant than water has accompanied by lower conducting—and therefore ionising—power.

Additive properties are not a valid argument in favour of the theory, because they occur in quantities such as molecular heats and molecular refractions, where ionisation is out of the question.

The colours of solutions have been attributed to the free ions present, but copper, nickel, and cobalt oleates are insulators, and yet bear the characteristic colours of the supposed metallic ions.

Instantaneous reactions sometimes occur between insulating solutions, and hence cannot be regarded as taking place between the free ions present.

A strong argument against the hypothesis is that it cannot be harmonised with the law of mass-action. The agreements obtained by Ostwald in his application of the dilution law to solutions of weak organic acids are only very rough, and to electrolytes *par excellence* it cannot be applied at all. Rudolphi's and van 't Hoff's amended formulae are purely empirical.

The power of coagulating colloids has been ascribed to free ions, but such power is not confined to solutions of electrolytes.

It is in the realm of non-aqueous solutions that the theory proves especially important. We now know of such solutions that conduct electricity even better than aqueous

solutions, and yet yield higher molecular weights than those computed from the formulae of the solutes. The researches of Walden on liquid sulphur dioxide are quoted as being particularly conclusive.

The theory has been applied to fused salts. The author questions the validity of such application to what are practically 100 per cent solutions; the hypothesis is avowedly only strictly true for infinitely dilute solutions.

Professor Kahlenberg does not think the hypothesis can be retained even in a modified form. It must give way to a conception which takes into account the affinity—of the same nature as chemical affinity—between solvent and solute. "*The processes of solution and chemical action are identical in character, and chemical compounds are merely the cleavage pieces of solutions placed under special stress or duress represented by the so-called purifying processes.*" Thus chemical action is merely a special case of solution, and the process of solution is the general case of the interaction of bodies resulting from their specific attractions for one another. A dilute solution is merely a limiting case. The abnormal values of molecular weights of substances in solution as determined by change of vapour tension, freezing- or melting-points, is merely a measure of the affinity between solute and solvent, and has nothing to do with any supposed dissociation; the calculation of molecular conductivities is founded upon the erroneous supposition that the solvent plays no part in the conduction. Recent determinations of osmotic pressures by the author have similarly shown that these depend on the nature of both membrane and liquids, and are by no means in accordance with the requirements of the gas laws. Here, again, as in solutions, *affinity* is the determining quantity.

Mr. W. C. D. WHETHAM, in a written communication, pointed out that the problem of the nature of solution was independent of the difference between electrolytes and non-electrolytes, which was all the theory attempted to explain. The ions must be conceived as being free from each other, not from all chemical combination, in order to explain the observed phenomena of conduction.

Professor ABEGG also sent in a written communication. Professor Kahlenberg's reasons for doubting the theory are merely facts which cannot be explained by the Arrhenius theory alone. The latter explains the behaviour of dilute aqueous solutions, where the non-ionised molecules are, as a rule, not associated, and not cases where association occurs, such as in non-aqueous solutions. The author further overlooks the fact that conductivity depends on the mobility of the ions, as well as on the degree of ionisation. The theory can be harmonised with the law of mass action, as the work of Rothmund and Drucker and Jahn has shown.

Dr. G. RUDORF referred to the question of the colour of solutions, and showed that on the assumption that the molecule of copper sulphate has nearly the same light-absorbing properties as the ion, all difficulties disappear. The theory quite explains the reactions mentioned in benzene solution, if only very few ions are assumed to be present.

Dr. T. M. LOWRY said that Prof. Kahlenberg's criticisms were mostly expended on a theory which was not the dissociation hypothesis as conceived to-day. The theory does hold good for concentrated solutions, only we are not yet able to measure the degree of ionisation in such cases. The gas laws are not quite true for moderately dilute solutions, because some of the molecules of the solutes are in combination, and not free. He dealt at length with the various points raised by the author.

Dr. H. BORN showed that Prof. Kahlenberg's capital mistake was that he attacked everything that had ever been said or done with the theory. He ignored recent modifications of it that the ideas of hydrolysis, complex ions, and association have caused.

Dr. H. SAND (communicated) dealt with the differences between the theory of Clausius and that of Arrhenius, and discussed some of the approximate assumptions that lead

to numerical disagreements in the applications of the latter.

Dr. C. H. DESCH discussed Prof. Kahlenberg's experiments with copper oleate in benzene solution, and described some experiments of his own bearing on the subject. He thought the difficulties raised by non-aqueous solutions very serious ones.

Mr. F. S. SMITHS drew attention to the theory of Traube, which gave numerical expression to some of the conceptions of solution apparently held by Prof. Kahlenberg, and explained the Arrhenius coefficient i in terms of the affinity between solute and solvent.

Mr. F. J. BRISLEE, M.Sc., communicated a paper entitled "The Potential of the Hydrogen Electrode," which was read by Dr. P. M. PERKIN.

Measurements of the potential of the combination

show different results when the oxygen electrode is charged with oxygen electrolytically, or charged by passing oxygen gas through the liquid. Experiments were made to determine the influence of hydrogen peroxide, ozone, and persulphuric acid upon the oxygen potential. The results obtained showed that the addition of hydrogen peroxide lowered the oxygen potential, while addition of ozone and potassium persulphate raised it.

By employing platinum electrodes of extreme thinness (prepared by depositing platinum on glass), the same potential of the combination was obtained independently of the method employed for charging the electrodes. This potential showed a good agreement with that calculated from the Helmholtz formula.

Mr. H. L. JOLY, referring to the effect of persulphates, said that in accumulators it had been proved that their presence did not account for the rise of E.M.F. on charge.

by the action of potash, which converts this acid and its derivatives into crotonic compounds.

Oxidation of Acetol.—André Kling.—The author describes the action of various classes of oxidising agents upon acetol, and discusses the results of his experiments.

The Formation of Formic Aldehyde in the Combustion of Tobacco.—A. Trillat.—Already noticed.

MISCELLANEOUS.

Royal Institution.—The following are the Lecture Arrangements at the Royal Institution before Easter:—

A Christmas Course of Lectures (experimentally illustrated and adapted to a juvenile auditory) on "Ancient and Modern Methods of Measuring Time," by Mr. Henry Cunynghame.

Professor L. C. Miall, Fullerian Professor of Physiology, R.I., six lectures on "Adaptation and History in the Structure and Life of Animals."

Professor Karl Pearson, three lectures on "Some Recent Biometric Studies."

Professor W. E. Dalby, two lectures on "Engineering."

Mr. A. H. Savage Landor, two lectures on "Exploration in the Philippines."

Mr. Churton Collins, two lectures on (I.) "The Religion of Shakespeare." (II.) "The Philosophy and Significance of 'The Tempest.'"

Professor W. Schlich, two lectures on "Forestry in the British Empire."

Mr. J. H. Teall, two lectures on "Recent Work of the Geological Survey."

Professor H. H. Turner, three lectures on "Recent Astronomical Progress."

Professor R. Meldola two lectures on "Synthetic Chemistry" (Experimental).

Sir Alexander Mackenzie, three lectures on the "Bohemian School of Music" (with Musical Illustrations).

Mr. D. G. Hogarth, two lectures on "Archæology."

Professor J. J. Thomson, three lectures on "Electrical Properties of Radio-active Substances."

The Right Hon. Lord Rayleigh, three lectures on "Some Controversial Questions of Optics."

The Friday Evening Meetings will begin on January 20, when a Discourse will be delivered by Professor Sir James Dewar on "New Low Temperature Phenomena." Succeding Discourses will probably be given by Dr. E. A. Wilson, Mr. Cecil Smith, Mr. J. W. Gordon, Professor H. Marshall Ward, Chevalier G. Marconi, Professor J. J. Thomson, Sir Squire Bancroft, Professor G. H. Bryan, Professor J. Wright, Professor T. C. Allbut, the Right Hon. Lord Rayleigh, and other gentlemen.

Separation and Isolation of Reducing Sugars by means of Hydrazine.—Emil Votocek and R. Vondracek.

—By the reaction of sugar hydrazones with aromatic hydrazines the reducing sugars can be identified, *i.e.*, such sugars can be precipitated systematically from mixtures by application of suitably chosen hydrazines. By preliminary experiments (colour reactions, distillation with hydrochloric acid, &c.), it is first determined which series of sugars the syrup to be analysed contains, *e.g.*, whether hexose and pentose, hexose and methylpentose, pentose and methylpentose, &c., are present. Then the total sugar is determined by Fehlings' solution, and the syrup diluted with water till it contains 5 per cent of sugar. The equivalent weight of a suitable hydrazine or its acetate is then added to the diluted solution, the hydrazine thus formed is removed, and another aromatic hydrazine added direct to the mother-liquor to convert the second sugar into hydrazine (or osazone). The hydrazine is then identified by its melting-point. This process can be repeated for a third sugar. *Ber.*, xxxviii., No. 15.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise stated.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. CXXXIX., No. 19, November 7, 1904.

The Effect of Low Temperatures upon Dyes.

—Jules Schmidlen.—The temperature of liquid air does not affect dyes when in the solid state, nor when fixed upon silk or woollen material. The colour of alcoholic solutions of some dyes is weakened at the above temperatures; this is particularly noticeable with the rosanilines, in whose solutions a beautiful green fluorescence becomes visible as the colour disappears. Probably at ordinary temperatures the fluorescence is masked by the colour.

Heat of Combustion of Triphenylmethyl and of some Derivatives of Triphenylmethane.—Jules Schmidlen.—The results of a number of experiments are given.

Preparation of Aurous Iodide by the Action of Iodine on Gold.—Fernand Meyer.—Already noticed.

β -Bromobutyric Acid.—M. Lespieau.—The amide of β -bromobutyric acid was obtained by saturating allyl cyanide with hydrobromic acid gas in the cold. When this amide was saponified by warm hydrobromic acid, an acid was obtained which melted at 17 – 18° and boiled at 122° under 16 m.m. pressure. The formula by analysis is $\text{C}_4\text{H}_7\text{BrO}_2$; melting-point by cryoscopic methods 166° . The melting- and boiling-points of this acid and its derivatives differ from those of the α - and γ -acids, therefore the bromine must be in the β -position. This is further proved

Royal Institution.—A General Monthly Meeting of the Members of the Royal Institution was held on the 5th inst., Sir James Crichton-Browne, M.D., F.R.S., Treasurer and Vice-President, in the Chair. Colonel C. W. Carr-Calthrop, Mr. Cecil Hanbury, Dr. E. Graham Little, Mr. Hugh Makins, and Mr. E. Reinach were elected Members.

MEETINGS FOR THE WEEK.

MONDAY, 12th.—Society of Dyers and Colourists, 8. "Bleaching Agents, and the Methods of Application," by F. W. Walker. "Application of Sulphide Colours in the Dyeing of Chrome Leather," by Dr. W. Epstein.

WEDNESDAY, 14th.—Chemical, 5.30. "Hydrolyses of Ammonium Salts," by V. H. Veley. "Viscosity of Liquid Mixtures" (Part II.), by A. E. Dunstan.

"The Diazo-reaction in the Diphenyl Series—Part II., Ethoxybenzidine," by J. C. Cain. "The Sulphate and the Phosphate of the Dimercurammonium Series," by F. C. Ray. "Method for the Direct Production of certain Aminoazo-compounds," by R. Meldola and L. Eynon.

Society of Arts, 8. "The Patent Laws," by Chas. D. Abel.

RESEARCHES UPON THE CANON DIABLO METEORITE.

By HENRI MOISSAN.

A CERTAIN amount of work has been done upon the native iron found in Arizona, near the Canon Diablo. Koenig, then Mallard in 1892, noticed small fragments in it, which were hard enough to scratch corundum. In the same year Friedel, after having dissolved a small portion of the iron in hydrochloric acid, pointed out that it contained black diamonds. Finally, in 1893, we showed that certain fragments of this native iron, or meteorite, contained transparent diamonds.

Our first research was made upon a very small fragment of Canon Diablo iron, weighing only 4 grms.; it contained, however, one unmistakable point of extreme hardness, upon which a steel grindstone had no effect. We have since had the opportunity of continuing our work upon a much larger specimen weighing 183 k.grms., which was kindly placed at our disposal by M. Wallerant, Professor at the Sorbonne.

The rough irregular surface of this well-known meteorite is of a dark brown colour, and has a shivelled appearance. It contains those characteristic external cavities which, according to Daubrée, would be produced by the escape of a gas at high pressure.

The first process was to cut up the block of iron in order to examine the interior. This was done by M. Paul Regnard by means of a long steel ribbon saw. The meteorite was put in a carriage which could be moved forward slowly, while the ribbon saw was moved by four pulleys driven by steam. Under these conditions the saw penetrated easily enough to a depth of several centimetres within the block; but then the blade seemed to meet some very hard body, and no further headway was made. After some time it became necessary to change the saw and to make the carriage move more quickly. The work was continued for several hours without much result. Then suddenly the resisting object seemed to break, or else the blade passed round the obstacle, and was able again to move forwards. The sawing then began again regularly, but soon stopped as before, and in this way no fewer than twenty days were occupied in cutting this specimen of Canon Diablo iron into two parts. The sawed surface measured about 626 square c.m.; the left side seemed to be homogeneous, and was the colour and lustre of iron; on the right side there were five large marks of elliptical shape and three small ones.

These spots were of a grey or black colour. The major axis of the ellipse in the case of one measured 2.3 c.m., and the minor axis 2 c.m. Another had a major axis of 3.4 c.m. and a minor axis of 2.1 c.m. The little spots were practically circles of 1 c.m. diameter. Some of these spots were joined by broken irregular lines, or by fissures filled with a black material. The three largest spots were dark in colour, the others were grey. Certain of these spots were surrounded by a black material which formed a pad between the metal and the ellipse.

It was clear that it was these spots which had offered such a strong resistance to the saw, because round each of them the surface of the metal was not plane, but was furrowed, showing that the saw had met an obstacle and had moved out of the vertical to get round it.

By comparing this section of the block with specimens of the same origin in New York Museum, we have satisfied ourselves that this is the general aspect of the interior of

Canon Diablo iron. Also, by the kindness of Dr. Harvey, of the New York Natural History Museum, we have been able to compare it with sections of other meteorites, such as the Toluca meteorite, and we have found that they all present the same appearance.

When examined by the microscope the metallic surface seemed to be homogeneous, and the elliptical spots clear and crystalline.

The fissures joining the spots were filled with a black substance which had apparently been compressed. In the envelope of several of the ellipses masses of brilliant metallic crystals were found, but at other places, both round the ellipses and in the fissures, there were black masses of very finely grained structure. To analyse the meteorite chemically 53 k.grms. were dissolved in pure hydrochloric acid. It was immediately evident, as we have already shown, that the iron was not homogeneous, for it was attacked very irregularly by the acid. Where the sawed surface had been plane, raised striae quickly appeared, forming a system of slightly undulating parallel lines, cut, from place to place, by similar perpendicular lines.

But the following fact seemed the most interesting to us:—The ellipses turned out to be the sections of nodules, which quickly disaggregated in the hydrochloric acid and fell to the bottom of the vessel, leaving cavities with sharp edges, resembling those found on the outer surface of Canon Diablo iron and other meteorites.

The hydrogen set free during this reaction contained hydrocarbons, sulphuretted hydrogen, and phosphoretted hydrogen.

The analysis was divided into three parts:—(1) Analysis of the metal; (2) of the nodules; (3) of the carbon.

1. Analysis of the Metal.

We found the metal to be an alloy of iron and nickel containing small quantities of phosphorus, silicon, sulphur, and magnesium; there were also traces of cobalt, which have not hitherto been noticed. Thus the metallic part of Canon Diablo iron is far from being homogeneous. Certain fragments taken from the exterior contained iron and nickel in the following proportions for 100 parts of the mineral:—Iron, 95.64; nickel, 1.66. Iron, 95.26; nickel, 2.56. Iron, 94.03; nickel, 3.61. Iron, 96.31; nickel, 1.83. A specimen of density 7.703 from the inside of the meteorite gave the following figures on analysis:—

Iron	95.370
Nickel	3.945
Phosphorus	0.144
Substances insoluble in boiling HCl	0.260
Silicon	traces
Sulphur	traces
Carbon	not determined

This specimen clearly contained carbon, and being taken from near a nodule it was fairly rich in phosphorus. Specimens taken from parts at some distance from the nodules were found to be much poorer in phosphorus and carbon.

2. Analysis of the Nodules.

The nodule was separated from the block by means of a chisel and hammer.

In this nodule there were both metallic and black amorphous fragments. No weight was lost by heating it in a little tube to 700° C. When attacked by hydrochloric acid a large amount of sulphuretted hydrogen was set free. In the acid solution we found a large amount of iron, some nickel, and a very small quantity of cobalt, which was recognised by the borax bead test, and by the formation of a double nitrite of cobalt and nickel. The solution also contained phosphorus, silicon, calcium, and magnesium in small quantities. The insoluble portion contained silica, amorphous carbon, graphite, and black and transparent diamonds. The following figures were given by the quantitative analysis of a nodule:—

Iron	66.95	67.51
Nickel	1.93	1.77
Cobalt	traces	
Sulphur	22.15	19.91
Phosphorus	2.37	2.30
Silicon	small quantity	
Magnesium	traces	
Carbon	1.96	

Analysis of the Residue Insoluble in Hydrochloric Acid.

—The following was an analysis of the residue remaining after the 53 k.grms. previously mentioned had been treated with hydrochloric acid. After the treatment with acid, a residue remained in the bottom which, when dried, weighed about 800 grms. It consisted of a coarse powder containing brilliant needles and cubes. We separated these by use of a forceps.

	Needles.			Cubes.
	1.	2.	3.	
Phosphorus	26.97	25.95	25.95	26.46
Iron	71.63	72.15	73.51	72.43
Nickel	traces			
Carbon	traces			

There was no doubt about the presence of carbon, for after treatment with aqua regia a light insoluble deposit remained, which burnt in oxygen with the formation of carbon dioxide.

The crystals apparently consist of a phosphide of iron of formula P_2Fe_3 , and which theoretically would contain 26.95 per cent of phosphorus and 73.05 per cent of iron. The variations in the analyses of this crystallised phosphide are explained by Mr. Stead's work, in which he showed that phosphides obtained from steels containing phosphorus vary in composition.

This crystallised compound is fairly abundant, both in the striae of the nickel and iron alloy and in the neighbourhood of the nodules.

Presence of Carbon Silicide.—In the residue which remained after treatment with concentrated hydrofluoric acid and boiling sulphuric acid we found the characteristic green hexagonal crystals of carbon silicide. This is the first time that carbon silicide has been met with in nature, although it was obtained accidentally by M. Lebeau when he was preparing nickel silicides by the electric furnace.

3. Study of the Carbon.

The carbon, which is found in small and variable quantity in the alloy of nickel and iron far from the nodules, is partially converted into hydrocarbons when the metal is treated with hydrochloric acid, so that the black residue that remains only contains a portion of the total amount of carbon present in the Canon Diablo iron. The residue which remained after the iron had been attacked by acid weighed about 800 grms., and analysis showed that it contained 5.04 per cent of carbon.

This carbon was present in several different forms. Some of the fragments found in the residue were about $\frac{1}{4}$ of a c.c. in size, and were of a very irregular shape. The following varieties were met with:—

1. A light impalpable powder of a variable brown colour, which resulted from the decomposition of the carbon compounds contained in the iron nickel alloy.

2. Carbon occurring in jagged slender fragments of a light colour, and which seemed to have been agglomerated by pressure.

3. Graphite, which was recognised by transforming it into graphitic oxide. This graphite is very rarely crystallised, but is almost always amorphous, and yields a dark brown graphitic oxide.

4. Smooth black diamonds. These were abundant in the residue, but were always very small.

5. Transparent diamonds in the form of octahedrons with rounded edges.

Sawdust of the Meteorite.—All the above qualitative work was verified by an analysis of the sawdust which

contained both the metal and the nodules. In it we found iron phosphide, carbon silicide, and the three varieties of carbon.

In conclusion, Canon Diablo iron contains the three forms of carbon—amorphous, graphitic, and crystalline. The latter consists both of black and transparent diamonds. But the interesting result of this work is that the diamonds are found to be surrounded by a sheath of carbon, and that they occur round the nodules of the Canon Diablo iron, nodules which contain silicon phosphorus, and above all sulphur.

To explain the formation of these nodules in the midst of the mass of iron we must have recourse to the interesting experiments of Mr. Stead. He has shown that if carburetted iron is kept at about 700° C. the iron carbide makes its way through the mass and collects in nuclei. This takes place just below and very near 700° C., and if the cooling is very slow, the process is quite complete. Also, according to Mr. Stead, phosphorus furnishes the same phenomenon, and if both are present the carbide collects round the phosphorus, as was the case in the nodules.

On the other hand, MM. Le Chatelier and Ziegler have shown that iron sulphide possesses the curious property of passing with great ease through the intercrystalline fissures, whatever be their nature, which occur in a mass of iron. The Canon Diablo meteorite certainly contains many fissures, and it is in these fissures, filled with carbon, that the diamonds are found. Thus it seems as though at a later period the sulphur had reacted upon the carbide and phosphide. Finally, we must add that if sulphur, phosphorus, and silicon tend to displace carbon from iron, the addition of nickel to iron also diminishes the solubility of carbon in the alloy. These two phenomena have combined to separate out the carbon from what must have been a liquid solution when carbon silicide was formed.

Later we propose to study the influence of pressure on these various reactions.—*Comptes Rendus*, November 14, CXXXIX., No. 20.

SOME PHYSICAL CHARACTERS OF THE SODIUM BORATES, WITH A NEW AND RAPID METHOD FOR THE DETERMINATION OF MELTING-POINTS.*

By CHARLES HUTCHENS BURGESS and ALFRED HOLT, jun.

(Concluded from p. 286).

WE have analysed a number of the glasses and crystals obtained with various mixtures, and obtained most unexpected and interesting results.

The analysis of a borate is always a matter of difficulty, but we found the following method worked quite well and gave accurate results:—A weighed quantity of the substance (glass or crystals in very fine powder) was evaporated to dryness twice with fairly strong hydrochloric acid. By this means all the sodium was converted into the chloride. The dry powder thus obtained was repeatedly treated with small quantities of ethyl alcohol, and evaporated to dryness. By this means all traces of hydrochloric acid were removed, as well as the whole of the boric acid, so that pure sodium chloride remained. This was dissolved in water and estimated by titration with N/10 silver nitrate solution, using potassium chromate as indicator.

The complete separation of the crystals from the glass was by no means an easy matter. We found that quite the easiest and most satisfactory method was to crush up the substance into coarse powder, and then to pick out with forceps the really glassy fragments and the crystalline masses. This was quite easy by using a lens.

* A Paper communicated to the Royal Society, October 27, 1904.

Though the crystals and glass have different specific gravities, it was not found possible to obtain a real separation by means of a heavy liquid. This was because pieces of material which looked wholly crystalline often contained glass in the interior, so that they would float anywhere in the liquid.

We also tried extraction with hot methyl alcohol, which is a solvent for boric anhydride, for if the crystals had been due to a separation of a borate from its solution in boric anhydride, this should have left the compound pure. As a matter of fact, we found that the methyl alcohol decomposed both the crystals and glass, giving methyl borate, boric acid, and sodium methylate. Both glass and crystals were decomposed at the same rate.

Attempts to use water as a means of separation were also failures, since the solubility of both glass and crystals is about the same.

The results of our analyses are as follows:—

(i.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$.*—This mixture crystallised completely in a few hours, giving a hard white completely crystalline mass. When about two-thirds had crystallised the glass and crystals were separated, and gave on analysis:—

Glass = 30.9 per cent Na_2O ; crystals = 31.0 per cent Na_2O .

(ii.). *Mixture of Composition about $3\text{Na}_2\text{O} \cdot 8\text{B}_2\text{O}_3$.*—This crystallised completely, and had the same characters as (i.). On analysis obtained:—

Glass = 25.86 per cent Na_2O ; crystals = 25.81 per cent Na_2O .

(iii.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.*—This crystallised completely, and had the same characters as (i.). On analysis obtained:—

Glass = 18.70 per cent Na_2O ; crystals = 18.67 per cent Na_2O .

(iv.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$.*—This crystallised very nearly completely, but seemed to contain small translucent glass-like fragments. On analysis obtained:—

Glass = 11.5 per cent Na_2O ; crystals = 13.7 per cent Na_2O .

(v.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 8\text{B}_2\text{O}_3$.*—This did not crystallise completely. After very prolonged heating it nearly all changed to a crystalline mass with an almost waxy lustre, but which was not really wholly crystalline. There was always, in addition, a portion of the mass which remained a glass. On analysis obtained:—

Glass = 10.06 per cent Na_2O ; crystals = 11.90 per cent Na_2O .

(vi.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 12\text{B}_2\text{O}_3$.*—Only about half would crystallise, and this took a very long time. On analysis obtained:—

Glass = 2.1 per cent Na_2O ; crystals = 12.2 per cent Na_2O .

(vii.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 16\text{B}_2\text{O}_3$.*—After heating this mixture for several days only a very small amount crystallised. On analysis obtained:—

Glass = 4.18 per cent Na_2O ; crystals = 10.02 per cent Na_2O .

(viii.). *Mixture of Composition about $\text{Na}_2\text{O} \cdot 40\text{B}_2\text{O}_3$.*—This could not be crystallised at all.

From these numbers it appears that, with mixtures between $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ and $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$, the crystals and glass have absolutely identical composition, but with mixtures containing more boric anhydride than $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ only a part (decreasing in quantity as the amount of boric anhydride present increases) crystallises, and this part has approximately the composition $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$.

As the crystals of the mixture of this composition contain more sodium than the glass, it seems probable that, could

one obtain the crystals really pure and not entangling any glass, the composition might approach that of $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.

The nearness in composition of the crystals obtained from mixtures varying from $\text{Na}_2\text{O} \cdot 16\text{B}_2\text{O}_3$ to $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$, makes it seem fairly certain that it is the same compound which separates out in all of them, and that the differences in the analyses are due to the crystals being mixed with more or less glass which it was impossible to remove. In experiment (vi.) the crystals and glass were particularly well separated, and the result is shown by the great difference in their analyses.

It seemed so curious that, with mixtures of composition $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$ to $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, the glass and crystals should give similar analytical results, that we thought it worth while to try fractional crystallisation of the glasses to see if we could detect any differences between the different crystalline portions.

The analyses of these various portions gave the following results:—

(i.). *For a Mixture of Composition about $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.*

		Per cent Na_2O
First portion	Glass	29.7
	Crystals	29.3
Second portion	Glass	29.9
	Crystals	29.2
Third portion	Glass	30.3
	Crystals	30.5
Fourth portion	Glass	30.2
	Crystals	30.1

(ii.). *For a Mixture of Composition about $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$.*

		Per cent Na_2O
First portion	Glass	18.7
	Crystals	18.6
Second portion	Glass	18.6
	Crystals	18.4

We also fractionally crystallised borax itself five times, when the final crystalline portion was found to contain 30.8 per cent Na_2O , theory for $\text{Na}_2\text{B}_4\text{O}_7$ requiring 30.7 per cent Na_2O .

These differences are negligible, and the crystals that separate out from the glass have exactly the same composition from the beginning.

These results show at once that this crystallisation is not due to the separation of any single compound, as we had previously supposed, but that it is more probably due to the formation of mixed crystals or a solid solution from a supersaturated liquid.

All the various crystalline fractions obtained from any one glass of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ to $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3$ were found to melt at identical temperatures, as also did the residual glasses. Further, the crystalline portions, when melted, gave glasses which had a melting-point identical with that of the previous residual glass, and these residual glasses could, in their turn, be changed to crystals with similar melting-points to those which had originally been separated.

This shows most conclusively the identity of the crystals and glass in chemical composition. We have also determined in the case of several mixtures the temperatures at which this crystallisation takes place. The curve indicating these temperatures is shown in Fig. 2 by the line joining A A.

A bead of the glass was put on the platinum wire of our melting-point apparatus, and the temperature raised extremely slowly, whilst the bead was watched with a lens. In the case of those mixtures which melted before the change occurred, no weight was attached to the bead. The crystallisation appeared to start at a fairly well defined temperature, and, if it was maintained, would gradually spread through the bead.

It is a little hard to say exactly what is the meaning of this curve A A (Fig. 2), and all that seems certain is that it

gives approximately the temperatures at which the rate of crystallisation assumes a sufficient velocity to visibly change the state of the substance.

From a consideration of the melting-point curves, together with the analytical and other observations we have described, it is possible to form some idea as to the nature of these glasses and the crystals into which they are wholly or partially transformable.

The glass must be regarded as a superfused—and, therefore, meta-stable—form of the crystals, behaving in several respects as if it were a liquid of enormous viscosity.

Now, on considering the behaviour of the glasses ranging in composition from pure boric anhydride to $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$, it will be noticed that the supposition of the existence of a borate of about the composition $\text{Na}_2\text{O} \cdot 5\text{B}_2\text{O}_3$, which is dissolved in boric anhydride, will explain the observed facts. A mixture of composition $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ cannot be crystallised at all, and one of composition $\text{Na}_2\text{O} \cdot 16\text{B}_2\text{O}_3$ only partially crystallises; hence some point between these mixtures will give the maximum solubility of this borate in boric anhydride. On further increasing the amount of this borate present, the glass becomes a supersaturated and superfused liquid, the amount of crystallisation measuring the supersaturation.

Somewhere between $\text{Na}_2\text{O} \cdot 6\text{B}_2\text{O}_3$ and $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ no free boric anhydride remains in the solution, and the whole mass will crystallise for the first time.

On further addition of sodium, another borate of composition near $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$ begins to be formed, and we have shown that in any mixture between these two compounds both crystals and glass have identical compositions. We are here probably dealing with a case of solid solution, and the glass is merely its superfused form.

The character of the curve would indicate that there are two types of crystals: one rich in B_2O_3 , the other rich in Na_2O , and the lowest point of the curve is the eutectic-point formed by mixtures of these two.

That the crest of the curve does not occur with the composition $\text{Na}_2\text{O} \cdot \text{B}_2\text{O}_3$ can be most conveniently explained by the fact that solid solutions cannot be treated as pure substances, and so a slight shifting of the maximum point is to be expected. The further depression of the melting-point curve probably indicates the eutectic-point between these crystals, rich in Na_2O , and sodium carbonate.

In conclusion, we wish to express our thanks to Professor H. B. Dixon and Mr. D. L. Chapman for the kindly interest they have taken in our work.

NOTE.—In the woodcuts illustrating this article (p. 285) Fig. 1 was accidentally inserted upside down.

(a) The Preparation of Sodium Amide.

Sodium amide was discovered about the year 1808 by Gay-Lussac and Thenard during an investigation of the properties and reactions of the then newly discovered metals, potassium and sodium ("Recherches Physico-chimiques," i., 337). Fifty years later it was subjected to further scrutiny by Beilstein and Geuther (*Liebigs Ann. Chem.*, 1858, cviii., 88). In 1892, W. Wislicenus first used it as a source of hydronitric acid, as stated above (*Ber.*, 1892, xxv., 2084). And finally, in 1894, Titherley prepared it in large quantities, and carefully studied its composition and many of its properties (*Journ. Chem. Soc.*, 1894, lxx., 504; lxxi., 460).

In the work here to be described, attention has been paid to the following considerations involved in the preparation of the compound:—(1) The action of molten sodium upon vessels of different materials; (2) construction of safe and convenient apparatus for enclosing the vessel containing the molten sodium; (3) necessary precautions to be employed in obtaining ammonia and sodium of sufficient purity; (4) means of securing good contact between the reacting substances; (5) the influence of temperature upon the nature of the product; and (6) method of analysing the product. These points will be considered in detail.

(1) The durability of vessels of different materials was tested in the course of several preliminary experiments, in which were used a porcelain boat, a platinum boat, a tube of hard, thick glass, a silver crucible and a nickel crucible. In each case several grms. of sodium were heated in the vessel under examination to a temperature of from 250° to 300°, in a current of ammonia, for about four hours. It was found that the interior of the porcelain boat had completely lost its glaze, and had assumed a dark brown colour, presumably due to the presence of free silicon liberated by the action of the sodium. The action upon the platinum boat was so marked that the amide obtained left, on treatment with water, a soft, spongy mass of platinum which retained the shape of the original product, and showed, under the microscope, a peculiar foliated structure. The glass tube stood the test surprisingly well. The surface, where it had come into direct contact with the molten sodium, was clouded to some extent, but the walls had not been eaten away appreciably. The silver crucible was acted upon to such an extent that the product firmly adhered to it on solidification, and showed a residue of numerous little spangles of silver when treated with water. When the sodium amide was prepared in a nickel crucible, however, the metal suffered no appreciable injury. The amide, after it had cooled, was easily removable by tapping the crucible and gently pressing its sides.

These results are not entirely in accord with those obtained by Titherley, who concluded that "platinum is only slowly corroded, but after a few weeks' constant use the metal becomes friable and much corroded" (*Journ. Chem. Soc.*, 1894, lxx., 504). In his later experiments he used a silver boat, saying that "the amide is practically without action on the metal." For preparing the amide on a large scale he suggests the use of a polished iron retort. This material, however, is open to serious objection. In the early experiments in this laboratory, dating back as far as 1895, a polished iron crucible was used in the preparation of the sodium amide, and the amide was then heated in a current of nitrous oxide in a second iron crucible to convert it into the trinitride. On dissolving the product of the second reaction in water and acidifying the solution with sulphuric acid, a heavy blue precipitate resulted. This was found to be essentially Prussian blue. On distilling off the hydronitric acid from this acidified solution the distillate was found to contain hydrocyanic acid as well. It was at first suspected that the carbon necessary to the formation of this hydrocyanic acid came from the kerosene in which the metallic sodium had been kept. To avoid the presence of this element, large pieces of sodium 9 inches long by 3 inches in diameter were procured, and after fully half an inch of the end had been cut off a core of sodium,

HYDRONITRIC ACID AND THE INORGANIC TRINITRIDES.*

By L. M. DENNIS and A. W. BROWNE.

(Continued from p. 288).

II.—EXPERIMENTAL.

A.—A Study of the Wislicenus' Method for Preparing Hydronitric Acid.

The hydronitric acid used in this investigation, as well as in the earlier ones carried on in this laboratory, has been made entirely by the Wislicenus method, and several years ago a careful examination of this process was begun with a view to ascertaining the conditions most favourable to a high percentage yield, especially when the sodium amide and sodium trinitride were prepared on a somewhat large scale. In describing our results, it may be well to classify the experiments under—(a) The Preparation of Sodium Amide; (b) The Preparation of Sodium Trinitride from Sodium Amide; and (c) The Preparation of Hydronitric Acid from Sodium Trinitride.

* From the *Journal of the American Chemical Society*, xxvi., No. 6, 1 *Ber.*, 1892, xxv., 2084.

not over 1.5 inches in diameter, was cut from the middle of the stick. The use of this material in the preparation of fresh samples of sodium amide in iron crucibles diminished the amounts of hydrocyanic acid and cyanides that were formed, but did not lead to the total avoidance of these products. It was then suspected that the carbide of iron present in the iron of the crucible might be attacked by the molten sodium and furnish the cyanogen. To test this supposition, fresh portions of the amide were prepared in crucibles made of nickel that was free from carbon, and no indication of the formation of either Prussian blue or hydrocyanic acid was obtained upon examination of the products. This formation of hydrocyanic acid, when iron vessels were used, has been pointed out by Szarvasy (*Journ. Chem. Soc.*, 1900, lxxvii., 603), who did not attempt to avoid the formation of cyanides, but separated the sodium cyanide from the sodium trinitride by treating the mixture with alcohol, the sodium cyanide remaining in solution. In all of the later work in this laboratory the sodium amide and the sodium trinitride have been prepared in nickel dishes 5 inches in diameter with perpendicular sides 3 inches high. As a result of long-continued use these dishes show signs of being somewhat attacked by the sodium, but the polishing of the dish with fine sea-sand before each run prevents any perceptible action upon it during the course of a single experiment.

FIG. 1.

(2) In the above examination of the action of sodium on the material of the container the porcelain and platinum boats were heated in combustion tubing, the small silver and nickel crucibles in vertical glass tubes 2.5 inches in diameter and sealed at one end, while the large crucibles were heated in a perpendicular iron tube 3.5 inches in diameter and closed at each end with a heavy screw cap, the upper cap being perforated for the entrance and exit of the gases. For preparing the sodium amide in large amounts in the 5-inch nickel dishes above mentioned a special container was necessary, and after many experiments with different devices the apparatus shown in Fig. 1 was finally adopted.

The can A is of sheet iron and is provided with a double bottom and with a grooved top, κ, κ' , into which fits the cover B. This has three tubular openings, H, H', for rubber stoppers holding respectively the inlet tube for ammonia D, the outlet tube E, and the thermometer F. The nickel dish G stands upon a little tripod which

prevents direct contact between the dish and the highly heated bottom. No solder was used in making the can. All joints were fastened with rivets. After the cover has been placed in the grooved top, the outside annular space is tightly packed with asbestos and sand. The can is placed upon a thick iron plate, and heated with a triple burner.

(3) The ammonia used in several of the earlier experiments was prepared from ammonium chloride purified according to the method of Stas (*Untersuchungen über die Gesetze der chemischen Proportionen*, German translation by Aronstein, p. 49). A saturated solution of the ordinary "C. P." salt was boiled with one-tenth its volume of concentrated nitric acid until chlorine was no longer evolved. The crystals that separated on cooling were re-dissolved, and similarly evaporated with a smaller amount of acid. The crystals thus obtained were dried and mixed with twice their weight of calcium hydroxide. The mixture was then placed in a seamless copper bottle, was moistened with a little water, and was heated. By this means freedom from pyridine bases was insured. Comparative tests, however, in which other conditions were kept constant showed this extreme precaution to be unnecessary, and consequently ordinary "C. P." ammonium chloride was commonly employed. The ammonia was dried by passing it through a long chain of tubes containing fused sodium hydroxide and soda-lime. It was not found necessary to use a tube containing metallic sodium, as suggested by Titherley.

The sodium used in the experiments was cut from the centre of large sticks of the metal for the reason already mentioned. In handling the sodium, care was taken to warm all apparatus with which it was to be brought into contact, in order to drive off the film of moisture that is present at ordinary temperatures.

(4) To test the effect of greatly increasing the surface of contact between the reacting substances, two simultaneous experiments were conducted at the same temperature (about 250°). In one the ammonia was allowed to pass, as usual, over the surface of the molten sodium, while in the other it was led beneath the surface of the molten sodium through a hard glass tube. The results of the analysis of the products obtained by these two different treatments are given in Table I.

TABLE I.

Time of action Hours.	Per cent nitrogen.		Per cent sodium.	
	Found.	Theory.	Found.	Theory.
Surface contact only $4\frac{1}{2}$	31.0		61.2	
		35.9		59.0
Ammonia bubbling through the molten sodium 1	35.3		59.4	

These results show that when the ammonia passes through the molten sodium rather than over its surface, the formation of the amide is much accelerated—one hour's treatment by the bubbling process yielding a product of greater purity than four and one-half hour's treatment by surface contact. At the beginning of the experiment, after the sodium has become molten, the tube is submerged until it almost reaches the bottom of the dish. Then, from time to time, as the action proceeds, the tube is slightly raised, to avoid unnecessarily stirring up the amide, which sinks to the bottom as it is formed. Finally, when only a small globule of the metal remains, the tube is raised out of the liquid during the remainder of the treatment. No very perceptible error seems to be introduced by the slight action of the sodium upon the hard glass tube through which the ammonia is led. A tube of pure nickel, however, would undoubtedly be preferable to one of glass.

(5) The rapidity of action of the ammonia upon the molten sodium was found to increase with the temperature, as was to be expected. But at temperatures much above

350° (which was the temperature found on the whole to give the best practical results) there seemed to be some loss of the product by sublimation. This was noted also by Titherley, who worked chiefly between temperatures of 300° and 400°. At temperatures below 250°, on the other hand, rather curious results were obtained in our work. Although in every case the reaction seemed to have been completed, analysis invariably showed too low a percentage of nitrogen, and too high a percentage of sodium. Moreover, the deficit of nitrogen and excess of sodium showed a tendency to increase as the temperature became lower. At first this was attributed to the possible presence of uncombined sodium dissolved in the amide; but when pieces of the product were thrown upon water beneath an inverted glass tube filled with water, no hydrogen was liberated.

In Table II. are given the results of three experiments conducted at different temperatures in the neighbourhood of the temperature limit below which apparently a good product cannot be obtained. In the second and third of these experiments, about 100 grms. of sodium were employed in each case, while in the first a somewhat smaller amount was used. The method of bubbling was used in each case, and the reaction was allowed to proceed to completion.

TABLE II.

Per cent of—	Theory for NaNH ₂ .	No. 1. (250°)	No. 2. (240°)	No. 3. (200°)
Sodium	59.0	59.4	61.4	71.2
Nitrogen	35.9	35.3	33.6	23.4

It would appear from the foregoing results that at a temperature below 250° a satisfactory product is not obtained.

(6) Method of analysing the amide. Beilstein and Geuther (*Liebigs Ann. Chem.*, 1858, cviii., 88) made analyses of the compound by dissolving weighed samples in dilute hydrochloric acid in a long-necked flask, evaporating the solution to dryness, and determining the ratio between the amounts of sodium chloride and ammonium chloride formed.

Titherley (*Journ. Chem. Soc.*, 1894, lxxv., 504) in one series of experiments attempted to determine the yield of sodium amide by ascertaining the ratio between the weight of sodium taken and that of the product formed. In his second series he obtained the ratio between the increase in weight due to the change of sodium into amide and the weight of hydrogen evolved. In his experiments very satisfactory results were obtained by the use of this method, because, no doubt, of the extreme precautions he had taken to exclude air and moisture from the apparatus. For general use, however, the method used in his first series, at least, is open to the objection that it would fail to show even a considerable error due to the action of air or moisture upon the sodium, for the reason that the molecular weights of NaNH₂, NaO (= $\frac{1}{2}$ Na₂O₂) and NaOH are nearly the same.

It is evident that definite information concerning the yield of sodium amide can be obtained only by determining the percentages of both nitrogen and sodium in the product. To accomplish this a weighed portion of the product was placed in a Kjeldahl flask provided with a Reitmeier bulb and a dropping funnel. Water was introduced through the dropping funnel, and the ammonia set free by the decomposition of the sodium amide was distilled off into standard hydrochloric acid, the excess of acid being then determined by titrating back with standard sodium hydroxide, using methyl orange as the indicator. To ensure complete removal of the ammonia, the solution in the Kjeldahl flask was carefully evaporated to dryness, re-dissolved in fresh water and again evaporated to dryness. The percentage of sodium was determined by titrating the residue of sodium hydroxide in the flask with standard hydrochloric acid. This method was used in obtaining the results given in Tables I. and II.

(To be continued).

THE NOBEL PRIZES.

THE Nobel Prize for Physics has been awarded to Lord Rayleigh, Professor of Natural Philosophy at the Royal Institution. The Chemistry Prize is conferred upon Sir William Ramsay, Professor of Chemistry at University College.

The distribution of the Nobel Prizes took place in the Great Hall of the Academy of Music at Stockholm on the 10th inst., in the presence of King Oscar. Lord Rayleigh and Professor Ramsay received their Prizes, together with Diplomas and Gold Medals, in person from his Majesty. The sum of money attaching to each Prize amounts to 140,858 kroner (about £7825).

Lord Rayleigh proposes to present to Cambridge University the value of the Nobel Prize for Physics which has just been awarded to him.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.

Ordinary Meeting, Thursday, December 1st, 1904.

Prof. W. A. TILDEN, D.Sc., F.R.S., President, in the Chair.

MESSRS. A. D. COWPER and E. S. SIMPSON were formally admitted Fellows of the Society.

Certificates were read for the first time in favour of Messrs. Andrea Angel, M.A., 41, Wellington Square, Oxford; James H. Campbell, 3, Morrison Terrace, North Road, Bellshill, N.B.; Bernard Collett, 79, Eastbourne Terrace, Gainsborough; Herbert Goodier, 16, Hall Road, Shipley; George Moss Lloyd, M.A., M.Sc., Queen's Road, Rock Ferry; Thomas Pennycuik, B.Sc., 6, Lorne Street, Fairfield, Liverpool; Bert Perrott, Ael-y-Bryn, Penywn Road, Neath, Glam.; William Henry Ratcliffe, B.Sc., 18, Wheeler Street, Maidstone; Frederick George Richards, 21, Dutton Street, Manchester; Harold Rudolph Rogers, B.A., 75, South Side, Clapham Common, S.W.

The PRESIDENT drew attention to the stand for the display of certificates of candidates for election which had been placed in the Library, and stated that, as the certificates are now printed in full in the *Proceedings*, they would not in future be brought down from the Library on the occasion of the ballot.

A ballot for the election of Fellows was held, and the following were subsequently declared duly elected:—William Harold Richard Allen; Walter Henry Bentley, B.A.; John Wycliff Black; Thomas Story Busher, B.A.; Lawrence Caldecott; Robert John Caldwell, B.Sc.; Peter Skinner Clark, M.B., Ch.M.; Frederick Clarkson-Harold; Jabez Horace Cooper, B.A.; William Crabb, B.Sc.; James Edward Cunningham; William Herbert Dalton; Harold Deane, B.Sc.; Francis Dickinson; Edward Evans; John Evans; Thomas Wallace Fagan, B.A.; John Kerr Forrest; Archie Willoughby Henszell; Thomas Reginald Hodgson; George William Thomas Horrod; John Kenneth Harold Inglis, M.A., B.Sc.; Thomas Campbell James, B.A., B.Sc.; Walter Richmond James; John Richard Johnson; Horace Francis Jones; William App Jones, Ph.D., A.M.; Alfred Francis Joseph; Gustav Komppa, Ph.D.; James Stanley Lauder; Arthur Garfield Levy, B.Sc.; James Patrick Longstaff, B.Sc.; Arthur Thomas McDougall, B.A.; Harold Joseph Clarke Mathews; Ernest Westby Millar; George Frederick Phillips, B.Sc.; Marie Jean Louis Ernest Rouillard, B.Sc.; Percy Edwin Spielmann; Harry Stanley, B.Sc.; Thomas Sutcliffe; Paul John Thibault; Arnold Bertram Tonkin; Douglas Frank Twiss, M.Sc.; Edwin Roy Watson, B.A., B.Sc.; Herbert Wood Watson, B.Sc.; Henry Bridges Weeks; William Henry Willcox, M.D., B.Sc.; Frank John Wyeth, M.A.

Of the following papers, those marked * were read :—

*201. "The Nitrides of the Alkali Metals and Metals of the Alkaline Earths and their Decomposition by Heat." By PRAFULLA CHANDRA RAY.

Solutions of the nitrides of barium and calcium, like those of the alkali metals, can be safely evaporated to dryness at the boiling temperature without decomposition or oxidation taking place.

A solution of magnesium nitride prepared by the double decomposition between barium nitride and magnesium sulphate is perfectly stable at the ordinary temperature, but it cannot be concentrated on the water-bath, as it undergoes decomposition even at 60°, evolving nitric oxide. The solution, when concentrated under reduced pressure over sulphuric acid, yields the hydrated salt $Mg(NO_2)_2 \cdot 3H_2O$, which, when kept in a desiccator, loses only one molecule of water, the dehydration not going any further. All the nitrides described have a faint yellow colour. When barium nitride is heated under reduced pressure at 225–300°, the following reactions occur :—

whereas at temperatures between 300° and 500° or upwards the following change takes place :—

The other nitrides behave similarly. In the earlier stages, the gaseous products of decomposition are mainly nitric oxide and nitrogen, in the second they are chiefly nitrogen peroxide and oxygen. It is difficult to distinguish sharply between these two stages, and an intermediate phase has been observed, $Ba(NO_2)_2 = Ba(NO_3)_2 + O_2$. The decomposition of magnesium nitride begins at 60°, and at 120° that of the first stage is complete, resulting in the formation of a basic nitrate, $Mg(NO_3)_2 \cdot MgO$, which is stable even at 175°.

*202. "The Metallic Derivatives of Nitrogen Iodide and their Bearing on its Constitution." By OSTWALD SILBERRAD.

On examining Guyard's copper derivative (compare *Comptes Rendus*, 1884, xcvi., 526) the compound was found to be a cuprosamine periodide, $Cu_2I_2(5NH_4)_2I_2 \cdot H_2O$, and not a derivative of nitrogen iodide; it is not explosive, and has the properties of a periodide. On heating, it evolves iodine vapour, and by treating with potassium iodide solution the loosely combined iodine is removed quantitatively. The regeneration of nitrogen iodide from the cuprosamine periodide by ammonia must also be regarded as distinct evidence of its periodide character, for, according to this view, the loosely combined iodine reacts with ammonia precisely as does potassium periodide.

Cuprosamine Iodide, $Cu_2I_2 \cdot NH_3 \cdot H_2O$.—When the foregoing periodide is treated with potassium iodide solution, the loosely combined iodine is removed and a green crystalline residue remains behind, which dries to an olive-green crystalline powder having the above formula; it is insoluble in water, but dissolves fairly readily in ammonia.

The silver derivative formulated by Szuhay as AgN_3 (Ber., 1893, xxvi., 1933) was again investigated, but it was found that by following his method a compound of constant composition could not be prepared. By the addition of iodine chloride solution to an ammoniacal silver solution, a pure product having the formula N_3NH_2Ag was obtained. The substance decomposes readily, even at the ordinary temperature and especially when exposed to light; in the dry state, it explodes on the slightest friction. It dissolves readily in potassium cyanide, and is regenerated by the addition of ammoniacal silver nitrate. Szuhay stated that an intermediate potassium salt was formed. This is disproved by an examination of the solution obtained by adding potassium cyanide to nitrogen iodide. Exactly 3 mols. of potassium cyanide were required to dissolve 1 mol. of nitrogen iodide, this number being independent of the excess of ammonia present. The pro-

ducts identified were cyanogen iodide, potassium iodide, potassium carbonate, potassium cyanate, ammonia, and cyanogen. The mechanism of the change is as follows :—

At low temperatures and in concentrated solution the cyanogen iodide is partially precipitated, but at the ordinary temperature it readily decomposes in solution.

The action of potassium cyanide on the silver derivative took place in accordance with the equation :—

It was also found that although cyanogen iodide produced no precipitate of nitrogen iodide when added to ammonia, yet in the presence of silver the compound $N_3 : NH_2 \cdot Ag$ was readily obtained. The behaviour of the silver compound towards potassium cyanide is thus fully explained without any necessity for assuming the existence of an intermediate potassium salt.

*203. "Synthesis of 1:1-Dimethylhexahydrobenzene." By ARTHUR WILLIAM CROSSLEY and NORA RENOUF.

5-Chloro-3-keto-1:1-dimethyl-4-tetrahydrobenzene (Trans., 1903, lxxxiii., 117), when treated with sodium in moist etheral solution, yields 3-hydroxy-1:1-dimethyl-hexahydrobenzene, —

together with other substances not yet investigated. The product is a clear colourless liquid boiling at 99.5°/35 m.m., and having a marked odour of peppermint. When treated with fuming hydrobromic acid, it is converted into 3-bromo-1:1-dimethylhexahydrobenzene, a colourless liquid boiling at 98°/50 m.m. The bromine atom in this compound is readily replaced by hydrogen on heating with zinc dust in aqueous alcoholic solution, giving rise to 1:1-dimethylhexahydrobenzene, which is a colourless refractive liquid boiling at 117°/743 m.m., and having a geranium-like odour.

In 1902, Zelinsky (*Annalen*, 1902, cccxix., 318) described the preparation of dihydroisolarolene, which hydrocarbon, he suggested, was 1:1-dimethylhexahydrobenzene, and the authors are at present comparing the properties of these two hydrocarbons, and also the properties of 1:1-dimethyl-tetrahydrobenzene, with the hydrocarbons of the formula C_8H_{14} , which have at various times been obtained from derivatives of camphor.

*204. "The Formation and Reactions of Imino-compounds. I. Condensation of Ethyl Cyanoacetate with its Sodium Derivative." By HAROLD BARON, FREDERICK GEORGE PERCY REMFRY, and JOCELYN FIELD THORPE.

Ethyl cyanoacetate condenses with its sodium derivative, forming the sodium compound of ethyl α -cyano- β -imino-glutarate, $CO_2Et \cdot CHNa \cdot C(NH) \cdot CH(CN) \cdot CO_2Et$, which can readily be converted into ethyl α -cyano- β -imino-glutarate, $CO_2Et \cdot CH_2 \cdot C(NH) \cdot CH(CN) \cdot CO_2Et$. This substance contains three hydrogen atoms capable of replacement by sodium in the order indicated by the numerals.

Ethyl α -cyano- β -imino-glutarate and its alkyl derivatives yield the corresponding ethyl hydrogen salts, $CO_2H \cdot CHR \cdot C(NH) \cdot CR(CN) \cdot CO_2Et$, on hydrolysis with sodium carbonate.

These compounds, on heating above their melting points, are converted into derivatives of glutazine, which can be transformed into the corresponding derivatives of 2:4:6-trioxypyridine by suitable reagents.

The same glutazine derivatives are formed by the action of concentrated sulphuric acid on the diethyl salts.

The substitution derivatives of glutazine can react in the two forms :—

The mono-substitution derivatives react in the second form towards acid hydrolysing agents, and in the first form towards nitrous acid.

The di-substitution derivatives react only in the second form, whilst the tri-substitution derivatives react in the first form.

Ethyl α -cyano- β -iminoglutarate,—

can be converted into a derivative of glutazine in two ways. Thus, with concentrated sulphuric acid, it yields ethyl glutazincarboxylate,—

but with sodium carbonate solution it is converted into glutazine cyanide,—

*205. "The Affinity Constants of Aniline and its Derivatives." By ROBERT CROSBIE FARMER and FREDERICK JOHN WARTH.

The affinity constants of aniline and its derivatives are best determined through the hydrolytic dissociation of their salts. For this purpose, the method of distribution between two solvents, previously employed by one of the authors (Farmer, *Trans.*, 1901, lxxix., 863), has been applied to these compounds. The advantages of the method are, mainly, its applicability to (1) sparingly soluble organic compounds, (2) strongly coloured solutions, (3) solutions in which a slight decomposition interferes with titrations, (4) salts which are hydrolysed to the extent of nearly 100 per cent in solution.

Comparative experiments showed that the sulphates of aniline and the toluidines were in all instances hydrolysed to a greater extent than the corresponding hydrochlorides, but the relative difference decreased in dilute solution.

o-Nitroaniline showed practically no tendency to form a hydrochloride in aqueous solution, and *p*-nitroaniline was a much weaker base than the meta-isomeride. The nitroanilines exhibited no acidic properties when examined by the same method in presence of caustic potash.

The substituents arranged themselves in the following order as regards their influence on the affinity constant of aniline, the nitro-group being the most electronegative: NO_2 , CO_2H , $\text{N:N-C}_6\text{H}_5$, Br , Cl , CH_3 , OCH_3 . α - and β -Naphthylamines were somewhat weaker bases than aniline. Acetanilide and aceto-*o*-toluidide showed practically no basic properties. *p*-Nitrosomethylaniline possessed easily measurable acidic properties in addition to its basic properties, but *p*-nitrosodimethylaniline showed no tendency to form salts with alkalis.

206. "The Attractive Force of Crystals for like Molecules in Saturated Solutions." By EDWARD SONSTADT.

The author describes the preparation of saturated solutions in pairs or in sets, in which to one or more of the solutions is added a quantity of the crystals of the dissolved salt, the flasks or other containing vessels being left together in a cellar in which the temperature varies only slowly. The added crystals draw from the solution in which they are deposited a certain portion of the salt, so that the supernatant liquid contains, after a time, an appreciably smaller proportion of the dissolved salt than the solutions contained in the other vessels, to which no crystals had been added. The determinations were made either by evaporating a weighed portion of each of the solutions, and weighing the residue, or by taking the density of the solutions by a specific gravity bottle.

207. "The Grignard Reaction applied to the Esters of Hydroxy-Acids." By PERCY FARADAY FRANKLAND and DOUGLAS FRANK TWISS.

By acting on dimethyl tartrate with magnesium phenyl bromide and treating the product with dilute sulphuric acid, the authors have obtained a compound crystallising in small, white needles (m. p. 148°), which is presumably *aa\delta\delta*-tetraphenylerythritol, $(\text{C}_6\text{H}_5)_2\text{C}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{OH}) \cdot \text{C}(\text{OH})(\text{C}_6\text{H}_5)_2$. It is powerfully dextrorotatory, a 4.327 per cent solution in ethyl alcohol giving $[\alpha]_D^{20} + 182.8^\circ$. The compound is isomeric with the already known benzoinsipinacone (tetraphenylerythritol, m. p. 235°).—

$\text{C}_6\text{H}_5 \text{CH}(\text{OH}) \cdot \text{C}(\text{OH})(\text{C}_6\text{H}_5) \cdot \text{C}(\text{OH})(\text{C}_6\text{H}_5) \cdot \text{CH}(\text{OH}) \cdot \text{C}_6\text{H}_5$ obtained by Kauffmann (*Chem. Centr.*, 1898, i., 1232) by the electrolytic reduction of benzil or benzoins, and which is, of course, inactive.

The authors, who are proceeding with the investigation, are making this preliminary communication in consequence of the incidental description by Acree (*Ber.*, 1904, xxxvii., 2753) of the action of magnesium phenyl bromide on inactive methyl mandelate with production of triphenylglycol.

208. "Note on the Addition of Hydrogen Cyanide to Unsaturated Compounds." By ARTHUR LAPWORTH.

Knoevenagel has recently stated (*Ber.*, 1904, xxxvii., 4065) that mesityl oxide unites nearly quantitatively with pure hydrogen cyanide, and in proof he cites the yield of mesitylic acid obtained by adding potassium hydroxide to the mixture after eight days and then boiling. As potassium cyanide, in presence of potassium hydroxide, rapidly converts mesityl oxide into mesitylic acid, Knoevenagel's experiment throws no light on the subject.

Experiments at 100° with hydrogen cyanide dissolved in alcohol are apt to be misleading, as after some hours at this temperature the solution is often faintly alkaline, and is much more reactive than before heating. The author has never obtained an appreciable amount of additive product when hydrocyanic acid free from all trace of basic impurity was warmed with an $\alpha\beta$ -unsaturated ketone; nevertheless, the views which he has put forward as to the mechanism of such processes are altogether opposed to the assumption that pure hydrogen cyanide is devoid of additive properties in any instance where addition occurs in presence of a base or a metallic cyanide (compare Knoevenagel, *loc. cit.*, p. 4067).

Alkylidenecyanoacetic acids react very readily with hydrogen cyanide in presence of bases or metallic cyanides; the products vary with the precise conditions imposed, but with care it is easy to obtain nearly quantitative yields of compounds derived from the type $\text{CHX}(\text{CN}) \cdot \text{CH}(\text{CN}) \cdot \text{CO}_2\text{H}$, and from which alkylsuccinic acids are produced by acid hydrolysis. For example, phenylsuccinic acid may readily be synthesised from benzaldehyde, potassium chloroacetate, and potassium cyanide. The study of this reaction as applied to both fatty and aromatic aldehydes is in progress. Alkylidenemalononic acids do not appear to be capable of uniting with hydrogen cyanide.

Wislicenus Memorial Lecture.

The Wislicenus Memorial Lecture will be delivered by Professor W. H. Perkin, F.R.S., on Wednesday, January 25th, at 8.30 p.m.

THE ROYAL SOCIETY.

Anniversary Meeting, November 30th, 1904.

THE Copley Medal was awarded to Sir WILLIAM CROOKES, D.Sc., F.R.S.; the Rumford Medal to Prof. ERNEST RUTHERFORD, F.R.S.; the Davy Medal to Prof. W. H. PERKIN, F.R.S.; and the Hughes Medal to Sir JOSEPH WILSON SWAN.

In presenting the Copley Medal the President, Sir WILLIAM HUGGINS, said:—

The Copley Medal is awarded to Sir William Crookes, F.R.S., for his experimental researches in chemistry and physics, extending over more than fifty years. Ever since his discovery of the element thallium in the early days of spectrum analysis, he has been in the front rank as regards the refined application of that weapon of research in chemical investigation. Later, the discrepancies which he found in an attempt to improve weighings, by conducting the operation in high vacua, were tracked out by him to a repulsion arising from radiation, which was ultimately ascribed by theory to the action of the residual gas. This phenomenon, illustrated by the radiometer, opened up a new and fascinating chapter in the dynamical theory of rarefied gases, which the genius of Maxwell, O. Reynolds, and others, has left still incomplete. The improvements in vacua embodied in the Crookes tube led him to a detailed and brilliant experimental analysis of the phenomena of the electric discharge across exhausted spaces; in this, backed by the authority of Stokes, he adduced long ago powerful cumulative evidence that the now familiar cathode rays, previously described by C. F. Varley, must consist of projected streams of some kind of material substance. His simple but minutely careful experiments on the progress of the ultimate falling off in the viscosity of rarefied gases, from the predicted constant value of Maxwell, at very high exhaustions, gave, in Stokes's hands, an exact account of the trend of this theoretically interesting phenomenon, which had already been approached in the investigations of Kundt and Warburg, using Maxwell's original method of vibrating discs.

These examples, not to mention recent work with radium, convey an idea of the acute observation, experimental skill, and persistent effort, which have enabled Sir William Crookes to enrich physical science in many departments.

In presenting the Rumford Medal the President said:—

The Rumford Medal is awarded to Professor Ernest Rutherford, F.R.S., on account of his researches on the properties of radio-active matter, in particular for his capital discovery of the active gaseous emanations emitted by such matter, and his detailed investigation of their transformations. The idea of radiations producing ionisation of the type originally discovered by Röntgen, and the idea of electrified particles, like the cathode rays of vacuum tubes, projected from radio-active bodies, had gradually become familiar through the work of a succession of recent investigators, when Rutherford's announcement of a very active substance, diffusing like a gas with a definite atomic mass, emitted by compound of thorium, opened up yet another avenue of research with reference to these remarkable bodies. The precise interpretation of the new phenomena, so promptly perceived by Rutherford, was quickly verified, for radium and other substances, by various observers, and is now universally accepted. The modes of degradation, and the enormous concomitant radio-activity of these emanations, have been investigated mainly by Rutherford himself, with results embodied in his treatise on radio-activity and his recent Bakerian lecture on the same subject. It perhaps still remains a task for the future to verify or revise the details of these remarkable transformations of material substances, resulting apparently in the appearance of chemical elements not before present; but, however that may issue, by the detection and description of radio-active emanations and their transformations, Professor Rutherford has added an unexpected domain of transcendent theoretical interest to physical science.

In presenting the Davy Medal the President said:—

The Davy Medal is awarded to Prof. W. H. Perkin, jun., F.R.S., for his masterly and fruitful researches in the domain of synthetic organic chemistry, on which he has been continuously engaged during the past twenty-five years.

Dr. Perkin's name is identified with the great advances which have been made during the past quarter of a century

in our knowledge of the ring or cyclic compounds of carbon. Thus, in the year 1880, the cyclic carbon compounds known to chemists were chiefly restricted to the unsaturated groupings of six carbon atoms met with in benzene and its derivatives, whilst the number of compounds in which saturated carbon rings had been recognised was very limited, and it was indeed considered very doubtful whether compounds containing carbon rings with more or less than six atoms of carbon were capable of existence.

The starting point for Dr. Perkin's researches in this field of inquiry was his investigation of the behaviour of the di-halogen derivatives of various organic radicals with the sodium compounds of malonic, aceto-acetic, and benzoyl-acetic esters, which led to the synthesis of the cyclic polymethylene compounds up to those of hexamethylene, whilst heptamethylene derivatives were obtained by an adaptation of the well-known reduction of ketonic bodies leading to pinacones. The reactions thus introduced by Perkin are now classical, having proved themselves of the highest importance for synthetical purposes, and having been instrumental in stimulating the further investigation of the cyclic compounds of carbon.

Dr. Perkin also extended the same methods to the synthetical formation of carbon rings of the aromatic series, obtaining by means of ingeniously designed reactions derivatives of hydrindonaphthene and tetrahydronaphthalene.

But whilst the above achievements depend mainly on happily conceived and brilliantly executed extensions of the malonic and aceto-acetic ester synthesis, Perkin has, by a remarkable development of the Frankland and Duppa reaction for the synthesis of hydroxyacids, been successful in building up the important camphoric acid in such a manner as to place its constitution beyond doubt (1897).

Dr. Perkin has further devoted much attention to the important subject of the constitution of camphor, towards the elucidation of which he has contributed valuable experimental evidence embodied in a most important and elaborate paper, containing the results of many years' work in conjunction with numerous pupils, entitled "Sulphocamphylic Acid and Isolauronic Acid, with remarks on the Constitution of Camphor and Some of its Derivatives" (1898). Bearing on the same subject are later communications on camphoric acid and isocamphoric acid.

About the year 1900, Perkin, in prosecuting his researches on the constitution of camphor compounds, succeeded in devising synthetical methods for the production of what he has termed "bridged rings," of which a simple example is furnished by the hydrocarbon dicyclopentane

The universal admiration of organic chemists has been called forth by these investigations; they reveal, indeed, a wonderful capacity for devising reactions which coerce carbon atoms to fall into the desired groupings.

Of other publications displaying not only extraordinary experimental skill but close reasoning and the power of interpreting results, mention may be made of Dr. Perkin's memorable researches on the constitution of dehydracetic acid, berberine, brasilin, and hematoxylin respectively.

During the present year (1904), Dr. Perkin has made perhaps the most remarkable addition to the long list of his achievements by successfully synthesising terpin, inactive terpineol, and dipentene, substances which had previously engaged the attention of some of the greatest masters of organic chemistry.

In conclusion, it may be stated that Professor Perkin is not only the author of the above and numerous other important researches which are outside the scope of this brief summary, but that he has also created a school of research in organic chemistry, which stands in the very highest rank.

In presenting the Hughes Medal the President said:—

The Hughes Medal is awarded to Sir Joseph Wilson Swan, F.R.S., for his invention of the incandescent electric lamp, and his other inventions and improvements in the

practical applications of electricity. Not as directly included in the award, his inventions in dry-plate photography, which have so much increased our powers of experimental investigation.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 20, November 14, 1904.

The Employment of Helium as a Thermometric Substance, and its Diffusion through Silica.—Adrien Jaquerod and F. Louis Perrot.—It was proposed to use a helium thermometer to determine the melting-point of gold and the dilatation of some gases between 0° and 1000° . The gas, which was obtained from cleveite, was purified by passing it through copper oxide heated to dull redness and solid caustic potash. It was then mixed with about one-fourth of its own volume of oxygen and sparked for four or five hours. The excess of oxygen was absorbed by phosphorus. The gas, thus purified, gave only the characteristic lines of helium on spectroscopic examination; it was therefore quite pure. The gas was introduced into a thermometer with a silica bulb and heated. The temperature rose normally to the melting-point of gold, but the pressure of the gas, instead of rising regularly with the temperature, reached a maximum of about 900 m.m. and then began to fall. At 1100° it had fallen to atmospheric pressure, and went on falling regularly while the temperature remained constant. Its behaviour, therefore, was not due to leakage in the apparatus, but must be caused by diffusion of the gas through the silica. The rate of diffusion seems to be proportional to the pressure. Other experiments have shown that this diffusion takes place fairly rapidly at 510° , and is even perceptible at 220° .

Absorption of Hydrogen by Rhodium.—L. Quennessen.—Already inserted.

Action of Boric Acid upon Alkaline Peroxides and Formation of Perborates.—George F. Jaubert.—A mixture of crystallised boric acid and sodium peroxide was dissolved in cold water. After a short time white crystals separated out from this solution. Titration with KMnO_4 showed that these crystals contain 4.17 per cent of active oxygen, and their formula seems to be $\text{Na}_2\text{B}_2\text{O}_5 + 10\text{H}_2\text{O}$. By treating them with a mineral acid, a salt having the formula $\text{NaBO}_3 + 4\text{H}_2\text{O}$ was obtained. The latter does not decompose when kept dry, and since its solution in water yields hydrogen dioxide, it is a convenient reagent for the preparation of the latter.

Thioformic Acid.—V. Auger.—This acid was prepared in two ways:—1. By treating formic acid with NaPS_3 . It could not be obtained pure by this method. 2. From phenyl formate and sodium hydrogen sulphide, $\text{HCOOC}_6\text{H}_5 + \text{NaHS} = \text{C}_6\text{H}_5\text{OH} + \text{HCOSNa}$. The salt, precipitated by anhydrous ether, consists of long very deliquescent white needles. Its solution precipitates the salts of the heavy metals, giving unstable coloured salts.

Synthesis of $\beta\beta$ -Dimethyladipic Acid.—G. Blanc.— $\beta\beta$ -Dimethylglutaric anhydride, after being purified by crystallisation from petroleum ether, was reduced, and thus converted into the lactone, $\text{CH}_3 > \text{C} \begin{smallmatrix} \text{CH}_3 \\ \text{CH}_2 \end{smallmatrix} \text{CO} > \text{O}$. By heating this lactone to 275° with KCN, and by subsequent treatment, an acid having the formula $\text{CH}_3 > \text{C} \begin{smallmatrix} \text{CH}_3 \\ \text{CH}_2 \end{smallmatrix} \text{COOH}$ is obtained. This acid crystallises in little prisms which are very soluble in water, slightly soluble in benzene, and insoluble in petroleum ether. It melts at 87° . These properties show that it is identical with Tiemen's acid.

A New Sugar from Sorb Berries.—Gabriel Bertrand.—This sugar was first prepared in 1898 by Vincent and Meunier. They thought it contained 8 atoms of carbon. The author has shown that it is a hexavalent alcohol of formula $\text{C}_6\text{H}_{14}\text{O}_6$.

Berichte der Deutschen Chemischen Gesellschaft.
Vol. xxxviii., No. 15, 1904.

Varieties of Caoutchouc.—C. Harries.—The object of the author's research was to ascertain the connection between commercial caoutchouc and the juice as freshly obtained from the living tree. The fresh juice rapidly coagulates, and Weber has shown that ether extracts an oil from the latex which, on addition of traces of formic acid, polymerises to caoutchouc. Hence he supposes that the latex contains not caoutchouc as such, but a very easily polymerisable hydrocarbon, possibly an aliphatic diterpene, $\text{C}_{20}\text{H}_{32}$. The author obtained 300 c.c. of the juice of *Ficus magnol. Bori*, and treated it with ether on the spot, thus dissolving most of the constituents; a residue remained which contained a reducing sugar. The ether extract could be separated by filtration from the insoluble residue, which perhaps consists of albuminous substances. By the evaporation of the ether a yellow syrup was obtained from the extract; this partially crystallised on standing. By precipitation with alcohol it was shown that the extract consists of two substances:—(1) The substance which gives rise to caoutchouc, and (2) an oxygen compound, $\text{C}_{20}\text{H}_{46}\text{O}_3$. This latter crystallises well, and the greater part of it could be separated from the first by repeated treatment of the extract with a little ether. As the oxygen compound was thus removed it appeared that the other substance was not an oil, but a tough white elastic mass showing great resemblance to caoutchouc. It is perfectly soluble in a sufficient quantity of ether, but it could be shown that its properties are not those of a diterpene. On distillation it behaves exactly like caoutchouc. It may be precipitated directly from the latex by means of alcohol and purified by taking up with ether and precipitating with alcohol. Analysis shows that it has the composition of paracaoutchouc. If to the ethereal extract of the latex a drop of formic acid is added, a white coagulated mass separates at once. This product is soluble in ether, but loses its solubility gradually on drying or on repetition of the treatment. This gradual change of solubility (after isolation) is perhaps due to an increase in the molecule. Thus caoutchouc occurs in the latex of *Ficus magnol. Bori* (and also of *Ficus elastica*) in a form which differs in solubility from ordinary caoutchouc, but does not possess the properties of an aliphatic diterpene.

Separation and Isolation of Reducing Sugars by means of Hydrazine.—Emil Votocek and R. Vondracek.—Already noticed.

Antipodal Isomerism of Rhodose and Fucose.—Emil Votocek.—The author has proved his supposition that his rhodose and Tollens's fucose form an enantiomorphic pair, and has prepared from them the inactive sugar which is undoubtedly a true racemic body. This is the first case in which the stereoisomer of a natural sugar has been found in the free state. The fact that stereoisomeric sugars exist in nature is of great physiological interest; it shows, for instance, that the theory that nature only produces one of two enantiomorphic sugars is not universally correct. Thus the "directive force" which would cause the formation of only one series, e.g., the *d*-series, does not exist, though nature certainly produces this series far more commonly than the *l*-series.

Colloidal Silver Salts.—C. Paal and Franz Voss.—In continuing their researches on colloidal silver oxide the authors have found that if the silver salts of protalbinic or lysalbinic acid, which are formed when white of egg is subjected to alkaline hydrolysis, are dissolved in sodium carbonate solution, the excess of sodium carbonate removed by dialysis, and the liquid cautiously evaporated to

dryness, the sodium salt of the acid is formed and a colloidal silver carbonate. They have also prepared colloidal sulphide, chloride, bromide, and iodide of silver.

Microchemical Detection of Strontium and the Properties of Strontium Chromate.—W. Autenrieth.—On subjecting the salts of the metals of the alkaline earths to a microchemical examination the author has found that strontium chromate, when precipitated in neutral aqueous solution, very readily forms crystals. Barium chromate similarly prepared is amorphous or indistinctly crystalline, while calcium chromate is soluble in water. If one drop of a 10 per cent solution of potassium chromate is added to a 3 per cent solution of strontium nitrate, and the resulting crystals magnified 120 times, long yellow crystalline needles are seen, of length 100—200 μ and width 1 μ ; these collect together in clusters, and are very characteristic of strontium chromate. If the strontium solution is much weaker the crystals only separate out on standing for some time, and are then short thick hexagonal prisms. The author has not succeeded in getting spherical crystals as described by Behrens. The short thick crystals are also produced when a fairly dilute solution of strontium chromate in acetic acid or a mineral acid is allowed to stand for some hours after addition of excess of ammonia. Such a preparation on being kept for three months appeared to contain almost exclusively the crystals in the form of long needles. Thus strontium chromate possesses two crystalline modifications. The form which crystallises in thick prisms is probably the labile form, which appears to pass gradually into the stable modification crystallising in long needles. Strontium chromate when moist is easily soluble in acetic acid; when thoroughly dried at 120°, it is very slowly but completely dissolved. It is difficultly soluble even in boiling water. The easiest method of detecting barium, strontium, and calcium in presence of one another is to grind up the dry powdered chlorides repeatedly with absolute alcohol, and filter. Barium may then be detected in the insoluble portion by flame colouration, &c. The alcoholic filtrate is evaporated to dryness on the water-bath, the residue taken up with water, and filtered if necessary. Then a drop of potassium chromate is added to a drop of this solution, and examined under the microscope; the formation of characteristic long needles shows the presence of strontium. Calcium may be detected either spectroscopically or by means of the flame reaction, after evaporating the rest of the chloride solution with strong nitric acid, and separating the two nitrates by means of absolute alcohol.

Phosphorescing Zinc Sulphide.—W. P. Jorissen and W. E. Ringer.—The late De Visser has found that absolutely pure barium sulphide gives no trace of phosphorescence, while pure calcium sulphide only luminesces very feebly. By the addition of small quantities of bismuth powerful phosphorescence is produced, the maximum being reached when two atoms of bismuth are present in 100,000 atoms of barium or calcium; this effect is diminished by more as well as by less bismuth. De Visser states that in order that a sulphide may be capable of phosphorescing, it must contain in solid solution a compound of another metal which is in a state of electrolytic dissociation. The most refrangible radiations of the spectrum split up the ions of the foreign metal into a large number of electrons, which, by their vibration after illumination, cause phosphorescence. De Visser, whose experiments the authors are confirming and extending, examined many other metals, but discovered only a very few which could excite phosphorescence in the sulphides of calcium and barium. He thought it probable that many of these metals show invisible ultra-red or ultra-violet phosphorescence. He also found that the presence of some alkali salt in the sulphide was necessary for powerful phosphorescence, but no definite amount was required to cause maximum phosphorescence; he supposed that the alkali salt by fusing favoured the formation of the solid solution of bismuth in the calcium sulphide. Sidot's blende seems to behave in an exactly similar manner.

MISCELLANEOUS.

The Lavoisier Gold Medal has been awarded by the French Academy of Sciences to Professor Sir James Dewar, F.R.S., for his researches on the Liquefaction of Gases. This Medal was founded in 1900, to be given at such times as the French Academy should elect, in recognition of eminent services rendered to Chemistry by scientific men without distinction of nationality. It is the first occasion on which it has been awarded to a British man of science, the former distinguished Foreign Chemists being Fischer (of Berlin), Cannizzaro (of Rome), and Graebe (of Geneva).

International Book Circular.—We have received from Messrs. Williams and Norgate No. 139 of their International Book Circular; amongst other matters of interest it contains a special article by Dr. M. O. Forster, Assistant Professor at the Royal College of Science, entitled "Some Contemporary Foreign Chemists," together with an exact bibliography of their publications and a double plate of their portraits. The list comprises such well-known men as Richter, Ladenburg, Kiliani, Jüptner von Jonstorff, Beilstein, Liebermann, König, Barbier, R. Meyer, Kahlbaum, Roozeboom, van't Hoff, Von Baeyer, Biedermann, Berthelot, Erdmann, Fischer, Lunge, Ostwald, and Moissan. It is hardly necessary for us to point out the great value of such a publication, which Messrs. Williams and Norgate are willing to send to anyone on application.

MEETINGS FOR THE WEEK.

MONDAY, 19th.—Society of Arts, 8 (Cantor Lectures), "Musical Wind Instruments," by David James Blaikley.
TUESDAY, 20th.—Society of Arts, 8, "Street Architecture," by Thomas Graham Jackson, R.A.
WEDNESDAY, 21st.—Microscopical, 8, "Theory of Highly Magnified Images," by J. W. Gordon.

ELECTROLYTIC ANALYSIS OF COBALT AND NICKEL.*

ROBERT MOULTON PERKIN and W. C. PREBBLE.

CONSIDERING the large amount of work which has been done upon the electrolytic analysis of both cobalt and nickel, it might at first sight seem superfluous to endeavour to find any new methods or to undertake fresh work upon the subject. As a matter of fact our first experiments were not carried out so much with the object of finding new methods of analysis, but had for their aim the deposition of cobalt in a bright, and at the same time quantitative, manner.

All who have worked upon the electrolytic analysis of cobalt and nickel cannot fail to have been struck with the difference in appearance of the deposited cobalt and nickel. Thus, while it is easy to obtain brilliant deposits of nickel, which at the same time give quantitative analytical numbers, cobalt is usually dark and burnt in appearance, and the analytical results are almost invariably too high. It is strange that very few books dealing with electrolytic analysis refer to this remarkable difference between the two metals. Nor again, is any reference—as a rule—made to the fact that, whereas the deposited cobalt dissolves in moderately strong nitric acid with the greatest ease, the nickel deposit, although it may commence to dissolve readily, apparently becomes passive, and it is often extremely difficult to get the whole of the metal dissolved off the electrode. We will first of all describe the experiments undertaken with cobalt and leave those in connection with nickel to the end of the paper.

Cobalt.

In our first experiments, when attempting to obtain bright deposits of cobalt, thinking that perhaps the dark colour was due to slight superficial oxidation, we tried the effect of the addition of various reducing agents. The reducing agents tried were formaldehyde, formic acid, hydroxylamine, lactic, sulphurous, and hypophosphorous acids; the acids generally being employed in the form of their ammonium or sodium salts, and the solution kept alkaline by addition of ammonium hydrate. With the exception of hypophosphorous acid, the deposits obtained in presence of the reducing agents were extremely dark and sooty in appearance. But with sodium hypophosphite deposits of extraordinary brilliancy were obtained.

Sodium Hypophosphite.—The solution was made up by dissolving 5 grms. of ammonium sulphate and 1 grm. of the cobalt salt in a little water, adding 1.5 grm. sodium hypophosphite and 30 c.c. of ammonium hydrate (sp. gr. 0.88), the solution then being made up to 130 or 140 c.c. with distilled water. The mixture was then electrolysed with a C.D. of about 0.5–1.0 ampere per square decimetre, the temperature being kept at 35° to 40° C. Although the deposit obtained was extremely brilliant, the results were invariably too high, and did not even agree very well among themselves. The theoretical amount of metallic cobalt in cobalt ammonium sulphate, the salt used, is 14.94 per cent; the following three numbers show how far the results varied from the calculated value, 15.98, 16.26, and 15.84.

In order to ascertain, if possible, what caused these abnormal results, the deposits were dissolved in nitric acid and tested with ammonium molybdate. A voluminous yellow precipitate was produced, showing the presence of phosphorus. In fact the brilliant metallic deposit was a phosphor cobalt containing about 5 per cent of phosphorus.

We endeavoured to employ a somewhat similar solution to the one above described, for plating purposes, but found the deposit to be too brittle, so that we could not obtain deposits of any degree of thickness without the deposited metal exfoliating.

Acidulation of Cobalt and Tartrate.—A long series of experiments was then carried out, using solutions of the salts of various organic acids. The only two, however, which gave at all satisfactory results were ammonium oxalate and tartrate. From the point of view of appearance the tartrates give far better results than the oxalates; from quantitative considerations there is very little to choose between them. It will be noticed from the tables given that the results are almost invariably too high; this—in the case of tartrates—usually attributed to the presence of small quantities of carbon being deposited along with the metal. We consider that both with oxalates and tartrates traces of carbon are generally deposited along with the metal. In order to obtain a bright appearance a low C.D. should be employed until the bulk of the metal has been deposited. By attending to this condition the tartrates usually, but not invariably, give a very bright deposit, which at times has the appearance of burnished platinum. Generally speaking, with the oxalates the results obtained are not very bright, and the deposited metal is often very much burnt in appearance. Tables I. and II. give the results obtained by these two methods. The current density in all cases is calculated to 1 square decimetre of surface. Flag electrodes of platinum sheet were usually employed.

One very remarkable point in the electrolytic deposition of cobalt is, that sometimes a poor and unsightly deposit will give better analytical results than a bright one. Carrying out the electrolysis rapidly or slowly seems to affect the results very little. For example, in Table I. the last result but one from the bottom was carried out in less than two hours, and yet the amount of cobalt found was too high. On the other hand, all the results in Table II. which were conducted overnight were considerably too high.

Ammonia and Ammonium Borate.—A solution containing 3 to 4 per cent of ammonium borate and 30 per cent of ammonium hydrate (sp. gr. 0.88) was then tried. With this solution the resulting deposit is almost invariably brown and burnt, but as is seen from Table III., the analytical results are distinctly better than those obtained from solutions containing either the ammonium oxalate or tartrate. The borate solution was generally made up in bulk by dissolving 30 to 40 grms. of ammonium borate in 700 c.c. of water, and then making up to 1 litre with ammonium hydrate (sp. gr. 0.88). The cobalt salt was dissolved in about 50 c.c. of water, and from 30–50 c.c. of the above solution added to it, after which the solution was made up to the required volume and electrolysed. If during the electrolysis a black anode deposit was obtained, the addition of 5 or 10 c.c. of strong ammonia, or of 0.1 to 0.2 grm. hydroxylamine sulphate or hydrochloride, caused it to dissolve off, but the sulphate acts best.

It will be noticed that on one occasion the electrolysis was conducted for twenty-five hours, and on two others for twenty hours. This was not because such a long time is necessary to completely deposit the metal, but in order to see whether the results would be too high under these conditions; it will be seen that the length of time occupied in the electrolysis appears to have no influence upon the quantitative results.

Although the numbers obtained from the borate solution are a very decided improvement on those obtained from the other solutions already described, they still, from an analytical point of view, leave a good deal to be desired.

Phosphates and Free Phosphoric Acid.—We then tried a solution containing an alkali phosphate and a small quantity of phosphoric acid. With this solution very satisfactory results have been obtained; not only is the deposit bright, but the analytical numbers are also good.

In carrying out this process it was found that only a

small quantity of ammonium or sodium phosphate may be added; otherwise, the double salt of cobalt and the alkali phosphate is precipitated, and when once precipitated it can only be re-dissolved again with great difficulty. The following method of procedure gave the most satisfactory results:—About 1 gm. of the cobalt salt was dissolved in about 50 c.c. of distilled water, and then 5 c.c. of a 5 per cent solution phosphoric acid added. To this solution 25 c.c. of a 10 per cent solution of ammonium dihydrogen phosphate, $(\text{NH}_4)_2\text{H}_2\text{PO}_4$, or better, sodium dihydrogen phosphate, $(\text{NaH}_2\text{PO}_4)$, was added; the solution was then made up to 130 c.c. and electrolysed, a gauze flag electrode being employed as cathode. After the electrolysis has proceeded for half-an-hour or so there is usually a brown deposit of cobalt oxide on the anode. In order to dissolve this deposit off, about 0.5 gm. of hydroxylamine sulphate or chloride is added to the solution, when the deposit almost immediately vanishes. Very often 0.1 gm. of the hydroxylamine salt is quite sufficient. The addition of a few c.c. of formaldehyde solution has the same effect, but the action is much slower. The anode deposit is much more marked when hot solutions are electrolysed, but there is no difficulty in removing it as already described. If the solution is heated to too high a temperature, there is a tendency for the double salt of sodium and cobalt phosphate to be precipitated out. The phosphoric acid is added in the first place to prevent the precipitation of this double salt, because if it is once precipitated a considerable quantity of phosphoric acid must be added in order to dissolve it again. But when there is too much phosphoric acid in the solution the deposition of the cobalt is extremely slow. It is, in fact, always an advantage, after the bulk of the cobalt has been deposited, to add a few drops of very dilute ammonium hydrate to neutralise the excess of acid liberated by the electrolysis. The last examples in the table only had 1.3 c.c. of a 5 per cent solution of phosphoric acid added, which is only about 0.02 per cent (the volume was 130 c.c.); in such cases it is not necessary to neutralise with ammonia.

It will be noticed that by employing this method for depositing cobalt, the whole of the metal can be thrown out in from three to three and a-half hours, which is considerably quicker than by any other method. It is advisable to start with a low-current density, and to increase this after the electrolysis has been proceeding for about an hour.

Nickel.

The electrolytic analysis of nickel salts from solutions containing ammonium sulphate and free ammonia is so very satisfactory that it hardly seemed worth while to try any new solutions for the analysis of this metal. In spite of this, we thought that it would be interesting to see how nickel would behave when electrolysed in solutions containing ammonium borate and ammonia, and from solutions containing an acid phosphate and phosphoric acid. With ammonium borate and ammonia the results are

extremely satisfactory. Recently, Taggart has published a paper upon the deposition of nickel from solutions containing disodium hydrogen phosphate and phosphoric acid (*Trans. Am. Chem. Soc.*, xxv., 1939). Taggart employed rather larger quantities of phosphoric acid than we have found satisfactory. He used a platinum basin as the cathode, and found it necessary to wash repeatedly down the sides of the basin to prevent the double salt of nickel and sodium phosphate from crystallising out, a proceeding which, to say the least of it, is tiresome. The results which he publishes are certainly very satisfactory.

In working on the same lines as those we found so successful in the case of cobalt, viz., adding a little free phosphoric acid to the nickel salt before adding the sodium dihydrogen phosphate and electrolysing the resulting solution, we did not obtain satisfactory results. There was a very great difficulty in depositing the last traces of the nickel, and from about thirty experiments we only obtained one really satisfactory result. We cannot therefore recommend the phosphate solution as being satisfactory for the electrolytic analysis of nickel.

Ammonium Borate and Ammonia.—We have already shown that although cobalt gives very fair analytical numbers from solutions containing ammonium borate and ammonia, the appearance of the deposit leaves very much to be desired. With nickel the analytical results, from a quantitative point of view, are magnificent, and although the deposited metal has not the brilliant burnished appearance often obtained by other methods, it is not unsightly, having a matt silver-greyish appearance. In Table V, we give some of the analytical results obtained, and from them it will be seen that from an analytical point of view no better method could be devised. The salt employed was nickel ammonium sulphate, $(\text{NH}_4)_2\text{SO}_4 \cdot \text{NiSO}_4 \cdot 5\text{H}_2\text{O}$, which contains 14.87 per cent of nickel.

As showing the exactness of the method the numbers in Table VI, obtained from a sample of ammonium nickel sulphate which had been imperfectly dried, are of interest. A 5 per cent solution was made up, and for each analysis 20 c.c. of this solution, containing 1 gm. of the salt, was taken.

Table VII. shows a series of results obtained with ammonium tartrate. With care this method can be caused to give very good quantitative yields, but the results are apt to be erratic. It is advisable to keep the current density fairly low.

From the results of our work it is clear that, although there are several methods which may very satisfactorily be employed for the electrolytic analysis of nickel, the only really satisfactory one for analysing cobalt is the one containing phosphates and free phosphoric acid. It is very remarkable that this method should, however, not give satisfactory numbers when employed for the analysis of nickel. But, so far as general analysis is concerned, even the methods which give slightly high results with cobalt

are more satisfactory than the gravimetric processes for analysing this metal, which are employed in pure chemistry.

We have not yet succeeded in devising a satisfactory electrolytic method for the separation of cobalt and nickel, and have not found the methods described in the literature to give really reliable results.

Some of the results in Table I. are due to Mr. E. G. P. Bousfield, to whom our thanks are due.

THE ELECTROLYTIC SOLUTION OF PLATINUM.

By ANDRÉ BROCHET and JOSEPH PETIT

Acids are without action on platinum; aqua regia alone dissolves it, and this mode of attack, due to the formation of chlorine, is relatively slow if the metal has been melted or rolled.

Platinum utilised as an anode is unattackable in most cases; the electrolysis of hydrochloric acid and of the chlorides, however, has an action which is far from being negligible.

The transformation of the chlorates into perchlorates is accompanied by transportation, more or less distinct, from the anode to the cathode.

(*Zeit. f. Elektrochemie*, 1903, vol. ix., p. 235), who found that the addition of a continuous current to the alternating one caused the platinum to be dissolved to an appreciable extent. An analogous result was obtained by using the alternating current in the presence of oxidising agents, particularly chromic acid.

Following up our researches on electrolysis by means of alternating currents (*Bull. Soc. Chim.*, [3], 1904, vol. xxxi., p. 359), we decided to examine the solution of platinum in the cyanides, a solution which is of much more importance than that mentioned by the preceding authors.*

We have already examined the electrolysis of cyanide of potassium with an anode of platinum. We know that under these conditions the metal is completely insoluble; it is a strip of platinum that is used as the anode in hot gilding, and the operator plunges this electrode in, to a greater or less extent, according to the intensity of the current and the effect of colouration he desires to obtain. Cyanide of potassium is decomposed with the formation of potash, ammonia, and carbonic anhydride.

Cyanide of Potassium.—For the examination of the solution of platinum under the influence of an alternating current, we have made use of a small narrow apparatus in which are placed two strips, 1 c.m. in width and 0.1 m.m. in thickness, dipping 5 c.m. into the electrolyte. This latter consisted of a solution of cyanide of potassium at 4 grm.-molecules per litre (15 c.c.).

Too rapid heating, caused by the high density of the

De la Rive (*Comptes Rendus*, 1837, vol. iv., pp. 835 and 909) observed that if we pass an alternating current through a sulphuric acid voltameter, the electrodes become rapidly changed; there is no solution effected, but simply the formation of platinum black.

This manner of behaving with an alternating current has been confirmed by other writers who have studied the question. Drechsel (*Journ. f. Prakt. Chem.*, [2], 1879, vol. xx., p. 378; 1880, vol. xxii., p. 476), when examining the hydration of carbonate of ammonium under the influence of an alternating current, observed the solution of the platinum and the formation of different salts (*Journ. f. Prakt. Chem.*, [2], 1882, vol. xxvi., p. 257) which were examined by Gerdès.*

More recently, Margules (*Ann. der Chemie und Physik*, [2], 1898, vol. lxxv., p. 629; vol. lxxvi., p. 540) undertook, in a purely qualitative manner, the examination of the action of the alternating current on platinum in the presence of various electrolytes; his researches were resumed by Ruer

current, was prevented by placing the apparatus in a recipient full of water.

The results obtained are given in Table I. The return is obtained, as in our previous researches, from the ratio between the weight of platinum dissolved and the weight calculated for the total amount of electricity passing through the apparatus during the time of the experiment.

We see from Table I. the importance of the solution as soon as we exceed half a grm. per ampère-hour.

On continuing the action of the current the strips of platinum gradually dissolve, the liquor becomes heated, and, on cooling, the colourless solution deposits yellow crystals of platino-cyanide of potassium, appearing green by reflected light. The reaction is as follows:—

With a density of current of 40 ampères per square decimetre, we can dissolve approximately a thickness of 1/10th of a m.m. per hour; with 80 ampères only twenty-five minutes are required.

Cyanide of Barium.—Platinum behaves in the same

* Dannel (*Zeit. f. Elektrochemie*, 1890, vol. vi., p. 275) mentioned the preparation of identical salts by Erdmann. He gave no reference, however, and we have not been able to find the paper. We are, however, of the opinion that the work, attributed by mistake to Erdmann, is none other than that of Gerdès.

* Let us remark that when operating under the ordinary conditions of our experiments, the solution of platinum in hydrochloric acid is about 1 per cent, or about 0.04 grm. per ampère-hour.

manner in a solution of cyanide of barium. Our experiments were carried out on wire 2 m.m. in diameter, plunged about 9 c.m. into a solution of cyanide of barium containing about 2 gm.-molecules per litre. We obtained the results shown in Table II.

As with cyanide of potassium the solution is effected very easily, but with a smaller return. The solution remains perfectly colourless, but it soon becomes cloudy owing to the formation of carbonate of barium.

The principal reaction taking place is the following:—

As in the electrolysis by means of a continuous current, there is a decomposition of the cyanide, with the formation of carbonic anhydride and ammonia.

We have also observed the production of nitric acid, collected in the last residuary waters in the form of nitrate of barium.

If the solution becomes heated, the hydrate of barium and the platino-cyanide remain in solution, and are deposited on cooling.

Conclusions.—Platinum, therefore, is dissolved easily in cyanides under the influence of an alternating current. This point is the more interesting as this metal offers a special resistance to chemical reagents.

The cause of this solution, which could not have been predicted, appears to us to be of great theoretical interest. Our researches have led us to the establishment of a process for the manufacture of platino-cyanides, particularly that of barium, of which we propose to give fuller details later on.

We will simply remark here that the present process consists in forming successively platonic and platinous chlorides, and platino-cyanides of potassium and of copper. Finally, this latter salt is treated with baryta water.

These operations are long and troublesome on account of the impurities which have to be eliminated.

By our method the platinum is dissolved directly in the cyanide of barium, it suffices then to filter and crystallise the salt.

As for the amount of electric energy used, it is very small; it corresponds approximately to eight kilowatt-hours per kilogram. of platino-cyanide of barium obtained. —*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 12.

HYDRONITRIC ACID AND THE INORGANIC TRINITRIDES.*

R. I. M. DENNIS and A. W. BROWN†

(Continued from p. 308.)

II. EXPERIMENTAL (continued).

(b) The Preparation of Sodium Trinitride from Sodium Amide.

In his original work upon the method, W. Wislicenus (*Ber.*, xxv., 2084) prepared sodium trinitride by passing nitrous oxide over sodium amide heated to a temperature of between 150° and 250°. He obtained a yield equal to 50 per cent of the theory called for by the equation $3\text{NaNH}_2 + \text{N}_2\text{O} = \text{NaOH} + \text{NaN}_3 + \text{NH}_3$.

Szarvasy (*Journ. Chem. Soc.*, lxxvii., 603) worked between the temperatures of 190° and 220° and obtained a yield of 56 per cent.

In the early work done in this laboratory the temperature varied between 210° and 225°. As the thermometer was usually from 1 to 3 inches above the nickel dish in the iron can, the actual temperature of the amide was probably somewhat higher. In one experiment the attempt was made to bring the bulb very close to the surface of the amide. As a result, the bulb broke during the course of the experiment, probably because it came in contact with the molten amide, and the mercury upon dropping into the amide caused a violent explosion that completely

wrecked the apparatus. The best method of securing accurate temperature measurement in this work would probably be to encase the thermometer bulb in a polished nickel tube, closed at the lower end, and then submerge it in the molten amide. In our later work, however, the thermometer was simply placed outside the nickel dish within the can, so the bulb was on a level with the amide.

In this way fairly accurate measurements were possible.

The yields of sodium trinitride obtained in the early work here were very low, seldom rising above 5 per cent of the theory, even when the amide used was of a high grade of purity. Consequently, some years ago Mr. Edward Hirshfield undertook, in this laboratory, a careful study of the process, and found that the low yield was not attributable either to leakage of air or moisture into the apparatus, or to the catalytic action of the nickel crucible.

Mr. Hirshfield then noticed that small portions of the product adhering to the bottom of the inlet tube were of an appearance quite different from that of the rest of the mass, and showed a percentage of sodium trinitride in one case equal to 79 per cent of theory, while the main mass showed no more than 2 per cent. This at once suggested a consideration of the influence of temperature upon the reaction. The product scraped from the inlet tube had undoubtedly been formed at a lower temperature than that to which the contents of the crucible had been subjected. It had a crumbly appearance, as though it had solidified as soon as formed, while the contents of the crucible gave the appearance of having been perfectly fused.

A series of four experiments was now conducted in which, to facilitate observation and to enable quick regulation of temperature, a long combustion tube, bent upwards at the ends, was used. In each case a quantity of the amide, broken into small pieces, was introduced into the tube, which was then cautiously heated in a combustion furnace until the amide was in a state of perfect fusion. As anticipated, the greenish liquid began slowly to change to a white solid, the transformation beginning at the end of the tube nearest the nitrous oxide generator and proceeding toward the other end. If during the process any portion of the tube became slightly overheated, there would result a violent rush of gas and a local ignition confined to the limited area that has been overheated. This could instantly be checked by shutting off the supply of nitrous oxide. The results of these four experiments are shown in Table III. In Nos. 1, 2, and 3 several local ignitions were observed to take place. In No. 4 their occurrence was prevented by regulating the temperature with extreme care.

TABLE III.

	Grms. AgCl per gm. product	Percentage yield of NaN ₃
1	1.0086	74.0
2	1.1177	82.0
3	0.9405	69.0
4	1.2376	90.8

The results of these experiments seem to show that the low yield in the previous runs was due probably to the secondary reaction between nitrous oxide and sodium trinitride, this action taking place with almost explosive violence at temperatures above a certain limit, and to some slight extent perhaps even at comparatively low temperatures.

To further test this assumption, Mr. Hirshfield conducted several experiments upon weighed amounts of carefully prepared sodium trinitride. In each case the substance was placed in a porcelain boat and introduced into a combustion tube as close as possible to the bulb of the thermometer. Heated for one hour in a current of nitrous oxide to a temperature of between 200° and 205°, the sodium trinitride remained unchanged in appearance except that it became slightly darker. Analysis showed, however, that it had lost about 5 per cent of its nitrogen. In another experiment the temperature was gradually

* From the *Journal of the American Chemical Society*, xxxvi., No. 6.

raised. Before fusion could take place there was a bright ignition, accompanied by a violent rush of gas. A small amount of metallic sodium sublimed along the walls of the tube, and the boat, which had been considerably attacked during the experiment, was found to contain a white substance, soluble in water, and yielding fumes of nitrogen peroxide on acidification with sulphuric acid. In the next experiment care was taken to free the nitrous oxide from any of the higher oxides of nitrogen that it might contain by passing it through a strong solution of potassium hydroxide. Notwithstanding this precaution, acidification of the product with sulphuric acid gave the same result as before. Tests for hyponitrites gave negative results. The product was finally decided to contain sodium nitrite, which was probably formed in accordance with the equation $\text{NaN}_3 + 2\text{N}_2\text{O} \rightarrow \text{NaNO}_2 + 3\text{N}_2$.

When heated in a current of pure nitrogen, sodium trinitride was decomposed before it reached its melting-point. The process of decomposition was accompanied by a violent evolution of gas, but by no ignition. Only metallic sodium remained in the boat.

As a consequence of these experimental results the temperature of 190° was adopted by the authors for the conversion of sodium amide into sodium trinitride. The temperature may be allowed to vary 3° or 4° from this point without materially influencing the result.

In the hope of shortening the process by increasing the surface of contact between the reacting substances, as was done in the preparation of sodium amide, the attempt was made to bubble the nitrous oxide through the molten amide. Two experiments convinced us that this could not be done without stoppage of the inlet tube, due to the formation there of the solid products of the reaction.

To determine the percentage yield of sodium trinitride, the product is dissolved in considerable water barely acidified with sulphuric acid and made up to a known volume. In measured portions of this solution the hydronitric acid is then determined by the method of Dennis (*Journ. Am.-Chem. Soc.*, 1896, xviii., 947). This consists in precipitating the hydronitric acid with silver nitrate, collecting the silver trinitride upon a hardened filter, washing with cold water until the wash-water gives no reaction for silver, dissolving the precipitate upon the filter with dilute, hot nitric acid, adding hydrochloric acid to the solution thus obtained, and collecting and weighing the resulting silver chloride. This method was used in obtaining the results given in Table III. Curtius (Curtius and Rissom, *Journ. Prakt. Chem.* [2], lviii., 261) determined hydronitric acid by distilling the substance to be analysed with sulphuric acid, and catching the distillate in a measured excess of tenth-normal potassium hydroxide solution. Other volatile acids must, of course, be absent. West (*Journ. Chem. Soc.*, lxxvii., 705) modified the method of Curtius by using a measured excess of tenth-normal sulphuric acid to drive off the hydronitric acid from the solution of (say) its sodium salt. The amount of sulphuric acid used was then determined by titrating back with tenth-normal sodium hydroxide. Here, again, no volatile acid other than hydronitric acid may be present.

(c) The Preparation of Hydronitric Acid from Sodium Trinitride.

To prepare free hydronitric acid the aqueous solution of the mixture of sodium hydroxide and sodium trinitride, obtained by the action of nitrous oxide upon sodium amide, is placed in a distilling flask and a few drops of litmus solution are added. A separatory funnel is then inserted in the neck of the flask and the side tube is connected with a condenser, and the condenser with a receiving flask containing a little water. The solution is then heated nearly to boiling, and sulphuric acid (1 : 1) is slowly introduced through the separatory funnel until the acid is in excess. Distillation is continued as long as the distillate gives the reaction for hydronitric acid with silver nitrate.

SUMMARY.

For the convenience of the reader the method for the preparation of hydronitric acid that has finally been adopted as the result of our examination of the process may be summarised as follows:—

One hundred grms. of metallic sodium are placed in a nickel dish and heated in the iron can, previously described, to a temperature of about 350° in a current of pure ammonia gas, that is first dried by passing it through soda-lime and fused sodium hydroxide. During this process the temperature must not be allowed to fall below 250° . The inlet tube, through which the ammonia enters, is pushed down beneath the surface of the sodium as soon as that metal melts, so that the gas may bubble up through the liquid. When the reaction is nearly complete (from five to seven hours) the inlet tube is raised out of the liquid. The flow of ammonia gas should be steady to prevent the rise of sodium in the inlet tube. In any case it is well to guard against the danger due to sudden stoppage by providing the inlet tube at some point outside of the iron can with a perpendicular side tube dipping into mercury. The end of the reaction is shown by the absence of hydrogen in the gas escaping from the can. Hydrogen in this escaping gas may be detected by collecting the gas in a test-tube by displacement, closing the tube with the thumb, and immersing the mouth of the tube in water to absorb the ammonia, and then bringing the residual gas in the test-tube into contact with a flame. When no inflammable gas is present in the tube, the operation may be regarded as complete. The apparatus is then allowed to cool nearly to the temperature of the room. It has been found inadvisable to treat all of this product in one operation with nitrous oxide because of the tendency to "creep" shown by the sodium trinitride. Consequently, about three-fourths of the sodium amide resulting from the above operation is removed and placed in a desiccator over metallic sodium.

The iron can containing the remainder of the sodium amide in the nickel dish is now connected with an apparatus furnishing dry nitrous oxide, the arrangement

FIG. 2.

being that shown in Fig. 2. This gas is made by heating ammonium nitrate. The ammonium nitrate is contained in the flask A resting on an iron plate and heated by a single Bunsen burner. The outlet tube B slopes downward and carries a two-way stop-cock, C, and the branch tube D, and at the end is bent down and inserted in a test-tube, E. The test-tube D is about 30 c.m. long and is immersed to the depth of not more than 1 c.m. in mercury that stands in the bottom of the small cylinder, F. This arrangement serves to collect in F water that may flow down the side tube D, and furnishes also a safety-valve for the release of pressure whenever stoppage occurs in the tube W. The object of this device is to catch most of the water evolved in the decomposition of the ammonium nitrate, preventing, on the one hand, the passage of the large amount of moisture into the drying agents beyond, and on the other hand, the return flow of the condensed moisture into the flask A. During the operation the two-way stop-cock C stands in such a position that the flask communicates with the drying agents beyond. Whenever

it is desired to stop the flow of nitrous oxide through the apparatus, the stop-cock is turned to such a position as allows the escape of the gas through its lower end. The test-tube *E* serves to collect the condensed water that may have passed beyond the side arm *D*. The outlet tube from *E* is connected with U-tubes, *L*, *M*, containing soda-lime, and beyond these are three U-tubes, *N*, *O*, *P*, containing fused sodium hydroxide. The gas then enters the inlet tube *W* of the apparatus *R*, which has already been shown in Fig. 1.

The generation of the nitrous oxide is now begun, and when all air has been displaced from the apparatus the iron can is heated to a temperature of 190° . In this part of the operation the gas is not bubbled through the molten amide, because the product is solid and would cause stoppage of the tube. The conversion of the 25 grms. of sodium amide takes about five hours. The end of the reaction is indicated by the absence of ammonia in the gas escaping from the outlet tube of the can. When the conversion is complete, the flame under the can is extinguished and the contents of the nickel dish is allowed to cool in a current of nitrous oxide. The cold product, consisting of a mixture of sodium trinitride and sodium hydroxide, is then dissolved in water. Hydronitric acid is distilled off in the manner previously described.

If the process has been properly conducted, no gas will be evolved when the final product is dissolved in water.

B.—The Composition of Lithium Inorganic Trinitrides.

Lithium Trinitride and Barium Trinitride. In the course of the investigation by Dennis and Doan (*Journ. Am. Chem. Soc.*, xviii., 970) upon the compounds of thallium a large amount of pure hydronitric acid had been prepared by a modification of the Wislicenus method, but no systematic study of the compounds of the acid with inorganic bases was entered upon because of the expressed reservation of this field by Curtius (*Journ. Prakt. Chem.*, xliii., 208) in 1891. When, however, seven years had elapsed without the appearance of any publication by Curtius on the inorganic trinitrides, it was thought that this branch of the field might, without discourtesy to the discoverer of hydronitric acid, be regarded as open to other investigators. Consequently, there appeared in 1898 an investigation carried on in this laboratory by Dennis and Benedict (*Journ. Am. Chem. Soc.*, xx., 225; *Zeitschr. Anorg. Chem.*, xvii., 18) upon the salts of hydronitric acid. Curtius, however, had evidently considered that his reservation of this field was a perpetual one, for, in an article with Rissom (*Journ. Prakt. Chem.*, 1898, lviii., 261) upon the inorganic trinitrides, published shortly after the appearance of the investigation by Dennis and Benedict, he courteously refers to their work in the following words: "In neuester Zeit, nach dem Abschlusse unserer Untersuchungen haben Dennis und Benedict mitgeteilt, dass sie das Bedürfnis gefühlt haben, 'ein systematisches Studium der Verbindungen der Stickstoffwasserstoffsäure' zu beginnen und in einer Abhandlung die Resultate mitgeteilt (*Zeitschr. Anorg. Chem.*, xvii., 18), welche sie bei der Untersuchung der Elemente der Alkali- und Erd-alkalimetalle erhielten."

Dennis and Benedict prepared the trinitrides of lithium, sodium, potassium, rubidium, and cesium by dissolving the respective hydroxides in hydronitric acid, and the trinitrides of calcium, strontium, and barium by dissolving the respective oxides in hydronitric acid. They stated that all of these compounds crystallised without water of crystallisation, except those of lithium and barium, to the first of which they assign the formula $\text{LiN}_3 \cdot \text{H}_2\text{O}$, and to the second $\text{BaN}_6 \cdot \text{H}_2\text{O}$. Curtius and Rissom, in the article above quoted, state that all of these trinitrides are without water of crystallisation, and advance in proof of that statement analyses of lithium trinitride and barium trinitride that show fairly good agreement with the results calculated for the anhydrous salts. Before making their analyses, however, they dried the lithium trinitride over sulphuric acid to constant weight. They did the same with the

barium salt, but analysed also an air-dried sample of that compound, and claim that the analyses of both products showed that barium trinitride is free from water of crystallisation. Dennis and Benedict had no intention of giving the impression that they considered it impossible to dehydrate the trinitrides of lithium and barium by long-continued drying over concentrated sulphuric acid, nor did they suppose that analyses of salts dried in this manner would give a correct idea of the composition of those compounds as they separate from solution. To make sure, however, that water of crystallisation is present in the two salts in question, Mr. J. H. Pettit prepared, in this laboratory, fresh portions of the trinitrides of barium and lithium, drying these samples in air between sheets of filter-paper, and then over night in a desiccator containing calcium chloride. His analyses gave the following results:—

TABLE IV.

I	Calculated for.		Found.	
	LiN_3	$\text{LiN}_3 \cdot \text{H}_2\text{O}$	I	II
	Percent	Percent	Percent	Percent
	44.29	40.40	40.82	40.88
	BaN_6	$\text{BaN}_6 \cdot \text{H}_2\text{O}$	I	II
	Percent	Percent	Percent	Percent
Ba. .	66.96	57.32	57.16	57.31

To ascertain whether the air-dried, hydrated barium trinitride would lose water of crystallisation on standing over sulphuric acid, 0.2429 gm. of the air-dried salt was allowed to stand for two months in a desiccator containing sulphuric acid. The amount of water contained in the above-mentioned weight of $\text{BaN}_6 \cdot \text{H}_2\text{O}$ is 0.0184 gm. The salt lost, on standing, over the sulphuric acid 0.0182.

The above analyses confirm the statement of Dennis and Benedict that lithium trinitride and barium trinitride, as crystallised from aqueous solutions, contain each one molecule of water of crystallisation.

Silver Trinitride.—Curtius (*Ber.*, 1890., xxiii., 3023) states that silver trinitride is insoluble in water and dilute acids. Both of these statements are incorrect. As pointed out by Dennis (*Journ. Am. Chem. Soc.*, 1896, xviii., 947), silver trinitride is soluble in dilute, hot nitric acid, and recent experiments by the authors have shown that the compound is also somewhat soluble in boiling water (about 0.1 gm. in 1 litre of water), and that it crystallises in minute needles from this solution. This crystalline form of silver trinitride has already been mentioned by Angeli (*Atti. R. Accad. dei Lincei Roma*, 1893, [5], ii., 1., 569).

(To be continued.)

NOTE ON THE ELECTROLYTIC PREPARATION OF TITANOUS SULPHATE.

By W. H. EVANS, B.Sc.

DESPITE the important applications of the titanous salts during the last few years, and the fact that they are now prepared technically by electrolysis,* no data have been published to show the influence upon the yield of varying the conditions of working. It seemed, therefore, of some interest to investigate the effect of the current density, concentration of solution, and temperature at which the electrolysis is carried out, upon the course of this electrolytic reduction. Up to the present only titanium sulphate has been dealt with.

In the earlier work the solutions were electrolysed in a beaker, with a porous pot to separate the anode from cathode chambers, but it was soon found that the solution of titanous sulphate, despite the very powerful reducing properties of this compound, is quite stable, and that very

* Howard Spence and P. Spence, *and* S. J. Fox, *Patents* No. 15,196 and 15,630 of 1902.

good yields could be obtained without the use of any diaphragm. Provided the current density at the anode is kept fairly high, the oxygen is evolved without effecting any marked oxidation of the titanous salt. This, of course, considerably simplifies the preparation, and in all the later work the electrolysis was carried out in a beaker or vat in which the electrodes were suspended at some distance apart. Moreover, the P.D. required is much lower owing to the smaller resistance of the cell (2·5 to 3·5 volts instead of 4 to 5 volts).

Effect of Varying the Current Density.—With a solution containing 40·8 grms. titanium sulphate per litre in a beaker containing 400 c.c., with a current of 3·5 ampères (=14 ampères per 100 sq. cms.), the yield at 20 minutes after starting was 31 per cent, after 33 minutes 22 per cent.

With the same solution, but with only 1·7 ampères (=6·8 ampères per 100 sq. cms.), the yield at corresponding times was 62 and 50 per cent respectively. That the yield falls rapidly with increase of current density was fully borne out by the results of a series of preliminary experiments, using a porous pot.

Influence of Temperature.—It was found that by raising the temperature at which electrolysis was carried out the yield could be considerably increased. The comparative experiments were arranged by connecting two electrolytic cells containing the same solutions (81·6 grms. $\text{Ti}(\text{SO}_4)_2$ per litre) in series. One cell was kept at 70° C., the other as near 0° C. as possible. At the higher temperature, with a current density of 4·5 ampères per 100 sq. cms., the yield could be kept above 70 per cent until quite half of the titanium sulphate had been reduced.

In the cold solution, on the other hand, the yield was only about 45 per cent of the theoretical; the difference in the two cases was very clearly seen in the fact that there was no visible evolution of hydrogen at the cathode in the hot solution, whereas in the cold a considerable amount of hydrogen was given off.

Effect of Concentration.—In the preliminary experiments, using a porous pot to separate the anode from the cathode, the influence of concentration within the limits of 85 to 17 grms. of titanium sulphate per litre was very evident, for with a current density of about 7 ampères per 100 sq. cms., and a temperature of 15° to 17° C., the yields were as follows:—

1. Solution containing 85 grms. $\text{Ti}(\text{SO}_4)_2$ per litre, 75 per cent.
2. Solution containing 42·5 grms. $\text{Ti}(\text{SO}_4)_2$ per litre, 33 per cent.
3. Solution containing 17 grms. $\text{Ti}(\text{SO}_4)_2$ per litre, 2·2 per cent of the theoretical for the current used.

In comparative experiments in which platinum electrodes were substituted for those of lead no very great difference in yield could be observed, possibly with lead better results were obtained.

The estimation of the amount of titanous salt obtained was carried out by titrating a small quantity of the solution from the cell with standard permanganate, after warming to 60° or 70° C.

In all the experiments the cathode solution was well stirred, either by a mechanical stirrer or by passing a current of some inert gas.—*Memoirs and Proceedings of the Manchester Literary and Philosophical Society*, xlix., Part I.

Royal Institution.—On Tuesday next (December 27), at 3 o'clock, Mr. Henry Cunyngame will deliver the first of a Christmas course of six lectures, adapted to a juvenile auditory, on "Ancient and Modern Methods of Measuring Time" (Experimentally Illustrated). The following are the subjects for the lectures:—Ancient Sundials and Clocks, the Discoveries of Galileo, the Pendulum and Balance-wheel, How a Clock is Made, More about Clocks and Watches, Quick Time Measurements of the Speed of Cannon-balls and of Light.

LONDON WATER SUPPLY.

REPORT ON THE COMPOSITION AND QUALITY OF DAILY SAMPLES OF THE WATER SUPPLIED TO LONDON FOR THE MONTH ENDING NOVEMBER 30TH, 1904.

By SIR WILLIAM CROOKES, F.R.S.,
and
SIR JAMES DEWAR, F.R.S.

To CHARLES PERRIN, ESQ., M.Inst.C.E.,
Water Examiner, Metropolitan Water Act, 1871.

London, December 9th, 1904.

SIR,—We submit herewith, at the request of the Metropolitan Water Board, the results of our analyses of the 212 samples of water collected by us during the past month, at the several places and on the several days indicated, from the mains of the Metropolitan Water Board taking their supplies from the Thames and Lea.

In Table I. we have recorded the analyses in detail of samples, one taken daily, from Nov. 1st to Nov. 30th inclusive. The purity of the water, in respect to organic matter, has been determined by the Oxygen and Combustion processes; and the results of our analyses by these methods are stated in columns XIV. to XVIII.

We have recorded in Table II. the tint of the several samples of water as determined by the colour-meter described in previous reports.

In Table III. we have recorded the oxygen required to oxidise the organic matter in all the samples submitted to analysis.

Of the 212 samples examined by us during the month, all were clear, bright, and well filtered.

The rainfall at Oxford during the month has been below the average; the actual amount recorded was 1·59 inches. The average for November is 2·30 inches, leaving a deficit of 0·71 inch, which, if added to the previous deficit of 1·61 inches, gives a total deficit for the year of 2·32 inches, or to per cent on the thirty-five years' average.

Our bacteriological examinations of 378 samples taken during the month have given the results recorded in the following table. Besides these samples we have examined 395 others from special wells, standpipes, &c., making 773 samples in all:—

	Microbes per c.c.
New River, unfiltered (mean of 26 samples) ..	200
New River, filtered (mean of 77 samples) ..	8
Thames, unfiltered (mean of 26 samples) ..	2407
Thames-derived water from the clear-water wells of eight Thames-derived supplies (mean of 197 samples) ..	18
Ditto ditto highest	189
Ditto ditto lowest	0
River Lea, unfiltered (mean of 26 samples) ..	236
River Lea, from the East London District clear- water wells (mean of 24 samples) ..	16

Of the 298 daily samples taken from the general filter wells of the Metropolitan Water Board, twenty-three samples, or 7·7 per cent, were sterile. Eight samples, or 2·6 per cent, contained more than 100 microbes, and of these four samples contained more than 150 microbes per c.c. The eight excess samples contained an average of 140 microbes per c.c. In October four excess samples contained an average of 130 microbes per c.c.

Considering the unavoidable fluctuations which will inevitably take place in a water supply derived primarily from two large rivers, the quality of the water distributed to London during the month of November must be characterised as excellent.

We are, Sir,

Your obedient Servants,

WILLIAM CROOKES.
JAMES DEWAR.

PROCEEDINGS OF SOCIETIES.

PHYSICAL SOCIETY.

(Ordinary Meeting, December 10th, 1901.)

Dr. R. T. GLAZIER, F.R.S., President, in the Chair.

Prof. S. P. THOMPSON read a paper "On a Rapid Method of Approximating Harmonic Degrees."

For the study of alternating electric currents and for several other applications, harmonic analysis is simplified by the consideration that all the even terms in the Fourier expansion are absent. In this case the second half-period is similar to the first half-period, but with the ordinates of the corresponding angles reversed in sign. Given a complicated harmonic curve containing constituents of the odd orders only, the zero-line can always be drawn so that the constant term vanishes from the Fourier series, the mean ordinate being zero; and it is then always possible to choose as origin a point for which the ordinates at 0° and 180° are zero.

The paper gives a *résumé* of the various methods which have been employed for harmonic analysis by reduction from simultaneous equations, graphical means, and by harmonic analysers. The method adopted by the author is a simplification of a general method of analysis published by Prof. Runge. The half-period of the wave is divided into $2m$ equal parts giving $2m-1$ equidistant ordinates. These ordinates are then put together in pairs, so that there then may be found the sum and difference of the ordinate of any angle and the ordinate of its supplement. The sum will contain sine-components only, and the difference cosine-components only. The sums are used for getting out the coefficients of sine-terms, and the differences for getting out those of the cosine-terms. A further grouping is employed for the higher harmonics of those orders for which the ordinal number is a factor of the number of division m , by means of which a saving of multiplication is effected. The numbers assembled and grouped are arranged in a convenient schedule, each number as it is entered being multiplied by the sine of the angle set over against it. The coefficients of the n th order are given by the integrals—

$$A_n = \frac{2}{T} \int_0^T y \cdot \sin npt \cdot dt \text{ and } B_n = \frac{2}{T} \int_0^T y \cdot \cos npt \cdot dt.$$

Hence it is necessary to integrate and take twice the means. The integration becomes a mere summation of the products made during the preceding processes. But since in the case where, say, 12 ordinates are taken, the 11th coefficient would be got out by multiplying by the same sines as would yield the 1st coefficient, only with alternate + and - signs prefixed, the addition for both the 1st and the 11th harmonic may be effected by finding separately the sums of the alternate product-numbers, which are therefore set down alternately in two columns. The totals of the first column and of the second column are therefore made separately. The sum of them gives the "integral" for the 1st harmonic, the difference between them gives the "integral" for the 11th harmonic, and so forth. The labour of the process varies approximately as the cube of the number of ordinates taken. Using 18 ordinates the time taken to complete the whole analysis is about seventy minutes; for 12 ordinates it is about twenty-five minutes, and for 6 ordinates under two minutes.

Dr. J. A. FLEMING said that he had found by experience that most alternating-current curves of current or E.M.F. which occurred in connection with transformer working, could be quite nearly represented by a simple sine curve added to the two first odd harmonics having wave-lengths one-third and one-fifth of the primary. Hence the analysis of any such curve as the magnetising curve of a current-transformer resolved itself simply into the determination of the amplitude and phase-difference of these three con-

stituents. They were indebted to Prof. Thompson for bringing before them such a simple arithmetical process of resolution, which reduced the performance of the Fourier analysis of simple periodic curves to little more than mere arithmetic, even more simple than Horner's process for obtaining the arithmetic real roots of an equation of the n th degree. In addition to the analysis of a single periodic curve, it was useful sometimes to be able to perform the synthesis rapidly, and Dr. Fleming exhibited and described a simple form of instrument which he had designed for effecting this. The instrument was constructed to draw the compound polar curve corresponding to a fundamental and the first two odd harmonics, and a diagram was exhibited showing the corresponding wave-form for one setting, which was extremely similar to the no-load magnetising current of a transformer. Diagrams were also exhibited showing how nearly the magnetising current of a transformer could be represented in wave-form by the use of such an apparatus. He said that the representation of alternating-current curves by polar diagrams had particular advantages, and it was much to be wished that some enterprising stationer would provide polar ruled paper for plotting polar diagrams, analogous to squared paper.

Mr. J. HARRISON pointed out that the author's system of harmonic analysis could very readily be performed entirely by graphical methods, and moreover, subject to certain restrictions, could be employed to find even terms as well as odd ones. He exhibited a graphical schedule for a particular case and demonstrated its use.

A paper on "A High Frequency Alternator" was read by Mr. W. DUBBEL.

The author described and showed in action a high-frequency alternator which he had constructed in 1900 for some experiments on the resistance of the electric arc, and with which frequencies up to 120,000 per second had been obtained. The alternator consists of an inductor, built up out of ferrotype plate, having V-shaped notches cut in its edge so as to have flat-topped teeth. Surrounding the inductor is a laminated ring having two inwardly projecting poles, the clearance between these and the teeth of the inductor, which formed the air-gap, being less than 0.1 m.m. The ring is wound so that a direct current flowing round the winding tends to produce lines of force from one pole to the other through the inductor. The number of lines of force varies from a maximum when the teeth of the inductor are opposite the poles, to a minimum when the poles are in front of the spaces. This variation in the total number of lines of force produces alternating E.M.F.'s in any winding either on the pole-pieces or on the ring itself; the movement of the inductor through the distance between two consecutive teeth producing one complete period. One winding on the ring could serve to carry both the direct current which magnetises the ring and the alternating current produced. In practice, owing to the great importance of any self-induction in the alternate-current circuit, it was found advisable at high frequencies to use separate windings for the two currents. At the highest frequencies the best results were obtained with coils having a few turns of wire fixed right on the tips of the poles. The alternator is driven by means of a figure-of-8 belt driven from two phosphor-bronze discs. Each of these discs is belted to a double-grooved pulley fixed on the shaft of a direct-current driving motor. With this method of drive the inductor was run for several months at speeds between 30,000 and 40,000 revs. per minute, and the spindle of the inductor alone could be easily run at 60,000 revs. per minute. Using inductors having 30, 60, 90, and 204 teeth, the author obtains small alternating currents having frequencies from a few hundred periods per second up to 120,000 per second. An illustration will perhaps convey some idea of how high a frequency of 120,000 per second really is. In plotting curves for ordinary frequencies of 50 to 100 per second, a scale often adopted is 10 inches for 100. If it were attempted to plot a curve up to 120,000 per second to

OBITUARY.

SIR LOWTHIAN BELL.

this scale, the curve paper would require to be 120,000 inches, or nearly *one-fifth of a mile long*. Many difficulties were encountered with the centrifugal forces on the driving-belt, and the author finally obtained the best results with a spliced cotton cord. Working drawings of the alternator, characteristic curves, and its wave-form are given in the paper. During the construction of the alternator bicycle wheels were used to drive it, and curves are given showing the very large power taken to drive these wheels, owing to air friction. A table is given of all the high-frequency alternators which have come to the author's knowledge, and he would be glad to receive any missing data or data of other machines to include in the table before it is finally printed.

Dr. J. A. FLEMING said he had felt surprised on hearing about Mr. Duddell's alternator that he had been able to reach any such frequency as 120,000 $\sim$ per second. It spoke highly of the excellent mechanical means employed. On the other hand, as far as its use in wireless telegraphy was concerned, it was no use to speak of a machine even if it gave this frequency, corresponding to a wave 14 miles in length, if the output of the machine were only a few watts. If it were 150 H.P. it might be different. The difficulty with most high-frequency alternators was the magnetic leakage. Dr. Fleming then described some of the devices adopted by Tesla for obviating this defect. Many of the high-frequency alternators made had their power overestimated. Hitherto the frequency reached had been only about 10,000 $\sim$ per second. A machine of this last frequency would be no particular assistance in wireless telegraphy. Such machines were, however, very useful for research and demonstration purposes.

Prof. W. E. AYRTON gave an Exhibition of Experiments to show the Retardation of the Signalling Current on 3500 miles of the Pacific Cable between Vancouver and Fanning Island.

The experiments were performed upon a cable electrically equivalent to the portion of the Pacific Cable between Vancouver and Fanning Island, the product of the capacity (in mfd.) and the resistance (in ohms) being nine millions. Three dead-beat galvanometers were employed to indicate the current at the beginning, in the middle, and at the end of the cable. It was shown that upon applying an E.M.F. at one end of the cable the current at that end was enormously greater than its steady value, and that one-fifth of a second elapsed before any indications of current were shown at the far end of the cable. By that time the current at the sending end was 3.7 times its steady value, and after two-fifths of a second it had fallen to 2.3 times its steady value. In about five seconds the current became steady.

The Electrical Laboratories of the College were open to the inspection of Fellows, a special feature being an exhibition of Ayrton-Mather Galvanometers (showing the evolution of the present commercial instruments from the earliest types, constructed in the College), Universal Shunts, and Electrostatic Instruments.

Purification of Sodium Vanadate Liquors. Remarks upon the Industrial Separation of Metals by Double Decomposition.—M. Herrenschildt.—In reply to a question from the Patent Office at Berlin, as to why vanadic acid rather than any other acid was used in precipitating silica from a solution of sodium vanadate, the author states that vanadic acid is the only acid which will precipitate silica from a *dilute* solution. Moreover, if sulphuric acid, for instance, is used with a concentrated solution, both vanadic acid and silica are precipitated, and there is no separation. This method of separating metals from a solution by the addition of a compound of one of them rather than by adding a foreign substance, is in use in several manufactories, e.g., zinc is separated from copper by the addition of zinc oxide, cobalt from nickel by the addition of nickel sesquioxide, &c.—*Comptes Rendus*, cxxxix., No. 21.

WE regret to announce that the veteran ironmaster and metallurgist, Sir Isaac Lowthian Bell, died at his residence, Rounton Grange, Northallerton, on Tuesday, December 20th, within a few weeks of completing his eighty-ninth year. He was born on February 15th, 1816, at Newcastle, his father being an ironmaster, Mr. Thomas Bell, and his mother a daughter of Mr. Isaac Lowthian, of Newbigin, in Cumberland. After attending Edinburgh University and the Sorbonne, he spent some time in travel on the Continent, and then, at the age of twenty-four, entered the Walker ironworks, near Newcastle, in which his father was a partner. There he remained till 1850, when he became connected with the chemical works at Washington, in North Durham. Under his direction these became one of the most important concerns of their kind in the North of England. He greatly enlarged them, and laid down extensive plant for the manufacture of an oxychloride of lead introduced as a substitute for white lead by his father-in-law, Mr. H. L. Patinson, F.R.S., with whom he was associated in the business at Washington. There, too, was introduced, in 1860, almost the first plant in England for the manufacture of aluminium by the Deville sodium process.

Soon after the discovery of the main bed of Cleveland ironstone near Middlesbrough by John Vaughan in 1850, in conjunction with his brothers, Thomas and John, he started ironworks at Port Clarence, on the north bank of the Tees. A little more than half a century ago the site of Port Clarence was a waste of mud and marsh—in fact, the Tees then flooded ground where iron furnaces now stand. Much land in the estuary has since been reclaimed—largely by means of the "cinder balls" from the furnaces, which were used to build retaining walls—and on a portion of this were placed the iron-smelting works of Bell Brothers, among the largest in the Cleveland district. From the first they were carried on in an enterprising and economical spirit. To most people the site upon which they were erected would have seemed unpromising enough, yet in fact it had facilities for land and water carriage and possibilities of extension at very reasonable expense. The firm acquired their own ironstone mines, collieries, and limestone quarries, while they have always been prompt to adopt any improvement in process or apparatus that has seemed likely to be advantageous. For example, when it was found that economy in fuel resulted from increase in the height of blast furnaces, they re-constructed their plant, in view of that fact, and they were among the first in the Cleveland district to take advantage of the saving effected by the use of the waste gases for heating the blast. In the development of the Cleveland iron industry they thus played a very important part, and what has been the extent of that development may be judged from the fact that, whereas the district in 1850 produced less than 25,000 tons of pig-iron, at the present time Middlesbrough accounts for about one quarter of the total output of this country. Not only were they largely responsible for the surveys which revealed the position and extent of the ironstone beds, but they were active in prosecuting those technical studies by which processes have been devised enabling Cleveland ores to compete as raw material for the production of iron and steel with others possessing greater natural advantages. In regard to steel, the great trouble with those ores is the high percentage of phosphorus (1.8 to 2.0 per cent) contained in the cast-iron which they yield; yet Middlesbrough, largely as a result of experiments carried on under Sir Lowthian Bell's direction, at a cost, it is said, of between £40,000 and £50,000, produces steel rails in which this percentage is reduced to 0.07 or less. Many thousand tons of such basic steel rails have been laid on the North-Eastern Railway, of which he was a director, and the careful records kept of their behaviour convinced him that

neither in loss of weight by wear nor in the number of breakages do they give any ground for complaint. In connection with rails it is interesting to note, as an illustration of the advances made during his exceptionally long and active life, that he could remember seeing wooden rails in use on the tramroads by which coal was brought down to the river Tees. Middlesbrough steel has also been rendered available for shipbuilding purposes, and as chairman of the company he had, in 1901, the satisfaction of announcing that the product of the Clarence Works fulfilled all the requirements of Lloyd's Registry.

Sir Lowthian Bell had an intimate knowledge, both on the scientific and statistical sides, of the iron and coal deposits of the North of England. When the British Association met at Newcastle in 1863, he contributed a paper on the manufacture of iron in connection with the Northumberland and Durham coalfields, in which he calculated that the supply contained in that coalfield was just about sufficient to smelt the ironstone in the main Cleveland seam, supposing none of it to be used for any other purpose. His aptitude for statistics was also shown in other ways. In 1870 he wrote a paper bristling with facts and figures, on the sanitary condition of Newcastle, and more recently he compiled an elaborate account of the iron trade of the United Kingdom, compared with that of the other chief iron-making countries. On the chemistry of iron he was a very high—if not the highest—authority. The establishment of a chemical laboratory in connection with the Clarence works shows how fully he realised the importance of the scientific study of industrial processes, and his own researches on the chemistry of iron and steel, some of which have been translated into French and German, have become classic. Many of the most important of these appeared first in the form of papers read before the Iron and Steel Institute, and a number of them were subsequently collected and published in a thick volume entitled "The Chemical Phenomena of Iron Smelting." Sir Lowthian was also the author of a book on the "Principles of Iron and Steel Manufacture," as well as of many papers contributed to other scientific societies.

In the Iron and Steel Institute he took a great interest. One of its original founders in 1869, he filled the office of president from 1873 to 1875, and in 1874 became the first recipient of the gold medal instituted by Sir Henry Bessemer the year before. Among the learned societies he was a member of the Civil Engineers and of the Chemical Society, and a past president of the Institution of Mechanical Engineers. In a presidential address to the Institution of Junior Engineers in 1900, he gave a short account of the development of the iron trade, and after claiming that Great Britain had been almost the sole author of the improvements that had raised the industry to its present position, declined to admit that our reduced production was due to any inferiority in methods of manufacture. In 1874, the Royal Society made him one of their number, and he had the distinction of being elected an honorary member of the American Philosophical Institution. In the municipal affairs of Newcastle he took a prominent part, having been a member of the Town Council for many years, and having held the mayoralty twice; and he was a director of the North-Eastern Railway. He was a J.P. and D.L. for the county of Durham, and served as sheriff in 1884. He made several attempts to enter Parliament, but was somewhat unfortunate. He contested North Durham in 1868, but was defeated. Six years afterwards he stood again for the same constituency, and was returned at the head of the poll. The election, however, was held void on the ground that intimidation had been practised at certain places, and at the new election thus rendered necessary Sir Lowthian Bell was at the bottom of the poll. In the following year (1875) success attended his efforts at Hartlepool, for which he sat in the Liberal interest till 1880. The honour of a baronetcy was conferred on him in 1885, and in 1893 he received the Degree of LL.D. from Edinburgh University.

Sir Lowthian married, in 1842, Margaret, the second daughter of Mr. H. L. Pattinson, by whom he had six children. The title goes to Mr. Hugh Bell, born in 1844, whose wife, daughter of the late Sir Joseph Olliffe, M.D., is well known as the writer of several novels and of a number of plays, both in English and French, some of which have been produced in London, including *L'Indécis*, produced by Coquelin at the Royalty in 1887. One of Sir Lowthian's daughters is the present Lady Stanley of Alderley.—*The Times*.

MISCELLANEOUS.

Double Cyanides of Mercury.—Hermann Grossmann and Peter Von der Forst.—Analysis of the potassium double cyanide gives the formula $K_2Hg(CN)_4$. In the sodium salt the double molecule, $Na_2Hg(CN)_6$, exists, as is shown by determinations of the lowering of the freezing-point of water and conductivity determinations. Possibly the sodium salt in solution splits up into $Na_2Hg(CN)_4$ and $Hg(CN)_2$, the latter being a non-electrolyte. No solid ammonium compound is known. The barium and strontium salts belong to the same type as the potassium salt, but are hydrated and unstable in air. Both compounds crystallise in colourless prismatic needles. The calcium salt exists in two forms, having the formulae $CaHg(CN)_6 \cdot 3H_2O$ and $Ca_2Hg_3(CN)_{10} \cdot 6H_2O$ respectively. The magnesium salt belongs to the same type as the latter of these.—*Berichte*, xxxviii., No. 15.

Withdrawal of Oxygen by Platinum.—E. Goldstein.—It has been observed that in Geissler tubes the substance of the platinum cathode is gradually removed to the glass wall, and there forms shining mirrors, which up to a certain thickness are translucent. Mirrors which show the colours of the pure metal (green for gold, blue for silver, greyish black for platinum) are only obtained in hydrogen. If the gas contains oxygen the colours are impure, and as the amount of oxygen increases the colours approach nearer to those of the oxides of the metals. The author has now observed that the oxygen is absorbed very quickly if the cathode is ignited to a yellowish white heat. For pure oxygen platinum wires about 0.4 m.m. thick by a free length of about 1 c.m. are used. Such wires become intensely hot on exhaustion of the tubes, even with medium sized inductors, if a powerful primary current is applied. Thus, if a cylindrical tube of 2 to 3 c.m. width and a capacity of 50 to 100 c.c. is filled with oxygen of the usual density for Geissler tubes, if when the discharge passes the cathode glows strongly the oxygen is absorbed in one to two minutes. If the tube is filled with rarefied dry air the absorption of oxygen occurs in a still shorter time. The wires are then somewhat thinner; i.e., about 0.25 m.m. thick. The complete elimination of oxygen in any mixture of nitrogen and oxygen can be demonstrated by the fact that the discharge appears yellowish gold instead of red in nitrogen which is free from oxygen. The avidity with which platinum attracts oxygen can be used to free rarefied gases from traces of oxygen. If the pressure of the gas rises above a certain limit, the intensity of discharge obtainable for a given inductor will no longer suffice to bring the cathode to intense heat. In such cases the cathode wire (then somewhat longer) has both ends melted into the glass wall, so that it can be connected by means of external hooks with an accumulator of three cells. By means of a resistance regulator an additional current can be passed through the wire which will cause bright glowing. The method can thus be used for all densities in which a perceptible destruction of the cathode occurs, and hence there is an essential connection between the two phenomena. The energetic oxidation of the platinum is also connected with the conversion of oxygen into ozone when the discharge passes in Geissler tubes.—*Berichte*, xxxviii., No. 15.

An Improved Form of Crucible Lid.—In most school practice, an important type of experiment is the one where copper is converted into cupric oxide by means of nitric acid. This is usually done in a porcelain crucible, but it has been found that anything like uniform or even approximately accurate results have been impossible, even with the most careful workers, owing to the loss of liquid during effervescence and evaporation. The form of crucible lid is the main cause of these inaccurate results. Any liquid coming on the lid during effervescence or evaporation is led to the side, and then generally finds its way down the outside of the crucible. The improved lid has been

designed to obviate this. It is made slightly convex to the crucible, so that any liquid splashing on the lid is led back to the centre and drops back into the crucible. When lifting the lid during the experiment, it is of course necessary to lift it horizontally. The results given below show the values obtained by the use of the improved lid. They were obtained by a first-year class weighing only to the second place of decimals. The results obtained with the ordinary lids is also given. The form of the lid does not in any way interfere with its usefulness for other experiments.

Weight of Oxygen combined with 1 Grm. of Copper.

With ordinary lid		With the improved lids	
0.22 grm.	0.19 grm.	0.27 grm.	0.25 grm.

SERIAL ORDER OF THE RARE EARTHS.

By G. URBAIN and H. LACOMBE

ELEMENTS belong to the same family when their compounds of the same type are isomorphous and when they present, as a whole, the same chemical functions.

Generally speaking, such elements co-exist in their ores. In the case of the rare earths, in particular, the presence of one of them is scarcely detected without at the same time detecting the presence of all the others.

Two elements are the more closely related in proportion to the closeness of their isomorphic relations. Thus, cesium is more nearly allied to rubidium than to potassium. Without the possibility of formulating, in the present stage of our knowledge, a quite accurate law on this subject, it is probable that the elements of one family constitute the successive terms of a series, in the mathematical sense of the word. We will designate the logical order in which the elements of one family might be arranged by the name of "Serial Order." Between two consecutive terms of the serial order, the isomorphism is more perfect than between any other two terms of the family.

From one term of the order to another there is a gradual modification of the chemical and physical properties, and these properties might, for the most part, be represented by functions really continuous with regard to limiting laws relative to isomorphous mixtures of which the properties are approximately the mean of the properties of their constituents.

In particular, two consecutive terms of the serial order are those of which the different isomorphous compounds are the most difficult to separate. It is this characteristic which, in a complex series such as that of the rare earths, admits of determining the serial order.

The solubility appears thus to be the fundamental characteristic which serves as a guide in the serialisation.

Just as a pencil of rays of different refrangibility can be dispersed by a prism, which classes them in a constant order whatever be the nature of the prism, so, in the same way, a mixture of isomorphous elements may be said to be "dispersed" by fractional crystallisation, which thus classifies the different terms in the order, generally constant, of the solubility of their salts, whatever be the nature of the salt chosen.

M. Locke has established a law of this order in connection with the alums and double sulphates of the magnesium series.

If, in a general way, the facts were presented with a like simplicity, there would exist a "law of the serial order," which would have long been enunciated, and which would play a useful part in chemistry. But, as a matter of fact, the order of the solubilities apparently differs for the types of different salts, and all that we can affirm is that very frequent coincidences exist.

These coincidences occur especially in the different terms of a natural family; they are less frequent in connection with the different terms of an isomorphous series which do not necessarily belong to the same natural family. Thus cerium, rubidium, potassium, and thallium form a group of isomorphous elements, but thallium cannot be considered as belonging to the natural family of the metals of the alkalis.

It is very remarkable that the group of the rare earths, the different terms of which are still so little known, should be the best studied from the special point of view with which we are occupied. Of all the natural families this contains

the greatest number of elements, the number being almost a quarter of the number of all the elements actually known.

The serialisation of the rare earths affords the highest interest, because there is ground for hoping that the relations attaching to the different terms of this series may be extended to other families of elements, and that finally there may be deduced from these laws a system of classification of the elements more coherent than that of Mendeleeff.

The total work on the rare earths permits of classing in the following order the best characterised terms of the series:—Lanthanum, cerium, praseodymium, neodymium, samarium, europium, gadolinium, γ-terbium, dysprosium, holmium, yttrium, erbium, thulium, ytterbium.

We do not make scandium appear in this list. We found it impossible to follow it in our fractionations, and we think our earths did not contain it. In addition to this, the little that is known about it leads to no analysis. It has been shown that in the group of rare earths, properly so called, the earths of low equivalent are the strong bases, and the earths of high equivalent are the weak bases.

The equivalent of scandium is lower than that of any one of the rare earths. Also the double potassium sulphate of scandium is insoluble in potassium sulphate, and this characteristic would allow of its being placed among the cerium earths.

If we consider that from lanthanum ($La = 138$) to terbium ($Tb > 163$) the atomic weights are constantly increasing, we feel some hesitation in inserting scandium ($Sc = 44$) among these elements. We think, therefore, that scandium belongs to some other series of elements, being allied either to thorium and uranium or to glucinum.

In order to justify the preceding serialisation of the rare earths, it is enough to recall the fact that most of the methods of separation allow of their being obtained successively in this order. This is the case with the double ammoniacal nitrates (Von Welsbach); also with the double nitrates of the magnesium series (Demarçay); also with the double alkaline sulphates (Lecoq de Boisbaudran); also the ethyl sulphates of the yttrium earths (G. Urbain).

The study of the other salts is still too incomplete for one to be able to affirm that the law is absolutely general; but we know of no fact, nor have we observed one, which formally contradicts it.

A certain number of cases exist in which it seems to break down, viz., when any one of the intermediate terms of the series appears at the head of the fractionations, as is the case with gadolinium when the simple nitrates with five molecules of water are fractionated (Demarçay).

It can be shown that this anomaly is only apparent. Let us fractionate thus the earths containing only lanthanum, cerium, praseodymium, neodymium, samarium, europium, and gadolinium. We shall obtain successively the nitrates in the inverse order to that in which we have just enumerated them.

The experiment was not done in this manner; but in the presence of yttrium earths one can successively observe their presence in this order from the beginning to the end of the fractionations.

The yttrium earths separate as simple nitrates in their normal order.

One of us made a great number of fractionations of these nitrates. They will be described in detail later on.

Thus, in this case, it is the existence in the series of a minimum solubility which seems to falsify the theory of the serial order, but it is obvious that this anomaly is only apparent. Several types of salts present similar minima. Thus we have proved the existence of a minimum corresponding to didymium in the series of the ethyl sulphates. Others exist for the acetates, oxalates, &c.

It would suffice that certain salts present at once a maximum or a minimum in the series in order to make the confusion of the solubilities appear complete, and to invalidate, to all appearance, the theory of the serial order.

These kinds of redoubling of the series upon itself may

be compared to the cases of anomalous dispersion, and to the cases of anomalous dilatation of certain liquids—such as water. The existence of the maximum density of water at 4° does not invalidate the general law of the expansion of liquids; the existence of anomalous solubilities should not similarly invalidate the law of the serial order. It is very evident, however, that such a law could only appear to advantage in a series such as that of the rare earths, the terms of which are very numerous.

In the families of ordinary elements which contain a very restricted number of terms, the preceding theory loses much of its interest.

The physico-chemical properties of the rare earths follow the law of the serial order very well.

From what is known of fractionations based on differences of basicity, it is manifest that any earth whatever presents, in general, a basicity intermediate between that of the term which precedes it and of the term which follows it in the serial order. Lanthanum oxide—first term of the series—is a very strong base. The basicity diminishes first with the terms following. It seems to pass through a minimum with the earths of terbium. It increases finally to a maximum with yttrium, then rapidly decreases in passing through erbium, thulium, and finally ytterbium—last term of the series—the oxide of which is a feeble base, the weakest of the group.

The atomic weights follow approximately, in the serial order, a law inverse to the basicity, the maximum corresponding to the terbium earths and the minimum to yttrium.

In the present state of our knowledge of the rare earths, the preceding theory can have no absolutely scientific accuracy; but we thought it our duty to expound it in this preliminary article, because it has been a remarkably sure guide to us in our researches, alone or together, on the separation of the rare earths for nearly ten years.

THE DETERMINATION OF CHROMIUM IN STEEL.

By F. IBBOTSON, B.Sc., and R. HOWDEN, B.Sc.

The usual volumetric methods for the determination of chromium in steel consist in the oxidation to chromic acid by means of a strong solution of potassium permanganate. This is added until, in the boiling solution, a permanent precipitate of manganese dioxide is obtained; the latter is then either filtered off or dissolved in hydrochloric acid. In the one case, the precipitate obstinately retains a small amount of chromium, which may, however, be washed out with sodium hydrate, and in the other case the expulsion of the chlorine is often troublesome. These inconveniences may be eliminated by using ammonium persulphate as the oxidant. Marshall made the observation that chromium salts are oxidised by persulphates alone, and found that the oxidation was accelerated by the addition of a silver salt (CHEMICAL NEWS, lxxxiii., 76), but the application of this to the determination of chromium in steel is attended with some difficulties, which we believe have stood in the way of the general acceptance of persulphates as suitable oxidising agents for the purpose.

When ammonium persulphate is added to a nitric acid solution of a steel, with or without the addition of a small quantity of silver nitrate, the manganese and chromium are speedily converted on warming to permanganic and chromic acids respectively. The oxidation is accompanied by a vigorous evolution of gas, due to the decomposition of the excess of persulphate. If the solution be boiled to effect complete decomposition, small amounts of the chromic and permanganic acids appear to be reduced again, the amounts depending, we think, to some extent on the degree of acidity of the solution. This reduction occasioned some trouble at first, but by operating in the manner described below, good results are obtained in much less time than the ordinary volumetric methods consume.

I. Steels Soluble in Nitric Acid (Specific Gravity 1.20).

The sample is dissolved in as small an amount of the acid as possible, and nitrous fumes expelled. After copious dilution, 2 or 3 grms. of solid ammonium persulphate are added together with a centigram. or so of silver nitrate, the addition of which is, however, unnecessary, provided that the solution is nearly neutral. The solution is heated until the evolution of gas commences, and allowed to stand at this temperature for a few minutes until the chromium and manganese are completely oxidised. When the amount of the latter metal is large, the oxidation to permanganate is quickly followed by a precipitation as dioxide, which must be filtered off, but in most cases there is no such precipitation. The solution is cooled, and a large excess of ammonium acetate added, after which sufficient lead acetate solution is added to precipitate the chromium as lead chromate. The precipitate is filtered through ignited asbestos, and after washing well with water containing a small quantity of pure ammonium acetate, is dissolved from the filter with nitric acid, sp. gr. 1.20. The solution is diluted freely, an excess of ferrous sulphate solution added, and the estimation completed by the use of N/20 potassium permanganate solution.

If a large excess of ammonium acetate is used, the lead chromate obtained is free from sulphate, and the nitric acid solution of the lead chromate readily lends itself to the gravimetric determination of either or both of the metals it contains.

Our experience of the process shows that the solution must not be too acid when the oxidation is being carried on. If large amounts of acid are present the oxidation fails, and the acid must be partially neutralised. In nearly neutral solutions complete oxidation can be effected in five minutes.

II. Steels not Soluble in Nitric Acid (Specific Gravity 1.20).

Steels containing large quantities of tungsten as well as chromium cannot be completely decomposed by nitric acid alone. To this class of material belong the modern high-speed cutting tool steels, which contain a trace only of manganese, and in many cases none at all. They are easily assayed for chromium in less than an hour's time by the following simple procedure:—

0.5 gm. of the drillings are treated with 10 c.c. dilute sulphuric acid (1:4), and the liquid briskly boiled to break up the sample. When decomposition is nearly complete, 2 c.c. of nitric acid (1:4) are added, nitrous fumes expelled, and luke-warm water added up to about 100 c.c. To this mixture, containing much of the tungsten as precipitated oxide, 20 c.c. of nitric acid (1:20), and 20 c.c. of silver nitrate solution (2 grms. per litre) are added, and then 2 or 3 grms. of ammonium persulphate. The mixture is then heated, and when the evolution of gas commences, the flask is vigorously shaken. The heating is continued with frequent shaking until the expulsion of gas is complete. It is then permissible to heat to boiling, and maintain in ebullition for a few seconds only. The liquid is then cooled, diluted, an excess of ferrous sulphate added, and the estimation completed as before by means of a standard solution of potassium permanganate.

The separated tungstic oxide does not seriously obscure the end of the reaction, but it can be removed by filtration if thought necessary. The removal of the silver at the same time by the addition of a few drops of hydrochloric acid leaves a filtrate ready for titration by means of ferrous solution and standard bichromate. Appended are three results from steels previously assayed by methods described by Brearley and one of us elsewhere.

Persulphate.			
A		5.86	5.87 per cent chromium
B		4.67	4.68 " "
C		2.90	2.95 " "

Sample C contained a small amount of manganese, which is included in the chromium result.

Rich chromiferous ferrotungstens can be just as readily assayed after opening out somewhat differently. These alloys are amenable to the attack of hydrofluoric and nitric acids, and when decomposition has been effected, an evaporation with the addition of a few drops of sulphuric acid provides a residue ready for the assay. An alloy, for example, containing more than 30 per cent of tungsten and 11.34 per cent of chromium yielded 11.35 per cent by this method, 0.25 grm. of the crushed sample being used.

University College, Sheffield

THE ELECTROLYSIS OF CYANIDES.

By ANDRÉ BROCHET and JOSEPH PETIT.

In a previous paper (*Bull. Soc. Chim.*, [3], 1904, vol. xxxi., p. 359) we showed that copper, zinc, and nickel dissolve in cyanide of potassium when we use them as electrodes in an alternating current circuit (frequency 42).

Iron and platinum behave in an identical manner, but contrary to the above mentioned metals they do not act, or at least not sensibly, on solutions of cyanide of potassium even when they are used as an anode. Thus it seemed to us to be indispensable to review and complete the work that has been already done on this subject.

Action of Iron on Cyanide of Potassium.—Classic works state that iron dissolves in cyanide of potassium. This reaction is absolutely insignificant; iron in the form of strips, nails, pianoforte wires, &c., placed in a hot or cold solution of cyanide of potassium at 4 grm.-molecules per litre, gives off an extremely small quantity of hydrogen, and after a certain time we are able to detect the presence of traces of ferrocyanide of potassium, thanks to the great sensitiveness of its reactions.

If the iron is placed in contact with a strip of platinum, the gas then produced on this strip becomes a little more evident. The reaction is not much more distinct with pyrophoric iron.

Electrolysis of Cyanide of Potassium.—In a paper on the oxidation of chloride of potassium under the influence of electrolysis, Kolb (*Ann. der Chemie und Physik.*, 1847, vol. xiv., p. 236) stated that cyanide of potassium was transformed into cyanate. This assertion has never been confirmed. On the other hand, Schlagdenhauffen (*Journ. de Ph. et de Ch.*, [3], 1863, vol. xlv., p. 100) and Luckow (*Dingl. Polyt. Journ.*, vol. ccxxxix., p. 805) have shown that there was nothing formed but potash, ammonia, and carbonic acid. Further, the formation of cyanate is very unlikely on account of its instability in aqueous solution.

As we have already stated, the platinum electrodes are not attacked.

Gore observed that iron used as an anode dissolves if the current is strong, and remains unattacked if the current is weak; but the amount of solution in all these cases is absolutely insignificant. Thus, with an iron wire of 8 square centimetres of surface, and with an intensity of current of 4 ampères, that is to say 50 ampères per square decimetre, the loss of weight after four hours was 0.018 grm., or about 1 m.grm. per ampère-hour.

If we make use of a diaphragm the attack on the metal is a little stronger; with 12 ampères per square decimetre, we found a loss of 5 m.grms. per ampère-hour, and 30 m.grms. with 30 ampères per square decimetre.

Thus it is well established that iron has only a negligible action on cyanide of potassium when used as an anode.

Electrolysis of Ferro- and Ferricyanides.—We know that the electrolysis of ferrocyanide of potassium with electrodes of platinum gives ferricyanide at the anode with a more or less considerable return; inversely, ferricyanide gives ferrocyanide at the cathode, with the formation of a blue deposit at the anode.

With electrodes of iron, this metal takes part in the reaction, and in both cases gives a variety of Prussian blue

at the anode, but only if we use a diaphragm; otherwise the alkali formed at the cathode decomposes this blue deposit, giving hydrate of iron.

Without a diaphragm we arrive at a state of variable equilibrium according to the conditions of the experiment. The same takes place with an alternating current, as we shall see later on, but in this case it is necessary to use an extremely high density of current.—*Bull. Soc. Chim.*, Series 3, vol. xxxi., No. 12.

HYDRONITRIC ACID AND THE INORGANIC TRINITRIDES.*

By I. M. DENNIS and A. W. BROWNE.

(Concluded from p. 313).

SUMMARY (continued).

C.—A Method for the Detection of Hydronitric Acid and the Inorganic Trinitrides.

In 1898 Curtius and Rissom (*Journ. Prakt. Chem.*, [2], lviii., 261) called attention to the deep red colouration produced either indirectly by shaking in air a solution of ferrous ammonium sulphate which had been treated with sodium trinitride, or directly by treating a ferric chloride solution with the same substance. From the red solution, boiling caused the precipitation of all of the iron as ferric hydroxide, and caused the red colour entirely to disappear. Even in the cold they found the colour faded gradually, and that a precipitate containing a basic ferric trinitride appeared. In a parenthetical clause they suggested that the production of this red colour was a "charakteristische Reaktion auf Stickstoffwasserstoff und auf Eisenoxydsalze."

In 1900 Curtius and Darapsky (*Journ. Prakt. Chem.*, [2], li., 408) again commented upon the blood-red colouration, produced this time by the action of sodium trinitride upon ferric ammonium sulphate in sufficiently strong solution. The coloured solution they again found to deposit a brown basic ferric trinitride, that appeared at once, if the solution was dilute, but only after some time if it was concentrated.

It has been found, on experimenting with the substances in this laboratory, that by observing the simple precaution of keeping the ferric compound in excess, the red colouration produced by the action of hydronitric acid or an inorganic trinitride will last indefinitely, even in very dilute solutions. If, for example, a ferric chloride solution of any desired strength is treated with hydronitric acid or the solution of a trinitride (also of any desired strength) up to the point only where the brown precipitate at first formed is re-dissolved when the solution is shaken up, then the colouration produced will last for weeks. The colour may vary, according to the strength of the solutions used, from a light reddish brown to a blood-red colour so deep that the solution, even in thin layers, appears almost black. In very concentrated solutions the odour of hydronitric acid may be perceived.

The action of an excess of the ferric salt in preventing the spontaneous precipitation of ferric hydroxide or a basic ferric trinitride from a solution of ferric trinitride is probably to be explained on the ground that the precipitation occurs as the result of hydrolysis, and that this is prevented by the addition of a salt with a common ion, which forces back the dissociation of the ferric trinitride.

This characteristic behaviour of a ferric salt toward the trinitrides has been of considerable use in this laboratory in testing residues and old solutions for hydronitric acid. It would also be of value in experimental work upon new methods of preparing the acid. In order to insure the perfect reliability of the test, a study has been made of some of the properties, physical and chemical, of the solution of ferric trinitride.

* From the *Journal of the American Chemical Society*, NXXI., No. 6.

The colour of the solution is remarkably similar to that of a solution of ferric sulphocyanate. When the colour intensity of the two is about the same, the eye, even with the aid of the spectroscope, can find no difference between them. The colour intensity of both solutions rapidly diminishes on dilution with water, that of the ferric sulphocyanate, however, fading more rapidly than the colour due to the ferric trinitride, as was ascertained by a series of careful experiments conducted with a Duboscq colorimeter. These facts may be readily explained on the assumption that the colour is in each case characteristic of the undissociated compound. Increasing the dilution would then not merely distribute the coloured bodies throughout a greater space, but would also, by increasing the dissociation, diminish their total number. Thus, diluting a given solution with its own volume of water would reduce the colour to less than one-half its former intensity. Moreover, since sulphocyanic acid is a much stronger acid than hydronitric, its salts will be dissociated to a greater extent for a given concentration (*Ann. Prakt. Chem.*, [2], 1885, xxxii., 300). Therefore dilution of a given solution of ferric sulphocyanate should cause a greater loss of colour than similar dilution of a solution of ferric trinitride of the same concentration.

Concerning the sensitiveness of the ferric chloride test for trinitrides, it may be said that if one part by weight of N_3 be present in 100,000 parts of water, the addition of a little ferric chloride solution, insufficient in itself to produce any perceptible colouration, will, by the formation of ferric trinitride, produce a quite distinct colour, which may be clearly seen by looking down through the test-tube at a white background. Of course in dealing with such weak solutions it is necessary to take care not to mistake the colour of the ferric chloride solution itself for that of the trinitride. The danger may easily be avoided by adding the same amount of ferric chloride solution as that used in the test, to a volume of water equal to that of the solution to be tested.

With respect to the general applicability of the test it may be said that many representative inorganic trinitrides have been tested, including the potassium, sodium, barium, calcium, strontium, mercuric, cadmium, nickel, &c., as well as even the comparatively insoluble lead, silver, and mercurous compounds. In every case the characteristic red colouration has been quickly produced. Even in pyridine solution dry silver trinitride and ferric chloride act in the same way.

Dilute mineral acids (preferably hydrochloric acid), discharge the colour of ferric trinitride, but do not materially affect the colour of ferric sulphocyanate. On the other hand, mercuric chloride discharges the colour of ferric sulphocyanate more readily than it does that of ferric trinitride. By the aid of these reactions sulphocyanates and trinitrides may be identified even when both are present.

D.—The Reaction between Hydronitric Acid and Potassium Permanganate in the presence of Sulphuric Acid.

It seemed reasonable to suppose that hydronitric acid might be quantitatively determined by titration with potassium permanganate, and that the reaction would proceed according to the following equation:—

Preliminary experiments showed, however, that the amount of permanganate necessary for the oxidation of the hydronitric acid was considerably higher than that called for in the above equation, and the experiments described in this chapter were undertaken with a view to ascertaining the exact nature of the reaction.

The attempt was first made to determine the ratio between hydronitric acid and potassium permanganate in presence of sulphuric acid by ordinary methods of titration. An approximately tenth-normal solution of potassium permanganate was accordingly standardised with ammonium

ferrous sulphate. A dilute solution of hydronitric acid was standardised by precipitation of measured volumes with silver nitrate, evaporation of the washed precipitate with hydrochloric acid, and weighing as silver chloride.

Titrations were made by the following methods. (In each case sulphuric acid was added in sufficient quantity to keep the solution quite strongly acid throughout the experiment). 1. By adding a measured amount of hydronitric acid to a measured excess of potassium permanganate, (a) at room temperature (20°), and (b) at a temperature of 45°. The excess of permanganate was subsequently determined by back titration with standard ammonium ferrous sulphate solution. 2. By gradually adding hydronitric acid to a measured amount of permanganate until the colour was just destroyed. 3. By adding hydronitric acid in slight excess to a measured amount of permanganate and then adding more permanganate, drop by drop, until the faintest discernible permanent colouration was produced. In each case the reaction took place only after the lapse of several minutes. Raising the temperature hastened the reaction to some extent, and apparently had no other effect. At temperatures much above that of the room it was considered advisable to keep the reacting substances in a stoppered flask provided with a U-tube containing silver nitrate solution, in order to detect any loss of hydronitric acid during the titration. No loss was found to have occurred in any of the experiments. The results of the titrations are given in Table V.

TABLE V.

Number of experiment.	Number of different titrations made.	Ratio of molecules of HN_3 to one molecule of $KMnO_4$.	
		Extremes.	Average.
1a	5	2'12—2'22	2'18
1b	6	2'10—2'29	2'21
2	10	2'11—2'39	2'25
3	5	2'40—2'60	2'47
Average from the twenty-six titrations, 2'27			

From the foregoing results it will be seen that this method of ascertaining the ratio between the two reacting substances is rather unsatisfactory. Both the variations within a given series of titrations, and the variations of the averages of different series, seem to be outside the limits of experimental error. The difficulty is no doubt due to the impossibility of securing a definite end-point, owing to the extreme slowness of the reaction toward the end of the titration. It is probably also due, in some degree, to a tendency on the part of the reacting substances to unite in different proportions under different conditions, as when, for example, one or the other may temporarily or locally be in excess during the titration. Further reason for this view will be seen later. The method employed in the first experiment was found to be doubly unreliable because of the fact that when hydronitric acid is added to potassium permanganate in excess, there are thrown down oxides of manganese of varying composition which are insoluble alike in sulphuric and hydronitric acids. (This is true even when there is a considerable excess of sulphuric acid present in the solution during the titration).

The titration experiments were now discontinued, and a qualitative study made of the reaction products formed. The solution, obtained by allowing a slight excess of hydronitric acid to act upon a quantity of potassium permanganate solution in the presence of sulphuric acid, and then destroying the excess of hydronitric acid by adding permanganate drop by drop until the characteristic colour was just discernible, was examined as follows. It was not considered necessary to look for free N_3 among the reaction products, for it does not seem reasonable to suppose, with Dennstedt and Göhlich (*Chem. Zeitung*, xli., 876), that the monovalent nitrene group, similar in so many respects to the chlorine atom, could exist alone, even if the hydrogen atom could be removed from hydronitric acid without breaking it up. There would probably

be immediate union of two such groups, as suggested by other investigators (Curtius, Hantzsch, and others), to form a compound, $(N_3)_2$, which we have called nitrine, analogous to the chlorine molecule. It was, however, theoretically possible that, during the oxidation of the hydronitric acid, certain oxyacids might have been formed, analogous to the oxyacids of chlorine. To show the analogy the following list is given:—

In these compounds the nitrine group would show, according as none, one, two, or three of its nitrogen atoms became pentavalent, a monovalent, trivalent, pentavalent, or heptavalent character, just as the chlorine atom is supposed to do.

To ascertain whether any such nitrogen acids were formed by the action of permanganate upon hydronitric acid, portions of the solution whose preparation was described in the first lines of the preceding paragraph were carefully distilled (a) at temperatures of 70° and 100°, respectively, at ordinary atmospheric pressure, and (b) at temperatures of 50° and 80°, respectively, at a pressure corresponding to 10 c.m. of mercury. The vapours were in each case led into water containing a little phenolphthalein with just barely enough sodium hydroxide to render it. In no case was the red colour destroyed. The absence of nitric acid was still further established by the fact that the test with ferrous sulphate solution and concentrated sulphuric acid repeatedly gave negative results.

To show that none of the nitrogen had been changed to ammonia, or to some other nitrogen base, with consequent formation of ammonium sulphate or a sulphate of the base, a part of the solution was distilled with calcium hydroxide. The distillate gave no alkaline reaction.

From the foregoing experiments it was a legitimate inference that the hydrogen of the hydronitric acid had gone to form water, and that the nitrogen had been given off as gas, either as free nitrogen, or one of its non-acid-forming oxides.

During the titration experiments, described above, it had been observed that minute bubbles of the gas were slowly evolved as the decolorisation took place. These were at first thought to be bubbles of hydronitric acid escaping from the solution as the result of the action of the sulphuric acid, until the use of stoppered flasks with U-tubes, containing silver nitrate solution, proved the contrary. Shaking the flask during the progress of the reaction, even after decolorisation was complete, caused a comparatively brisk evolution of gas to take place.

The composition of the gas was determined qualitatively by collecting a quantity in a Hempel pipette, and treating it successively with the following series of reagents: Alcohol, water, caustic potash, alkaline pyrogallol, fuming sulphuric acid, and cuprous chloride. Contraction took place only after passing it through the alkaline pyrogallol. This indicated the presence of oxygen. The residues

obtained by treating in this way gases evolved from reacting mixtures (of HN_3 , $KMnO_4$, H_2SO_4) in which either the hydronitric acid or the potassium permanganate, respectively, was present in excess, showed no change in volume when mixed with either equal or double volumes of hydrogen, and subjected to the action of the electric spark in a Hempel explosion pipette. This showed quite conclusively that no oxides of nitrogen were present, a fact that already had seemed probable from the circumstance that no contraction had occurred in any case when the gas had been passed through alcohol or water. The residue, then, consisted of nitrogen.

To ascertain the quantitative composition of the gas under different conditions (*i.e.*, according as one or the other of the reacting substances was present in excess in the mixture from which the gas was evolved), portions were simply shaken with alkaline pyrogallol, and the volume measured before and after the operation.

It was found, in general, that when the permanganate was present in excess the percentage of oxygen in the gas mixtures evolved was not very constant. The insoluble higher oxide of manganese that appears under these conditions is, therefore, in all probability, of variable composition. While the results of a series of four experiments in which the permanganate was taken in excess, vary in a way that seems to indicate that the ratio between the amounts of hydronitric acid and potassium permanganate entering into the reaction in different cases is not a constant one under these conditions, still the data accord fairly well with the amounts indicated in the equation—

This equation is not far from agreement with the results of titration given in Table V. under the heads 1a and 1b. These results were also obtained with permanganate in excess.

When hydronitric acid was taken in excess, the results were more satisfactory. A series of experiments were made to determine the ratio of nitrogen evolved to permanganate reduced, when hydronitric acid was in excess. The composition of the gas evolved was found to be 92 per cent nitrogen (by volume) and 8 per cent oxygen. Knorre and Arndt (*Ber.*, 1900, xxxiii., 30), in somewhat similar work on the oxidation of hydroxylamine by various agents, devised a special form of apparatus to serve the double purpose of measuring the gas evolved and preserving it free from air or other gases for subsequent analysis. In our work, however, this was not necessary, as the gas mixture, evolved under certain conditions in a Hempel pipette, was analysed separately, without making any effort to measure the total volume. The total volume of gas evolved from a measured amount of the same reacting mixture, under similar conditions, was then measured in an ordinary Lunge nitrometer. To ascertain the amount of nitrogen evolved, the volume of oxygen, calculated from the results of analysis, was subtracted from the total volume. In using the nitrometer care was taken to immerse the evolution bottle in a constant temperature bath before each reading. During the reaction the bottle was frequently shaken to facilitate evolution of the gas. To test whether any appreciable quantity of the gases remained in solution, additional experiments were performed, in which a small Erlenmeyer flask was substituted for the evolution bottle. One of the reacting substances was placed in the flask, and the other in a small test-tube standing upright within the flask. By inclining the flask, the two solutions were mixed. After the reaction was complete, the solution was heated nearly to boiling, and then permitted to cool down to the initial temperature. The volume of gas evolved was not appreciably greater than when the evolution bottle was used and the solution not boiled. Therefore no appreciable amount of gas had remained in solution.

In Table VI. are given the results of a series of experiments showing the ratio, as obtained above, between

nitrogen evolved and permanganate reduced when hydronitric acid is in excess.

TABLE VI.

Number of experiment.	Cubic centimetres KMnO_4 taken.	Cubic centimetres gas evolved.	Cubic centimetres nitrogen evolved.	Molecules N_2 per molecule KMnO_4 .
1	24.6	24.7	22.7	4.54
2	25.0	25.1	23.1	4.56
3	24.5	24.7	22.7	4.56
4	24.7	24.1	22.2	4.44
5	22.4	22.2	20.4	4.49
6	20.2	20.1	18.5	4.51
Average.				4.52

From these results it will be seen that when hydronitric acid is in excess the ratio potassium permanganate to hydronitric acid is smaller than when the permanganate is in excess; that is, in the former case a given amount of permanganate will act upon more hydronitric acid than in the latter case. This conclusion is also indicated in a rough way by the results given in Table V., where we find the ratio to have smaller values when potassium permanganate is in excess than when equivalent amounts are taken, or when hydronitric acid is virtually in excess. The following equation best represents the results given in Table VI. :—

To obtain a further check upon this equation the ratio between potassium permanganate and hydronitric acid (the latter in excess) was determined by adding a measured amount of a standardised solution of the former to a measured excess of the latter, and determining the excess of hydronitric acid by precipitation with silver nitrate in the usual way, after the reaction had taken place. The results of the two experiments performed are given in Table VII.

TABLE VII.

Number of experiment.	Cubic centimetres KMnO_4 taken.	Cubic centimetres HN_3 taken.	Cubic centimetres HN_3 oxidised.	Molecules HN_3 per molecule KMnO_4 .
1	24.6	49.0	17.2	3.08
2	25.0	48.8	16.7	2.94
Average.				3.01

These results show close agreement with those given in Table VI., and point toward the same equation. Moreover, by combining the results of Table VI. and VII. it may be proved that under the conditions of the experiments no polymeric nitrogen is evolved, for if 1 molecule of permanganate oxidises 3 molecules of hydronitric acid, as indicated by Table VII., causing the evolution of 4.5 molecules of nitrogen gas, as indicated in Table VI., then for each molecule of hydronitric acid oxidised there are produced 1.5 molecules of nitrogen. Hence all the nitrogen of the acid appears as diatomic nitrogen. A density determination made according to the method of Dumas confirmed this conclusion.

Only one experimental fact is not in close accord with the above equation. Upon inspection of the equation it will be seen that in the mixture of gases evolved during the progress of the reaction there should be 10 per cent (by volume) of oxygen and 90 per cent of nitrogen. Experimentally, however, the mixture was found to contain about 8 per cent of oxygen and 92 of nitrogen. No explanation of the error has been found, but it is not to be considered as sufficiently serious to cast doubt upon the validity of the equation as given above.

It is apparent from the results of these experiments upon the reaction between hydronitric acid and potassium permanganate that the latter agent can not be used for the accurate quantitative determination of the acid. The results are of theoretical interest, however, because of the light that they appear to throw upon the structure of potassium permanganate, a subject that will be discussed by the authors in a later paper.

ELECTROLYTIC PREPARATION OF TIN PASTE.*

By F. GELSHARP.

TIN paste is used for the production of metallic or silvered paper, having the appearance of tin or lead foil, and it is also used for ornamental purposes.

As I believe members are interested in any process in which electro-chemistry advantageously takes the place of the older chemical methods, I beg to bring before the Faraday Society the following description of a process for manufacturing tin paste which was specially designed for a firm of paper makers.

The oldest method of making tin paste was that carried out by the natives of India. They melted block tin at a high temperature, and poured it into a wooden box, which was then shaken vigorously; the tin was thus converted into very fine shot and dust. The finer particles which they used for the paste were separated from the coarser granules by gravitation by means of water. It was afterwards dried and mixed with a weak solution of glue, and in this state it was ready for use. This they used as a paint, the article to be ornamented was coated with it, and after being dried it was burnished.

The chemical process for making tin paste as generally carried out in this country is as follows :—The commercial ingot is reduced to what is known as feather tin by melting it and then allowing it to fall some distance. The tin in this form is dissolved in strong hydrochloric acid, with the aid of heat, in copper vessels, and a concentrated solution of stannous chloride thus obtained. The liquid is diluted and the tin precipitated in the form of paste by introducing metallic zinc. The process is troublesome on account of fumes, and, moreover, does not give the whole of the precipitated tin in the form of paste, but partly as bright metallic feathers and crystals, which have to be worked over again; whereas in working the electrolytic process about to be described there are no fumes, and the paste is perfect in every respect. Further, the process is not so costly, and can be worked continuously, the deposited paste being removed at intervals without stopping the current.

The electrolytic process is similar to the electro-refining of metals. Anodes of tin are dissolved in an electrolyte of dilute hydrochloric acid, and the tin is deposited in the form of a sponge or paste on cathodes of the same metal. The spongy deposit is lighter than the electrolyte on account of the hydrogen it contains, and consequently floats on the surface of the solution after being detached from the face of the cathodes, so that it can be conveniently removed without breaking the current.

An apparatus capable of producing 20 cwt. of tin paste per week consists of a generating plant giving 1500 amperes at 8 to 10 volts. There are five vats, which are worked in series, and are made of slate or pitch-pine wood 106 × 106 × 91.5 c.m. deep (3 ft. 6 in. × 3 ft. 6 in. × 3 ft. deep), each containing four anodes and five cathodes coupled in parallel.

The anode plates are about 2.5 c.m. (one inch) thick, roughly cast from commercial ingots of tin; the surface exposed to the electrolyte being 91.5 × 76 c.m. (3 ft. × 2 ft. 6 in.).

The cathode plates are of block tin or tinned iron, the active surface being 91.5 × 76 c.m. (3 ft. × 2 ft. 6 in.).

The anodes are supported at the two top corners, and in each vat are all connected to one conductor.

The cathodes are supported by and soldered to copper conductors, which are all connected to a main conductor. These main conductors are of circular copper bars 3.2 c.m. (1.4 in.) in diameter.

The electrolyte is a dilute solution of hydrochloric acid in 5° Tw., which must be free from arsenic.

The current density is 270 amperes per square metre, or 25 amperes per square foot of cathode surface.

As the anodes are dissolved away they are removed before they crumble and fall to pieces, and what remains

* A Paper read before the Faraday Society, December 19, 1904.

of them is melted up with fresh ingots and cast, to form new anodes.

The electrolyte is kept in circulation by means of a small turbine or plunger pump of lead or block tin driven by a small motor; the liquid is drawn from the bottom of the vats, and discharged into the top; this is found necessary, as otherwise the electrolyte at the bottom of the vats would soon become very rich in tin, and instead of tin paste at the lower parts of the cathodes there would be crystal or leaf tin deposited.

When the deposited tin sponge has grown to about an inch in thickness it is detached from the cathodes by means of a T-shaped scraper, which is pushed down the face of the cathode plates; the floating spongy tin is removed from the surface of the vat by means of a perforated scoop to prevent short-circuiting of the current through the floating tin; the cathode plates are varnished or painted with a non-conducting material from 5 to 7.5 c.m. (2 or 3 inches) below the surface line. The tin paste is allowed to drain, and is then thoroughly washed with water, and dried to make it ready for use.

This may not seem to be an efficient way of utilising the electric current, because the current-efficiency is only about 50 per cent; but any attempt that I have made to produce tin in the form of paste or sponge at a higher efficiency has been futile; it appears to be necessary to have hydrogen deposited along with the tin, for when no hydrogen is deposited the tin comes down in a crystalline or bright leaf-like form.

A METHOD FOR THE DETERMINATION OF CHLORIC ACID.

By W. S. HENDRIXSON.

In the methods for the determination of chloric acid by reduction, metallic zinc, in some form, and ferrous sulphate have been the reducing agents most used, though several others, including sulphur dioxide and formic aldehyde, have been employed. The conditions under which zinc and ferrous sulphate have been used have been much varied. Thorpe (*Journ. Chem. Soc.*, xi., 541) and Thorpe and Eccles (*Journ. Chem. Soc.*, xiv., 856) used the zinc-copper couple to reduce chlorates, and determined the chloride, resulting from the chlorate, with a solution of silver. Bothamley and Thompson showed that the results by this method were too low unless sulphuric acid was added near the end of the reduction to dissolve any basic salts of zinc (*Journ. Chem. Soc.*, liii., 164). By the same method, Becker also found the results too low, and preferred to use zinc dust and a little copper sulphate (*Repert. Anal. Chem.*, i., 377). Fleissner used zinc dust and boiled the solution one hour (*Zeit. Anal. Chem.*, xx., 115), but Becker attained complete reduction only by using a large excess of zinc dust with sufficient sulphuric acid to dissolve it completely without the aid of heat.

Stelling reduced chlorates by long boiling with ferrous sulphate, in alkaline solution, and determined the resulting chloride (*Zeit. Anal. Chem.*, vi., 32). Becker found that the reaction was very slow and incomplete, and recommended a neutral solution of ferrous sulphate. Carno reduced the chlorates in bleaching powder by heating at 100° with a large excess of ammonium ferrous sulphate and an excess of sulphuric acid (*Comptes Rendus*, cxxiii., 449). The amount of chlorate was found either by titrating the resulting chloride by the method of Volhard, or by determining the excess of ferrous sulphate with permanganate. Rosenbaum states that chlorine will be lost in this method of reduction if the acid and the ferrous sulphate are added to a hot solution of the chlorate (*Zeit. Angew. Chem.*, 1893, 80).

In the course of my work on the action of chloric acid on metals, it was observed that metallic iron very readily reduces free chloric acid even in very dilute solutions

(*Journ. Am. Chem. Soc.*, xxvi., 747). At ordinary room temperature the solution of the metal is very rapid in moderately concentrated solutions of the acid, and the iron goes at once into the ferric condition, as was proved by many tests while solution was going on. No gas is evolved, but the iron simply disappears, and there results the yellowish-brown solution of ferric salt, and the solution remains clear if the acid is in considerable excess. Whether iron alone thus reduces chloric acid completely could not be determined with accuracy, owing to the fact that toward the end of the reaction large amounts of oxide and possibly basic salt are necessarily formed, and these make it impracticable to obtain a solution suitable for titration with silver without the use of agents which would also decompose chloric acid. An approximation, however, showed that at least 95 per cent of the chloric acid was reduced. These facts suggested that the determination of chloric acid might be brought to a very simple form by using metallic iron as the chief reducing agent in the presence of an excess of sulphuric acid, which would prevent the formation of insoluble compounds, make the method applicable to chlorates by setting free the chloric acid, and form ferrous sulphate, which is itself a reducing agent for chloric acid, and which would already be present to serve, when oxidised, as the indicator in the titration of the chloride formed, by the method of Volhard. It is evident, therefore, that such a method would be a very simple combination of the two general methods already mentioned, the reduction of chloric acid by a metal, and probably a more efficient one than zinc, and the reduction by ferrous sulphate.

To carry out the method a weighed amount of pure potassium chlorate or a measured volume of chloric acid of known strength was placed in a small flask with about 50 c.c. of pure sulphuric acid having a concentration of about 10 per cent, and an excess of "card-teeth" used in most laboratories as a convenient form of iron. In some of the experiments recorded below, the flask was fitted with a delivery-tube which dipped into water, the purpose being to prevent the possible loss of hydrochloric acid, a precaution which at room temperature was proved to be wholly unnecessary. At first ferric salt is formed, and gives the solution the characteristic colour due to ferric salts, but the salt is soon reduced and the solution becomes colourless or slightly green. If all the chlorate is dissolved at the beginning of the experiment, the disappearance of the yellow colour may be taken to mark the end of the reduction, which requires, at room temperature, about one hour. No doubt the reduction could be hastened by heating, if precaution were taken to prevent the loss of hydrochloric acid by volatilisation. As might naturally be expected, the method serves quite as well for bromic acid and bromates as for chloric acid and chlorates, and two determinations of the bromic acid in potassium bromate are given below.

After the reduction was completed the solution was made up to a definite volume, and portions of it were titrated with N/20 silver nitrate by Volhard's method. Usually an excess of silver was added before the iron was oxidised with an excess of nitric acid to the ferric condition to serve as the indicator. There seems, however, to be little danger of the loss of chlorine if the nitric acid is added before the silver.

The following are results obtained by the method described, the amounts of silver required in the titrations being calculated to chloric acid or bromic acid:—

1. 5 c.c. of a solution of chloric acid gave 1.0639 grms. HClO_3 .
2. 5 c.c. of the same solution gave 1.0619 grms. HClO_3 . The same solution, titrated with standard barium hydroxide, gave, in 5 c.c., 1.0665 grms. HClO_3 .
3. 0.4595 grm. KClO_3 gave 0.3158 grm. HClO_3 ; calculated, 0.3165 grm.
4. 0.6709 grm. KClO_3 gave 0.4628 grm. HClO_3 ; calculated, 0.4622 grm.
5. 0.8300 grm. KClO_3 gave 0.5731 grm. HClO_3 ; calculated, 0.5718 grm.

6. 1.2744 grms. KClO_3 gave 0.8778 grm. HClO_3 ; calculated, 0.8778 grm.
 7. 0.3350 grm. KBrO_3 gave 0.2605 grm. HBrO_3 ; calculated, 0.2585 grm.
 8. 1.0983 grms. KBrO_3 gave 0.8460 grm. HBrO_3 ; calculated, 0.8478 grm.

The method above described seems to have some advantages. It is extremely simple. It can be carried out at room temperature, avoiding any danger of the loss of hydrochloric acid by heating. In the reduction and the preparation of the solution for titration are necessary only iron and pure sulphuric and nitric acids, which are always at hand in every laboratory, and no filtering or other operations likely to occasion loss of chlorine or loss of time are required.

Perchloric acid shows the same indifference toward metallic iron as toward most other reducing agents, and does not therefore interfere in the determination of chloric acid by this method.—*American Chemical Journal*, xxxii., No. 3.

A RAPID METHOD FOR THE DETERMINATION OF TOTAL SULPHUR IN IRON BY EVOLUTION.

By S. S. KNIGHT.

THE recent modification of the method for determining sulphur in iron, presented by Walters and Miller, of Pittsburgh, Pennsylvania, had as its principal disadvantages the extraordinarily long time, which they claim would be at least an hour, under the most favourable circumstances, to complete a sulphur determination, and also the expensive and unusual apparatus for roasting samples in a current of reducing gases.

In commercial laboratories which are not equipped with this apparatus, the recent modification of this roasting process has consisted in roasting the weighed sample for a period of one hour at a slowly increasing temperature. The culmination of this annealing process was the highest heat obtainable before a blast-lamp, which was continued for at least fifteen minutes. The sample thus roasted was treated as heretofore by the evolution process.

In the laboratory of the Birmingham Pipe and Casting Company, the writer has been able to get results which check very closely with those obtained by the above-described method, and also with those obtained by the barium chloride gravimetric method, by the following process:—

The weighed sample, which in our case consisted of 2 grms., was mixed with 1 grm. of the purest obtainable iron dust by hydrogen, and in which the sulphur content had been previously determined. This mixed sample is then placed in a small porcelain crucible and 1 grm. more of the iron by hydrogen is sprinkled over the top so as to form a continuous covering. On top of this is placed a small disc of quantitative filter-paper, the lid is then placed on the crucible, and this is placed on the triangle over the blast-lamp. For ten minutes the highest heat obtainable with the blast-lamp is used in roasting this mixture, at the expiration of which time it is allowed to partially cool, and the contents of the crucible are then placed in the ordinary evolution-flask and treated with hydrochloric acid, while the evolved gases are washed in any of the common forms of absorption bulbs. The absorbent liquid in our case has been an ammoniacal solution of cadmium chloride, which was afterwards titrated with the iodine solution of known strength. The results obtained by this method are exactly those given by standard gravimetric methods and also the same as those obtained by Walters and Miller's method, while the time consumed is something less than one-half hour from the time the sample arrives in the laboratory.

It is believed by the writer that the advantage of this

modification will be readily appreciated by chemists in charge of commercial laboratories.—*American Chemical Journal*, xxxii., No. 1.

NOTICES OF BOOKS

A Chemical Conception of the Ether. By Professor D. MENDELEEF. London: Longmans, Green, and Co. Pp. 51.

As is well known, Prof. Mendeleef has classified the known elements into groups and series in accordance with their atomic weight and chemical properties. Following out this classification he endeavours to show that two of the places in his "zero" group may be assigned to coronium and ether, both of which would have atomic weights much less than hydrogen, and, in consequence of their great molecular velocity, could not exist on the earth, though they might on the sun and the more massive stars, or even, in the case of ether, be too volatile to be retained by any known star. Be it noted that this is merely a speculation, and we have deliberately used the permissive phrase "may be," as we do not gather that the author would "father" any more definite expression. We see no reason why there should not be many elements in series "o" and possibly "o o" of less atomic weight than hydrogen—elements which could not exist in a free state on the earth, and possibly coronium does represent one or more of those elements; but as regards ether, our speculation has led us in a different direction; we consider ultimate matter to consist of at least two—possibly more—infinately rigid, absolutely elastic substances of different masses; of these ether is the least massive, and is not subject to gravity, being itself the cause of gravity; that is to say, gravity is the resultant of its blows on the more massive substance or substances; whilst ponderable matter consists of the more massive substance or substances. Here we are more in accord with Lord Kelvin than the author, for the latter considers all matter to be subject to gravity, whereas the former does not, though we should not care to claim any close approximation in the details of our respective conceptions of the ultimate constitution of matter.

At present all such speculations are speculations pure and simple, nor do we see any likelihood of subjecting any of them to physical tests.

What is the essential condition that an atom "A" will combine with an atom "B" when "C" is absent, whereas the addition of "C" will separate "A" from "B" and form a combination of "A" and "C"—all these retaining their individuality throughout? We do not know; and until we do know, we cannot say whether a purely kinematical conception of matter is satisfactory.

Food Inspection and Analysis. By ALBERT E. LEACH, S.B. New York: John Wiley and Sons. London: Chapman and Hall, Ltd. 1904.

THE student of dietetics, as well as the public analyst, will have much reason to be grateful to the author of this work for the admirable treatise he has produced. Besides containing the details of the most satisfactory methods of determining the constituents of almost every variety of food material and detecting common adulterations, it includes much information concerning the values of different kinds of foods which is not as a rule to be found in text-books of food analysis, and which will be no doubt specially appreciated by the food economist. Thus the composition of flesh foods and eggs are fully discussed, numerous tables being given to show the proportions of the constituents of various kinds of meats and meat preparations; directions are given for the detection of horse flesh when mixed with other meats, and also hints for discriminating between frozen and fresh meat. The

work compares most favourably both in choice of material and in treatment with other similar text-books, and it possesses the great attraction of presenting its information in a very concise form, unnecessary matter, such as the discussion of superseded methods, or of modifications of existing methods, which have not yet been thoroughly tested, being rigidly excluded. At the same time the short descriptions of manufacturing processes for the preparation of various food materials are well worth the space allotted to them, as being likely to indicate probable and possible impurities. A chapter is devoted to colouring matters in general, and another to preservatives, and it is suggested that in all cases in which adulterations are found the analyst should determine—at any rate, approximately—the amount present, so that determination as well as detection methods are always included. The photomicrographs form a very characteristic feature of the book. They include, firstly, illustrations of powdered food and food products, and also powdered adulterants; secondly, typical adulterated foods, which will be found most useful; and thirdly, sections of foods and adulterants. By careful study of these plates and the preparation of similar slides, the student should be able to make himself familiar with the appearance of the more common substances under the microscope, the use of which in food analysis is rightly strongly advocated. The author having had experience in one of the best food laboratories existing, has undoubtedly had unique opportunities of estimating the various advantages offered by one method over another, and has evidently thoroughly tested the various methods in use, so that when he shows a decided preference for any modification—as, for example, in the determination of the total solids in milk—it may be confidently assumed that there is a good deal to be said for his view.

A Select Bibliography of Chemistry, 1492—1902. Second Supplement. By HENRY CARRINGTON BOLLON. City of Washington: Smithsonian Institution. 1904.

THIS supplement includes the years 1898 to the end of 1902, and preserves the same sub-divisions as were adopted in the main work. It thus contains the titles of new chemical books and academic dissertations, and also new editions published in the above years, arranged in separate classes according to the special nature of their contents, the majority of the works being either in the English, French, German, or Italian languages. Since the death of the author in 1903, while the book was in press, Mr. Axel Moth, of the New York Public Library, has prepared an alphabetical subject index for the supplement, which affords a means of readily ascertaining the titles of recent publications dealing with practically any subject of interest to chemists.

Traité Élémentaire de Physico-Chimie. ("An Elementary Treatise on Physical Chemistry.") By EMM. POZZI-ESCOFF. Paris: Ch. Béranger. 1905.

IT must be seldom indeed that a book issues from the press disfigured as this is by so many misprints. The cases of incorrectly spelt names reach an almost incredible number. Thus we find such specimens as "Latmier-Clarck," "Arenius," "Debieune," "Baknis Roosevelt," "Kohlrauch," "Kelvin," "Van der Waal," "Stass," and though these names are so well known to chemists that the errors are not perhaps of much real consequence, the matter assumes a somewhat different aspect when we find Proust's hypothesis ascribed to Proust, who, moreover, is described as an English chemist, whereas the real Proust was a native of Angers. The same extraordinary carelessness extends to many of the chemical equations; taking, as an example, those on page 47, where the principle of the construction of an equation is illustrated by the action of potassium bichromate on ferrous chloride; in the equation and the few lines of explanation following it there are no fewer than ten separate errors, the result

being that a beginner would probably be hopelessly puzzled. In the text there is to be found no compensating lucidity or novelty of the treatment of the recent wonderful developments of physical chemistry, unnecessary attention being paid to the exposition of exploded theories. Moreover, quite apart from printer's mistakes, there are many examples of actually incorrect statements, some of them of a serious nature; for instance, in the discussion of the constants of dissociation, no definition or explanation whatever is given of the meaning of K when this symbol is first introduced, though some hundred pages later, separated by totally irrelevant matter, we find a short definition of it as an ionisation constant. There being no alphabetical index to refer to, on a first reading the reader could only regard the values as so many numbers; nor are they even the correct numbers, for though given as K they are really the values of $K \times 10^3$; also, in the case of maleic and fumaric acids the constants relate to different dilutions and are thus totally misleading. These and other equally glaring mistakes show how very much revision is necessary before the book can fulfil its purpose of raising the intellectual level of the masses of French chemists, which the author states in the preface was the special aim he kept before him.

The Chemistry of Gas Manufacture. A Practical Handbook on the Production, Purification, and Testing of Illuminating and Fuel Gas, and on the By-products of Gas Manufacture. By W. J. ATKINSON BUTTERFIELD, M.A., F.I.C. Third Edition, with Illustrations. Volume I. *Materials and Processes.* London: Charles Griffin and Company, Ltd. 1904. Pp. 257.

THIS handbook has been revised and enlarged to such an extent that it can no longer be published conveniently as a single volume; therefore it was decided to publish the portion treating of the materials and processes of gas manufacture at once, to be followed by a second volume on "The Testing and Use of Gas."

The volume now before us, Part I., is divided into seven chapters. The first chapter deals with the raw materials of gas manufacture, the chief of which is, of course, coal; though cellulose, wood, peat, &c., also claim a certain amount of attention. Chapters II. and III. are devoted wholly to coal-gas, and all the various artifices and appliances used in its manufacture and purification.

Chapter IV. is on carburetted water gas and its method of manufacture; in this connection we must express our surprise that the important and well known "Mond" process is not given; in fact the only reference we have been able to find to it is on p. 125, where mention is made of the amount of ammonia obtained from the Mond gas producers.

Chapter V. is on oil-gas, and here we have several processes described, such as those of Pintsch, Pope, Keith, Tatham, and others.

Enriching by light oils is the subject of Chapter VI., while in Chapter VII. we find the final details of the manufacture and sundry schemes for making and enriching gas.

The book will no doubt be useful to those engaged in gas making, as it is clearly written and well arranged. There is a table of contents, and an index of thirteen pages.

Analysis of Foods, and the Detection of Adulteration. ("Analyse des Matières Alimentaires et Recherche de Leurs Falsifications.") By CH. GIRARD, with the collaboration of MM. Sangle-Ferrière, de Brévaux, Truchon, V. Genin, Pons, de Raczkowski, Leys, Froidevaux, Cuniasse, and Lefaye. Second Edition, considerably enlarged. Paris: Vve. Ch. Dunod. 1904. Pp. 871.

THE success achieved by the first edition of this work has encouraged the author to bring out a much larger second edition; the new volume contains nearly 200 pages more than the old one. All the original articles have been supplemented and brought up to date, and the very latest

apparatus and methods for food analysis are fully described. New articles have been added on the analysis of water, milk, jam, &c. Without going through the whole list, we may point out that this volume deals with the examination of all kinds of foods and drinks; wine, beer, cider; bread, butter, cheese; pastry, coffee, cocoa, sugars, spices, colours, and soldering materials, &c.

Independently of the chemical analysis proper, there is a section on bacteriology, while the bibliographical portion is well conceived and arranged. Altogether we have a work of considerable importance and of undoubted value to those engaged in food analysis.

CHEMICAL NOTICES FROM FOREIGN SOURCES.

NOTE.—All degrees of temperature are Centigrade unless otherwise expressed.

Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences. Vol. cxxxix., No. 21, November 21, 1904.

Constitution of Ricinine.—L. Maquenne and L. Philippe.—In a former paper the authors described the formation of what they believed to be a methyloxypyridone from ricinine. They find that this substance is a very feeble base, but its bromo- and nitro-derivatives are distinctly acid in character. Phosphorus pentachloride converts it into a dichloropyridine, $C_5H_3Cl_2N$. The formation of this compound shows that methyloxypyridone has lost a methyl group during chlorination, and therefore the latter must have been attached to the nitrogen atom and not to the carbon of the chain. This dichloropyridine can be reduced to pyridine by means of hydriodic acid and red phosphorus. The authors conclude that methyloxypyridone is a derivative of a hypopyridine in which a methyl group is attached to the nitrogen atom, and therefore that—

is the structural formula of ricinine, and—

of methyloxypyridone.

Chemical Composition of Radio-active Gaseous Mixtures arising from Hot Springs.—Ch. Moureu.—Analyses of several of these mixtures are given. They all contain helium, as would be expected from recent researches upon the production of helium by spontaneous change of the radium emanation. The author proposes later to estimate the helium in these mixtures at different stages of the decay of the radio-activity.

Influence of the Nature of the Anode upon the Electrolytic Oxidation of Potassium Ferrocyanide.—André Brochet and Joseph Petit.—When potassium ferrocyanide is electrolysed, potassium ferricyanide, oxygen, and hydroferrocyanic acid appear at the positive pole. If the anode is a metal which can be attacked by the anion $[\text{Fe}(\text{CN})_6]^{4-}$, the corresponding ferrocyanide is produced, the quantity of potassium ferricyanide simultaneously formed varying with the metal used. Results of experiments, using various metals as anode, are given, and the metals classified according to their behaviour towards the ion $[\text{Fe}(\text{CN})_6]^{4-}$.

Complexity of Dissolved Sulphates.—Albert Colson.—A solution was prepared containing 0.75 molecule of

CuSO_4 in two litres of water; the lowering of the freezing-point was found to be 0.70° . The copper was then precipitated by an exact amount of H_2S , and the lowering of the freezing-point of the sulphuric acid solution was determined. It was found to be 1.51° , i.e., twice that of the copper sulphate solution. Since by analysis 1 atom of copper corresponds to 1 molecule of sulphuric acid, the formula of the dissolved metallic salt must be $(\text{CuSO}_4)_2$. Similar results were obtained with other metallic sulphates.

The Influence of certain Substances in Promoting or Retarding the Production of Rust.—L. Lindet.—Some metals, such as copper, when placed with iron in aerated water, promote the formation of rust; others—such as lead, zinc, and principally arsenic—retard its formation. The author finds that these effects are really due to the solution of traces of the hydroxide of the metal in the water. He discusses the formation of rust in tin-plated or galvanised iron vessels containing impure alcohol.

Action of Iodine and Yellow Oxide of Mercury upon Acids of the Ethylene Series.—J. Bougault.—This reagent does not affect acids of this series having the general formulæ $\text{R}-\text{CH}-\text{CH}-\text{COOH}$ or $\text{R}-\text{C}(\text{CH}_2)-\text{COOH}$. Acids with a β -ethylene linking yield iodo-lactones of the general type $\text{R}-\text{CH}-\text{CHI}-\text{CH}_2-\text{CO}$

The formation of these lactones gives a rigorous and easy method of separating the β -acids from the $\alpha\beta$ -acids which are often mixed with them. The β -acids can be re-generated from the lactones by means of zinc and acetic acid.

Action of Hydrobromic and Hydrochloric Acids upon Triacetin.—R. de la Acena.—The preparation and properties of several new halogen compounds of triacetin are described.

Action of Pyridine and Quinoline Bases upon Bromo-succinic and Dibromo-succinic Ethers.—Louis Dubreuil.—The three bases studied—pyridine, quinoline, and quinaldine—act in the same way upon these ethers, i.e., they remove the hydrobromic acid, and cause the formation of non-saturated ethers. At the same time quinoline and quinaldine are transformed into basic hydrobromides, similar to the basic hydrochloride of aniline recently described by Selivanof.

Theory of Dyes.—Jules Schmidlen.—According to this theory, the molecule of a true dye contains an endothermic group with double aliphatic carbon linkings (a chromophore) which is the cause of the colour, and also a very exothermic group (an auxochrome), the presence of which renders the endothermic group stable.

Action of Reduced Nickel upon Aromatic Ketones.
A New Synthesis of Aromatic Hydrocarbons.—Georges Darzens.—The reducing effect of the nickel depends upon how it has been prepared. It is more powerful when it is finely divided and when it has been prepared by reducing the oxide, NiO , at a low temperature. Thus aromatic ketones of the general formula $\text{C}_6\text{H}_5-\text{CO}-\text{R}$, hydrogenised by nickel which had been prepared at 300° , gave compounds having the formula $\text{C}_6\text{H}_5-\text{CH}_2-\text{R}$. But when nickel prepared at a much lower temperature was used, the corresponding hexahydro-derivatives were obtained.

No. 22, November 28, 1904.

Possibility of Chemical Reactions.—M. de Forcrand.—According to thermo-chemistry, a chemical reaction is possible if q (heat evolved) > 0 . According to thermodynamics, the condition of possibility is that $q - q' > 0$; where q' is a small correction which it is practically impossible to determine. Thus the thermo-chemical criterion is the only one of practical value. A similar paper follows, by the same author, on the prediction of chemical reactions.

The Colloidal State of Matter.—G. E. Malitano.—The author considers that matter in the colloidal state consists of an electrolyte dissociated into ions, and of insoluble molecules grouped round these ions.

MISCELLANEOUS.

King's College.—Department of General Pathology and Bacteriology.—Director: Professor Hewlett, M.D., M.R.C.P., D.P.H.; Demonstrator: H. S. Willson, B.A., M.B., D.P.H.

Examinations of the Institute of Chemistry.—Class in Bacteriology and Chemical Bacteriology for these Examinations. Candidates preparing for admission to the Intermediate Examination of the Institute may take Bacteriology as an optional subject. The course consists of demonstrations and practical work on two afternoons a week (or an equivalent amount) during one term (ten to twelve weeks). Subjects:—Nature of cells; the microscope and methods; general biology of bacteria; staining and culture methods; typhoid and *B. coli*; anthrax; tubercle; diphtheria; *B. enteritidis sporogenes*; bacteriological examination of milk and foods, air, water, and sewage; the yeasts and fermentation; moulds. The A.I.C. Examination.—The course for candidates preparing for the Final (A.I.C.) Examination in the Branch of Biological Chemistry consists of demonstrations and practical work two afternoons a week (or an equivalent amount) during two terms. Subjects:—As for the Intermediate, but treated more fully, and in addition enzymes, analysis of yeasts, fermentations, testing of filters, nitrification, certain chemical separations, e.g., indol, pigments, &c.

Evening Classes.—A course in practical and clinical bacteriology will be held every Monday evening (January to March) from 6.30 to 8.30, commencing January 9th. The course will consist of lectures, demonstrations, and practical work; in the latter, the members of the class will make for themselves permanent preparations of the chief pathogenic micro-organisms, and will carry out the usual manipulations employed in bacteriological investigations. Names should be sent in as soon as possible to the Secretary, or to Professor Hewlett, as the class will not be held if less than six students join. Syllabus:—Morphology and biology of the bacteria; the cultivation and isolation of organisms, culture media; anthrax; tubercle, tubercle of milk; diphtheria; typhoid and *B. coli*; anaerobic bacteria; principles of the bacteriological examination of water; fermentation. Practical Work:—Types of organisms, preparation of cover-glass specimens; cultures and plate cultivations; Gram's method; anthrax; tubercle; diphtheria; typhoid and *coli*; *B. enteritidis sporogenes*, &c.; examination of water; yeasts.

Decomposition of Carbon Dioxide under the Influence of Light.—A. Bach.—Euler has found that uranium acetate solutions are reduced in sunlight both in the absence of carbon dioxide and on passing nitrogen through them, but the author cannot obtain such reduction if carbon dioxide is absent, or if carbon dioxide is led through the solution in the dark. If, however, the carbon dioxide is introduced into the solution in direct sunlight, the uranium acetate is decomposed, giving a mixture of uranous and uranic hydroxides. Possibly these contradictory results are due to the presence of some foreign substance in one or other of the uranium acetate preparations employed.—*Berichte*, xxviii., No. 15.

The Part Played by Diaphragms in the Electrolysis of Saline Solutions.—W. Hittorf.—The different substances in general use as diaphragms play various rôles in electrolysis. Porcelain and agar-agar give rise to an electric endomose, such that the solution that remains undecomposed is only displaced in the direction of the positive current; on the other hand, intestinal membrane, as well as albumenoid substances and parchment paper, divide the solutions of several salts into a

more concentrated portion and a dilute portion; the former goes in the direction of the negative current, the latter in the positive direction, and both have a considerable speed. However, this phenomenon does not take place if the concentration of the solution reaches and passes a certain limit, which depends on the nature of the salt. All salts do not undergo this division; the alkaline salts behave, with these substances, in the same manner as they do with porcelain or agar-agar; they only give rise to a slight endomose, at a constant concentration, and in the direction of the positive current.—*Zeit. Physik. Chem.*, vol. xliii., p. 239.

Researches on Nitrifying Microbes.—E. Boullanger and L. Massol.—The authors have confirmed the fact that in nitrous fermentations we can replace the carbonate of ammonia with a carbonate of any other common base. The nitrification succeeds also with a large number of ammoniacal salts; it is slight with the arseniate, iodide, citrate, and oxalate, but proceeds very well with the borate and fluorhydrate; further, the nitric ferment oxidises nearly all the nitrites. It has been observed up to the present time that on sowing the nitrous and nitric ferments in an ammoniacal solution, the nitric fermentation begins only when the nitrous fermentation is completed. This phenomenon appears to be due to the action of the ammonia on the nitric ferment, of which it retards the reproduction, without interfering with its oxidising functions. Above 10 milligrams of ammonia per litre the retardation of the nitrification becomes marked. We see, moreover, that symbiosis is produced in the bacteria beds for the purification of waste waters; the formation of nitrites being so small. After having obtained a culture with the two microbes sowed simultaneously, we replace, aseptically, the exhausted liquid with an equal quantity of fresh broth; thus we obtain perfect symbiosis with a very slight production of nitrite; we may even obtain symbiosis at once by sowing the two ferments very copiously in the small rotating glass vessels described in a previous paper.—*Ann. de l'Inst. Pasteur*, vol. xviii., No. 3, pp. 181–196.

Abnormal Electrolysis.—P. Walden.—There is a large number of bodies, simple and compound, which without being either salts, acids, or bases, and consequently not capable of being looked upon as true electrolytes, are nevertheless, under many conditions, good conductors of the electric current; they appear to undergo electrolytic dissociation in a remarkable manner, which is shown by the energy and speed of the reactions to which they give rise when they are dissolved in certain ionising solvents; for example, liquid SO_2 , SO_2Cl_2 , AsCl_3 , &c. Of such a nature are the halogen elements in the free state; the compounds they form between themselves, their compounds with the metalloids, the tertiary bases of nitrogen, the carbinols, the carbides of hydrogen, the alcoholic bromides and iodides, and the acid chlorides and bromides. The author designates all these bodies by the name of "abnormal electrolytes," and has examined their electrolytic dissociation with a view to determining by measurements of their conductivity the nature of the ions they furnish. By this means he has arrived at the following conclusions:—1. The halogens (Br, I) give not only anions, but also cations, Br^- and Br^{++} , I^- and I^{++} . 2. The metalloids (P, As, Sb, Sn, S) also give cations, P^{++} and P^{+++} , As^{++} , Sb^{++} and Sb^{+++} , Sn^{++} , S_2^{++} . 3. The tertiary azotised bases (quinoline, pyridine, picoline) give bivalent cations, $(\text{RN})^{++}$. 4. Dimethylpyrone gives a bivalent cation, $(\text{C}_7\text{H}_5\text{O}_2)^{++}$. 5. The carbinols and the corresponding bromides and iodides give univalent cations, $(\text{C}_6\text{H}_5)_2\text{C}^+$. 6. The existence of acid cations, $(\text{CH}_3\text{CO})^+$, or PO^{++} , appears to be very probable.—*Zeit. Physik. Chem.*, vol. xliii., p. 385.

MEETINGS FOR THE WEEK.

TUESDAY, Jan. 3rd
THURSDAY, .. 5th
SATURDAY, .. 7th

Royal Institution, 3 (Christmas Lectures, adapted to a Juvenile Auditory). "Ancient and Modern Methods of Measuring Time" (Experimentally Illustrated), by Henry Cunningham, C.B., &c.
